BALANCE. For the measurement of the "*mass*" of (*i.e.*, of the quantity of matter contained in) a given body we possess only *one* method, which, being independent of any supposition regarding the nature of the matter to be measured, is of perfectly general applicability. The method—to give it at once in its customary form—consists in this, that after having fixed upon a *unit mass*, and procured a sufficiently complete set of bodies representing each a known number of mass-units (a "set of weights"), we determine the ratio of the *weight* of the body under examination to the *weight* of the unit piece of the set, and identify this ratio with the ratio of the *masses*. Machines constructed for this particular *modus* of weighing are called *balances*. Evidently the weight of a body as determined by means of a balance—and it is in this sense that the term is always used in everyday life, and also in certain sciences, as, for instance, in chemistry—is independent of the magnitude of the force of gravity; what the merchant (or chemist) calls, say, a "pound" of gold is the same at the bottom as it is at the top of Mont Blanc, although its real weight, *i.e.*, the force with which it tends to fall, is greater in the former than it is in the latter case.

To any person acquainted with the elements of mechanics, numerous ideal contrivances for ascertaining which of two bodies is the heavier, and for even determining the ratio of their weights, will readily suggest themselves; but there would be no use in our noticing any of these many conceivable balances, except those which have been actually realised and successfully employed. These may be conveniently arranged under six heads.

1. *Spring Balances.*—The general principle of this class of balances is that when an elastic body is acted upon by a weight suspended from it, it undergoes a change of form, which, *cæteris paribus*, is the greater the greater the weight. The simplest form of the spring balance is a straight spiral of hard steel (or other kind of elastic) wire, suspended by its upper end from a fixed point, and having its lower end bent into a hook, from which, by means of another hook crossing the first, the body to be weighed is suspended,—matters being arranged so that even in the empty instrument the axis of the spiral is a plumb-line. Supposing a body to be suspended at the lower hook, it is clear that the point where the hooks intersect each other will descend from the level it originally occupied, and that it must fall through a certain height h before it can, by itself, remain at rest. This height, provided the spiral was not strained beyond its limit of elasticity (*i.e.*, into a permanent change of form), is proportional to the *weight* P of the body, and consequently has to the mass M the relation $h = cg\text{M}$, where c is a constant and g the acceleration of gravity. Hence, supposing in a first case h and M to have been h' and M′, and in a second case, h'' and M″, we have $h' : h'' :: g\text{M}' : g''\text{M}''$; and it is only as long as g is the same that we can say $h' : h'' :: \text{M}' : \text{M}''$. Spring balances are very extensively used for the weighing of the cheaper articles of commerce and other purposes, where a high degree of precision is not required. In this class of instruments, to combine compactness with relatively considerable range, the spring is generally made rather strong; and sometimes the exactitude of the reading is increased by inserting, between the index and that point the displacement of which serves to measure the weight, a system of levers or toothed wheels, constructed so as to magnify into convenient visibility the displacement corresponding to the least difference of weight to be determined. Attempts to convert the spring balance into a precision instrument have scarcely ever been made; the only case in point known to the writer is that of an elegant little instrument constructed by Professor Jolly, of Munich, for the determination of the specific gravity of solids by immersion, which consists of a long steel-wire spiral, suspended in front of a vertical strip of silvered glass bearing a millimetre scale. To read off the position of equilibrium of the index on the scale, the observing eye is placed in such a position that the eye, its image in the glass, and the index are in a line, and the point on the scale noted down with which the index apparently coincides.

2. *Chain Balances.*—This invention of Wilhelm Weber's having never, so far as we know, found its way into actual practice, we confine ourselves to an illustration of its principle. Imagine a flexible string to have its two ends attached to the two fixed points C and D (fig. 1), forming the ter-

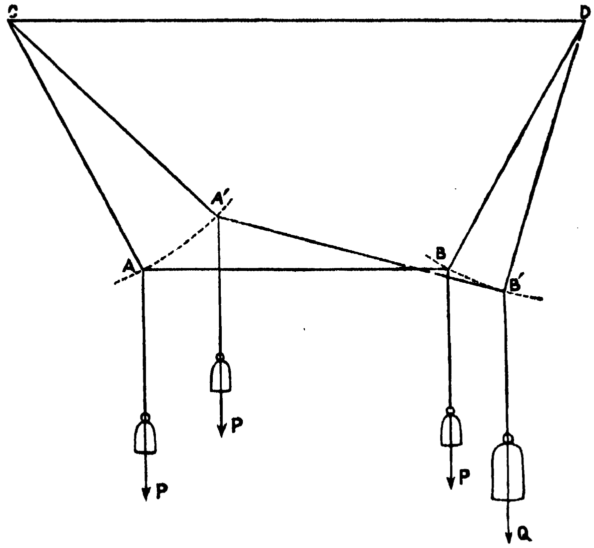

Fig. 1.—Diagram illustrating Chain Balance.

minal points of a horizontal line CD shorter than the string. Suppose two weights to be suspended, the one at a point A, the other at a point B of the string; the form of the polygon CDBA will depend, *cæteris paribus*, on the ratio of the two weights. Assuming, for simplicity's sake, CA to be equal to DB, then, if the weights are equal, say, each = P units, the line AB will be horizontal. But if now, say, the weight at B be replaced by a heavier weight Q, the point A will ascend through a height h, the point B will descend through a lesser height h' in accordance with equation $\text{P}h = \text{Q}h'$, and the angle between what is now the position of rest of the base line A′B′, and the original line AB will depend on the ratio of P : Q. The exact measurement of this angle would be difficult, but it would be easy to devise very exact means for ascertaining whether or not it was horizontal, and, if not, whether it slanted down the one way or the other; and thus the instrument might serve to determine whether P was equal to, or greater or less than, Q; and this obviously is all that is required to convert the contrivance into an exact balance.

3. *Lever Balances.*—This class of balances, being more extensively used than any other, forms the most important division of our subject. There is a great variety of lever balances; but they are all founded upon the same principles, and it is consequently expedient to begin by summing up these into one general theory.

Theory of the Lever Balance (fig. 2).—In developing the "theory" of a machine, the first step always is and must be that we substitute for the machine as it is a *fictitious* machine, which, while it closely corresponds in its working to the actual thing, is free from its defects. In this sense what now follows has to be understood. Imagine

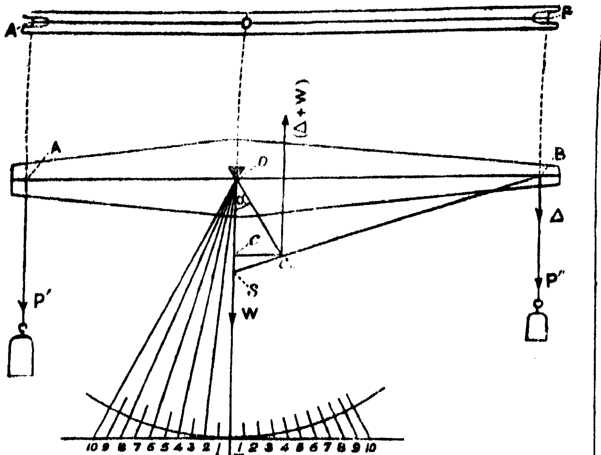

FIG. 2.—Diagram illustrating the theory of the Lever Balance.

an *inflexible beam* suspended from a stand in such a manner that, while it can *rotate freely* about a certain horizontal axis fixed in its position with respect to both the stand and the beam, and passing through the latter somewhere *above* its centre of gravity, it cannot perform any other motion. Imagine the beam at each end to be provided with a vertical slit, and each slit to be traversed by a rigid line fixed in the beam in such a situation that both lines are parallel to, and in one and the same plane with, the axis of rotation; and suppose the mass of the beam to be so distributed that the line connecting the centre of gravity S with its projection O on the axis of rotation stands perpendicular on that plane. Suppose now two weights, P′ and P″, to be suspended by means of absolutely flexible strings, the former from a point A on the rigid line in the left, the other from a point B on the rigid line in the right slit, and clearly, whatever may be the effect, it will *not* depend on the length of the strings. Hence we may replace the two weights by two material points situated in A and B, and weighing P′ and P″ respectively. But two such points are equivalent, statically, to one point (weighing P′ + P″) situated somewhere in D within the right line connecting A with B. Suppose the beam to be arrested in its "*normal position*" (by which we mean that position in which AB stands horizontal and the line SO is a plumb-line), and then to be released, the statical effect will depend on the situation of the point D, and this situation, supposing the ratio $l' : l''$ to be given, on the ratio P′ : P″. If $P'\,l' = P''\,l''$, D lies in the axis of rotation; the beam remains at rest in its normal position, and, if brought out of it, will return to it, being in *stable* equilibrium. This at once suggests two modes of constructing the instrument and two corresponding methods of weighing.

First Method.—We so construct our instrument that while l' is constant, l'' can be made to vary and its ratio to l' be measured. In order then to determine an unknown weight P′, we suspend it at the point pivot A; we then take a standard weight P″ and, by shifting it forwards and backwards on AB, find that particular position of the point of suspension B, at which P″ exactly counterpoises P′. We then read off $\frac{l''}{l'}$, and have $P' = P''\frac{l''}{l'}$. But, practically, the body to be weighed cannot be directly suspended from A, but must be placed in a *pan* suspended from A, and consequently the weight p_0 of the pan and its appurtenances would always have to be deducted from the total weight P′, as found by the experiment, to arrive at the weight of the object $p = P' - p_0$. Hence, what is actually done in practice is so to *shape the right arm that its back coincides with the line AB, and to lay down on it a scale, the degrees of which are equal to one another, and to l' (or some convenient submultiple or multiple of l') in length, and so to adjust* p_0 and number the scale, that when the sliding weight P″ is suspended at the zero-point, it just counterpoises the pan; so that when now it is shifted successively to the points 1, 2, 3 . . . p, it balances exactly 1, 2, 3 . . . p units of weight placed in the pan. This is the principle of the common *steel-yard*, which, on account of the rapidity of its working, and as it requires only *one* standard weight, is very much used in practice for rough weighings, but which, when carefully constructed and adjusted, is susceptible of a very considerable degree of precision. In the case of a precision steel-yard, it is best so to distribute the mass of the beam that the right arm balances the left one + the pan, to divide that arm very exactly into, say, only 10 equal parts, and instead of one sliding weight of P″ units to use a set of standards weighing P″, $\frac{1}{10}$ P″, $\frac{1}{100}$ P″, $\frac{1}{1000}$ P″, &c. The great difficulty is to ensure to the heavier sliding weights a sufficiently constant position on the beam. To show the extent to which this difficulty can be overcome it may be stated that in an elegant little steel-yard, constructed by Mr Westphal of Celle (for the determination of specific gravities), which we had lately occasion to examine, even the largest rider, which weighs about 10 grammes, was so constant in its indications that, when suspended in any notch, it always produced the same effect to within less than $\frac{1}{3000}$th of its value.

Second Method.—We so construct our instrument that both l' and l'' have constant values, and are nearly or exactly equal to each other, and provide it with pans, whose weights p_0' and p_0'' are so adjusted against each other that $p_0'l' = p_0''l''$, and, consequently, the empty instrument is at rest in its normal position. We next procure a sufficiently complete set of weights, *i.e.*, a set which, by properly combining the several pieces with one another, enables us to build up any integral multiple of the smallest difference of weight δ we care to determine, a set, for instance, which virtually contains any term of the series 0·001, 0·002, 0·003 . . . . 100·000 grammes. In order now to determine an unknown weight p', we place it, say, in the left pan, and then, by a series of trials, find that combination of standards p'' which, when placed in the right pan, establishes equilibrium to within $\pm\,\delta$. Evidently—

$$p' = \frac{(p'' \pm \delta)l''}{l'} \quad . \quad . \quad . \quad (1).$$

In the case of purely *relative* weighings, there is nothing to hinder us from adopting $\frac{l''}{l'}$ units $\left(e.g., \frac{l''}{l'}\text{ grammes}\right)$ as our unit of mass, and simply to identify the relative value of p' with the number p''. But even if we want to know the absolute value of p' in true grammes, we need not know the numerical value of $\frac{l''}{l'}$. All we have to do is, after having determined the value of p' in terms of $\frac{l''}{l'}$, to *reverse* the positions of object and standards, and, in a similar manner, to ascertain the value p_1'' which *now* counterpoises the unknown weight p' lying in the *right* pan. Obviously $p' = p''\frac{l''}{l'} = p_1''\frac{l'}{l''}$ whence $(p')^2 = p''p_1''$, and $p' = \sqrt{p''p_1''}$, for which expression, if the two arms are very nearly of equal length, we may safely substitute $p' = \frac{1}{2}(p'' + p_1'')$. Or, instead of at once finding the counterpoise for p' in standards, we may first counterpoise it by means of shot or other

material placed in the opposite pan, and then find out the number of grammes p'' which has to be *substituted* for p' to again establish absolute equilibrium. Evidently $p' = p''$. This (in reference to the ideal machine meant to be realised) is the theory of the *common balance* as we see it working in every grocer's shop, and also that of the modern *precision balance*, which, in fact, is nothing but an equal-armed beam and scales refinedly constructed. In the case of the latter class of balances the inconvenience involved in the use of very small weights may be avoided (and is generally avoided) by dividing the right arm of the beam, or rather the line AB, into 10 equal parts, and determining differences of less than, say, 0·01 gramme by means of a sliding weight possessing that value. But evidently, instead of dividing the whole length of the right arm, it is better to divide some portion of it which is so situated that the rider can be shifted from the very zero to the "10," and so to adjust the rider, that when it is shifted successively from 0 to 1, 2, 3 . . . n it is the same as if 1, 2, 3 . . . n tenths of its weight were placed in the right pan. The rider in this case must, of course, form part and parcel of the beam. It is singular that none of our precision-balance makers have ever thought of this very obvious improvement on the customary system. In the very excellent instrument made by Messrs Becker and Company of New York, this, it is true, is realised partially in a rider weighing 12 milligrammes and a beam divided into 12 equal parts (instead of 10 and 10 respectively); but this does not enable one to shift the rider to where it would indicate from 0 to say $\frac{3}{10}$ or $\frac{4}{10}$ of a milligramme. Whichever of these modes of weighing we may adopt, we must have an arrangement to see whether the balance is in its normal position, and it is desirable also to have some means to enable us, in the course of our trials, to form at least an idea as to the additional weight which would have to be added to the standards on the pan (or to be taken away) in order to establish equilibrium. To define the normal position, all that is required is to provide the beam with a sufficiently long "needle," the axis of which is parallel to the line OS, and which plays against a circular limb fixed to the stand and constructed so that the upper edge of the limb coincides very nearly with the path of the point of the vibrating needle, and to graduate the limb so that, as fig. 2 shows, the zero point indicates the normal position of the beam. In order to see how the graduation must be made to be as convenient as possible a means for translating deviations of the needle into differences of weight, let us assume the balance to be charged with P′ grammes from A and with $P'' + \Delta$ grammes from B, and P′ and P″ to satisfy the equation $P'l' = P''l''$. The two weights P′ and P″ being equivalent to one point $P' + P''$ in the axis of rotation, the effect is the same as if these two weights did not exist and the beam was only under the influence of two weights, viz., the weight W of the beam acting in S and the weight Δ acting in B. But this comes to the same as if both W and Δ were replaced by one point weighing $W + \Delta$, and situated somewhere at C_0 between, and on a line with, B and S. Hence, supposing the beam to be first arrested in its normal position and then to be left to itself, the right arm will go down and not be able by itself to remain at rest before it has reached that position in which C_0 lies vertically below the axis of rotation. *Cæteris paribus* C_0 will be the nearer to B, and consequently the angle α, through which the beam (and with it the needle) has to turn to assume what now is its position of stable equilibrium, will be the greater the greater Δ is, and for the same Δ and W the angle of deviation will be the greater the less the distance s of the centre of gravity of the beam S is from the axis of rotation. The former proposition enables one in a given case to form an idea of the amount Δ which has to be taken away from the right pan to establish equilibrium. To find the exact mathematical relation between Δ and the corresponding angle α, let us remember that the position of C_0 is the same whatever may be the direction of gravity with regard to the beam. Assuming gravity to act parallel to OS, we have $(W + \Delta)\,\overline{CC_0} = \Delta l''$, where C stands for the projection of C_0 on $\overline{OS}$. Assuming, secondly, gravity to act parallel to the line $\overline{OB}$, we have $(W + \Delta).\ \overline{CO} = W.\ \overline{OS}$;

$$\therefore\ \frac{\overline{CC_0}}{\overline{CO}} = \tan \alpha = \frac{\Delta l''}{Ws}\quad .\quad .\quad .\quad .\quad (2).$$

Obviously, the right way of graduating the limb is to place the marks so that their radial projections on the tangent to the circle at the zero-point divide that line into parts of equal length. In the ordinary balance where l'' is a constant, the factor $\frac{l''}{Ws}$ has a constant value, which can be determined by *one* experiment with a known Δ—always supposing that in the instrument used the requirements of our theory were exactly fulfilled. In good precision balances they *are* fulfilled, to such an extent at least, that although the factor named is not absolutely constant, but a function of P, it can be looked upon as a *relative* constant, so that by determining the deviations produced by a given Δ, say $\Delta = 1$ milligramme, for a series of charges (*i.e.*, values of P″), one is enabled to readily convert deviations of the needle, as read off on the scale, into differences of weight. This method is very generally followed in the exact determinations of weights as required in chemical assaying, in the adjusting of sets of weights, &c. Only, instead of letting the needle come to rest and then reading off its position, what is done is to note down 2, 3, 4 . . . n consecutive excursions of the needle, and from the readings ($a_1, a_2, a_3, a_4 \ldots a_n$) to calculate the position a_0 where the needle *would* come to rest if it were allowed to do so. It being understood that the readings must be taken as positive or negative quantities according as they lie to the left or to the right of the zero-point, a_0 might be identified with *any* of the sums—

$$\tfrac{1}{2}(a_1 + a_2),\quad \tfrac{1}{2}(a_2 + a_3),\ \ldots\ldots\ \tfrac{1}{2}(a_{n-1} + a_n),$$

but clearly it is much better to calculate a_0 by taking the mean of these quantities, thus—

$$a_0 = \frac{a_1 + a_n + 2\,(a_2 + a_3\ \ldots\ + a_{n-1})}{2\,(n-1)};$$

and it is also easily seen that to eliminate as much as possible the influences of the resistance of the air and (let us at once add by anticipation of what ought to be reserved for a subsequent paragraph) of the friction in the pivots of the balance, it is expedient to let n be an *odd* number. Theoretically this method is, of course, *not* confined to small Δ's, and it is easy to conceive a balance in which the limb is so graduated that it gives directly the weight of an object placed in the right pan; this is the principle of the *Tangent Balance*, a class of instruments which used to be very generally employed for the weighing of letters, parcels, &c., but is now almost entirely superseded by the spring balance.

After having thus given a general theory of the *ideal*, let us now pass to the *actual* instrument. But in doing so we must confine ourselves mainly to the consideration of that particular class of instruments called precision balances, which are used in chemical assaying, for the adjustment of standard weights, and for other exact gravimetric work.

The *Precision Balance* being, as already said, quite identical in principle with the ordinary "pair of scales," there is no sharp line of demarcation between it and what is usually called "a common balance," and it is equally

impossible to name the inventor of the more perfect form of the instrument. But taking the precision balance in what is now considered its most perfected form, we may safely say that all which distinguishes it from the common balance proper is, in the main, the invention of the late Mr Robinson of London. In Robinson's, as in most modern precision balances, the beam consists of a perforated flat rhombus or isosceles triangle, made in one piece out of gun-metal or hard-hammered brass. The substitution for either of those materials of *hard steel* would greatly increase the relative inflexibility of the beam, but, unfortunately, steel is given to rusting, and, besides, is apt to become magnetic, and has therefore been almost entirely abandoned. The perforations in the beam are an important feature, as they considerably diminish its weight (as compared with what that would be if the perforations were filled up) without to any great extent reducing its relative solidity. In fact, the loss of carrying power which a solid rhombus suffers in consequence of the middle portions being cut out, is so slight that a very insignificant increase in the size of the minor diagonal is sufficient to compensate for it. *Why* a balance beam should be made as light as possible is easily seen; the object (and it is as well here to say at once, the *only* object) is to diminish the influence of the unavoidable imperfections of the central pivot. To reduce these imperfections to a minimum, the beam in all modern balances is supported on a polished horizontal plane of *agate* or *hard steel* fixed to the stand, by means of a perfectly straight "*knife-edge*," ground to a prism, of hard steel or agate, which is firmly connected with the beam, so that the edge coincides with the intended axis of rotation. In the best instruments the bearing plane is continuous, and the edge rests on it along its entire length; in less expensive instruments the bearing consists of two separate parts, of which the one supports the front end, the other the hind end of the edge. Every complete balance is provided with an "arrestment," one of the objects of which is, as the name indicates, to enable one to arrest the beam, and, if desired, to bring it back to its normal position; but the most important function of it is to secure to *every point of the central edge* a perfectly fixed position on its bearing. So far all modern precision balances agree; but the way in which the *point-pivots* A and B of our fictitious machine are sought to be realised varies very much in different instruments. In Robinson's, and in the best modern balances, the beam is provided at its two extremities with two knife-edges similar to the central one (except that they are turned upwards), which, in intention at least, are parallel to, and in the same plane as, the central edge; on each knife-edge rests a plane agate or steel bearing, with which is firmly connected a bent wire or stirrup, provided at its lower end with a circular hook, the plane of which stands perpendicular to the corresponding knife-edge; and from this hook the pan is suspended by means of a second hook crossing the first, matters being arranged so that, supposing both end-bearings to be in their proper places and to lie horizontally, the working points A′ and B′ of the two hook-and-eye arrangements are vertically below the intended point-pivots A and B on the edges. In this construction it is an important function of the arrestment to assign to each of the two terminal bearings a *perfectly constant* position on its knife-edge. How this is done a glance at figs. 3 and 4 (of

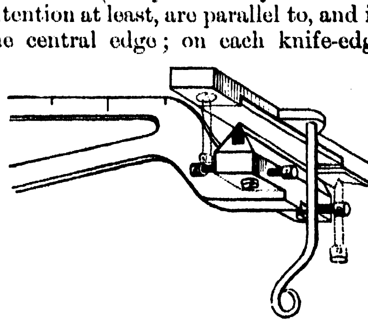

Fig. 3.—Oertling's Balance. End of Beam.

which the former is taken from an excellent instrument constructed by L. Oertling of London, and the latter from an equally good balance, represented in fig. 5, made by Messrs Becker & Co., of New York) shows better than any verbal explanation. But what cannot be seen from these sketches is that the range of the arrestment is regulated, and its catching contrivances are placed, so that when the arrestment is at its highest place, the central edge is just barely lifted from its bearing, and the terminal bearings are similarly lifted from their respective knife-edges, so that the beam is now at rest in its normal position. In other balances, as, for instance, in the justly celebrated instruments of Mr Staudinger of Giessen, Robinson's plane terminal bearings are replaced by roof-shaped ones (fig. 6), so that their form alone suffices to secure to them a fixed position on their knife-edges. Another construction (which offers the great advantage of being easy of execution and facilitating the adjustment of the instrument) is to give to the terminal edges the form of circular rings, the planes of which stand parallel to the central edge, and from which the pans are suspended directly by sharp hooks, so that the points A′ and B′ coincide with A and B respectively. In either case the terminal bearings are independent of the arrestment, which must consequently be provided with some extra arrangement, by means of which the beam, when the central edge is lifted from its support, is steadied and held fast in its normal position. In second and third class instruments even the central edge is made independent of the arrestment, by letting it work in a semi-cylindrical or, what is better, a roof-shaped bearing, which, by its form, assigns to it (in intention at least) a definite position.

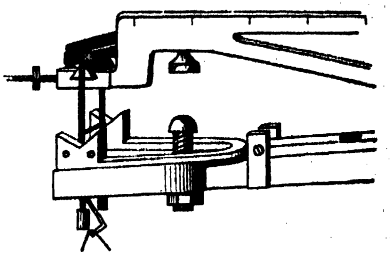

Fig. 4.—Becker's Balance. End of Beam.

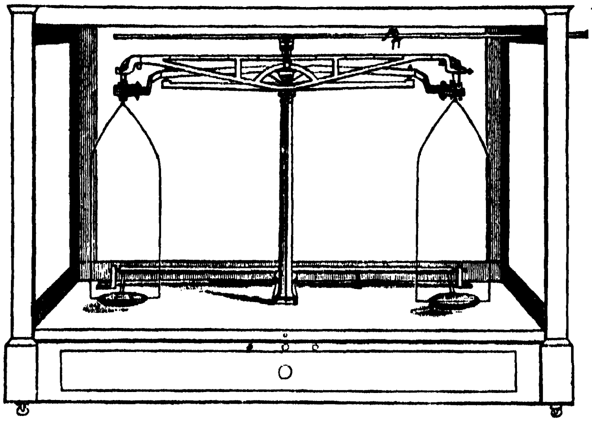

Fig. 5.—Becker's Balance.

Fig. 6.

In order now to develop a complete theory of the precision balance, let us first imagine an instrument, which, for distinctness, we will assume to be constructed on Robinson's model, the knife-edges and bearings, &c., being exactly and absolutely what they are *meant* to be, except that the terminal edges, while still parallel to the axis of rotation, are slightly shifted out of their proper places. Supposing such a balance were charged with $P' = p_0' + p'$ from the left, and $P'' = p_0'' + p''$ from the right knife-edge,—and it is clear that in this case also the charges may be assumed to be concentrated,—P′ in a certain fixed point A on the

left, and P″ in a certain fixed point B on the right edge, and, consequently, the statical condition of the balance is the same as if the weights W, P′, P″ were all concentrated in one fixed point C_0 (fig 7), the position of which, in regard to the beam, is independent of the extent to which the latter may have turned, and independent of the direction of gravity. It is also easily seen that in a given

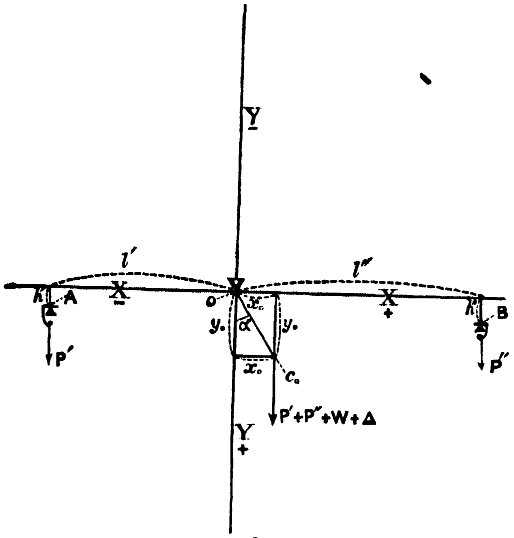

FIG. 7.—Diagram illustrating theory of Precision Balance.

beam the position of C_0 will depend only on P′ and P″, and supposing P′ to remain constant it will change its position whenever P″ changes its value. The point C_0 will in general lie outside of the axis of rotation, and consequently there will in general be only two positions of the beam in which it can remain at rest, namely, first, that position in which C_0 lies vertically above, and, secondly, that position in which it lies vertically below the axis of rotation. Only one of these two positions can possibly lie within the angle of free play which the beam has at its disposal. The second of the two positions, if it is within this angle, can easily be found experimentally, because it is the position of stable equilibrium, which the beam, when left to itself in any but the first position, will always by itself tend to assume. The first position, viz., that of unstable equilibrium, is *practically* beyond the reach of experimental determination. Hence the points A, B, and S must be situated so that, at least whenever $P'l' = P''l''$ exactly or very nearly, the beam *has* a definite position of stable equilibrium, and that this position is within the angle of free play. To formulate these conditions mathematically, assume a system of rectangular co-ordinates, X, Y, Z, to be connected with the beam, so that the axis of the Z coincides with the central edge and the origin with the projection O of the centre of gravity on that edge, while the Y-axis passes through the centre of gravity. Let the values of the co-ordinates of the points A, B, S, C_0 (imagined to be situated as indicated by the figure) be as follows:—

Point	A	B	S	C_0
$x=$	$-l'$	$+l''$	0	x_0
$y=$	h'	h''	s_0	y_0

(The *z's* are evidently of no practical consequence.) To find x_0 and y_0, we need only again apply the reasoning which helped us in the case of the similar problem regarding the ideal instrument. Assuming, then, first, gravity to act parallel to Y, we have $(P' + P'' + W)\,x_0 = P''l'' - P'l'$. Assuming, secondly, gravity to act parallel to X, we have $(P' + P'' + W)\,y_0 = P'h' + P''h'' + Ws$, $\therefore$ for the distance of the common centre of gravity C_0 of the system from the axis of rotation $r = \sqrt{x_0^2 + y_0^2}$, and for the angle α through which the needle, supposing it to start from the zero-point, must turn to reach its position of stable equilibrium—

$$\tan\alpha = \frac{x_0}{y_0} = \frac{P''l'' - P'l'}{Ws_0 + P'h' + P''h''} \quad . \quad . \quad . \quad . \quad (3).$$

If, in particular cases, one or more of the points A, B, S should lie above the X-axis, we need only consider the respective ordinates as being in themselves negative, and the equations (as can easily be shown) remain in force. Taking equation 3, together with what was said before, we at once see that if a balance is to be at all available for what it has been made for, and supposing two of the co-ordinates h', h'' to have been chosen at random, the third must be chosen so that, at least whenever P′ exactly or nearly counterpoises P″, $Ws_0 + P'h' + P''h'' > 0$. For if it were $= 0$, then, in case of $P'l' = P''l''$, the balance would have no definite position of equilibrium, and if it were negative, y_0 would be negative, and the position of stable equilibrium would lie outside the angle of free play. Obviously, the best thing the maker can do is so to adjust the balance that $h' = h'' = 0$ and $l' = l''$, because then the customary method of weighing (see above) assumes its greatest simplicity, and, especially, the factor with which the deviation of the needle has to be multiplied to convert it into the corresponding excess of weight present on the respective pan assumes its highest degree of relative constancy. We speak of a degree of constancy because this factor can never be absolutely constant, for the simple reason that no beam is absolutely inflexible, and consequently h' as well as h'' is a function of P′, and P″ of the form $h = h_0 + \gamma P$, where γ has a very obvious meaning. What is actually done in the adjusting of the best instruments is so to place the terminal edges that, for a certain medium value of $P' + P''$, $h' + h'' = 0$, so that the sensibility of the balance is about the same when the pans are empty as when they are charged with the largest weights they are intended to carry. The condition $l' = l''$ also cannot be fulfilled absolutely in practice, but mechanicians now-a-days have no difficulty in reducing the difference $\frac{l''}{l'} - 1$ to less than $\pm\frac{1}{50000}$ and even a greater value would create no serious inconvenience. We shall therefore now assume our balance to be exactly equal-armed; and, substituting for $h' + h''$ the symbol $2h$, and understanding it to be that (small) value which corresponds to the charge, substitute for equation 3 the simpler expression

$$\tan\alpha = \frac{\Delta . l}{Ws_0 + 2Ph} \quad . \quad . \quad . \quad . \quad (4),$$

which, on the understanding that $P'' = P' + \Delta$, and that Δ is a very small weight, gives the tangent-value corresponding to P and Δ. Sometimes it is convenient to look upon the pans (weighing p_0 each) as forming part and parcel of the beam; the equation then assumes the form—

$$\tan\alpha = \frac{\Delta l}{W's' + 2ph} \quad . \quad . \quad . \quad . \quad (5),$$

where $p = P - p_0$.

In a precision balance the sensibility, *i.e.*, the tangent-value of the deviation produced by $\Delta = 1$, which is

$$\frac{\tan\alpha}{\Delta} = \text{“}a\text{”} = \frac{l}{W's' + 2ph} \quad . \quad . \quad . \quad . \quad (6),$$

must have a pretty considerable value, and at the same time ought to be as nearly as possible independent of the charge. Hence what the equation (4) indicates with reference to a balance to be constructed is, that, so far as these two qualities are concerned, we may choose the weight of the beam as we like; and in regard to the sensibility which the instrument is meant to have when charged to a certain

extent, we have even the free choice of the arm-length, because, whatever l or W be, if only the centre of gravity of the empty beam is brought to the proper distance from the central edge, we can give to the sensibility any value we please. What is actually done is so to construct the beam that its centre of gravity lies decidedly lower than one would ever care to have it, and then to connect with the beam a small movable weight (called the "bob") in such a manner that it can be shifted up and down along a wire, the axis of which coincides with the Y-axis, and thus the value s_0 of the distance of the centre of gravity of the beam from the central edge be caused to assume any value, from a certain maximum down to nothing, and even a little beyond nothing. As to the relative independence of the sensibility of the charge, equation 5 shows that a given balance will possess this quality in the higher a degree the less the distance h of the central edge is from the plane of the two terminal ones, and, supposing h to be constant (*i.e.*, the adjustment to be finished), the less the initial sensibility a_0 exhibited by the empty instrument. Passing from one balance to the other, but supposing h and a_0 to remain constant, we readily see that the sensibility is the more nearly independent of the charge p in the pans, the greater the *arm-length* l is. From what has been said above, it would appear that by means of a balance provided with a gravity-bob, we could attain any degree of precision we liked, but evidently this is not possible practically, because in the actual instrument neither the knife-edges and their bearings nor the arrestment are what we have hitherto supposed them to be; and, consequently, both l' and l'' as well as h, instead of being constants, are *variable quantities.* Obviously, the non-constancy of the ratio $l' : l''$ is the most important point, and to this point we shall therefore confine our attention. Let us imagine that the imaginary balance hitherto considered has been charged equally on both sides (with $P = p_0 + p$), so that its normal position is its position of rest, and then assume, first, that the *middle edge* (which hitherto has been an absolutely rigid line) is now a narrow and slightly, but irregularly, curved rough surface. The effect will be, that, supposing the balance to be repeatedly arrested and made to vibrate, the axis of rotation, instead of being constant, will shift irregularly between $x = +\lambda$ and $x = -\lambda$ where λ means a small length. But this comes to the same as if the central pivot *were* absolutely perfect, but had the common centre of gravity C_0, instead of being fixed at $x = 0$, oscillating between $x = \pm\lambda_0$. In other words, the balance may possibly come to rest at any position within a certain angle $\pm\beta$, which, as an angle of deviation, corresponds to the overweight

$$\epsilon_0 = \{2(p_0 + p) + W\}\frac{\lambda_0}{l}\,.$$

Assume now, secondly, that, say, the right terminal edge was slightly turned so as no longer to be parallel to the middle edge. This *in itself* would not matter much, because although it might produce a change in the length of the right arm, this change would be permanent, and the arm-length again be constant, provided the hook-and-eye arrangement for the suspension of the pan, and the arrestment, were ideally perfect. But, practically, they are *not*, and, moreover, the knife-edge and its bearing are not what theory supposes them to be; and the effect is the same as if the virtual point of application A of the charge $p_0 + p$, instead of being at the constant distance l from the centre, oscillated irregularly between $l + \lambda'$ and $l - \lambda'$, where λ' has a similar meaning to that of λ_0. The joint effect of the imperfections of the three pivots is that the indications of the balance, instead of being constant, are variable within $\pm\,\epsilon$, where ϵ means a small weight determined approximately by the equation—

$$\epsilon = \frac{1}{l}\{[2(p_0 + p) + W]\lambda_0 + 2(p_0 + p)\lambda\} \quad . \quad (7).—$$

Hence, in a balance to be constructed for a given purpose, l must be made long enough to make sure of its compensating the effects of the λ's, which, for a given set of knife-edges, and a given degree of absolute exactitude in their adjustment, may be assumed to have constant values. Evidently in a given balance ϵ has nothing to do with the sensibility, and consequently it would be useless to increase the sensibility beyond what is required to make the angle β, corresponding to ϵ (*i.e.*, that angle within which the balance is, so to speak, in indifferent equilibrium), *conveniently visible.* To go further would, in general, be a mistake, because the greater the sensibility the more markedly it varies with the charge, the less is the maximum overweight which can be determined by the method of vibration, and, last not least, the more slowly the balance will vibrate, because the time of vibration t is governed by the equation—

$$t = \sqrt{\frac{kW + 2(p_0 + p)}{Ws_0 + 2h(p_0 + p)}} \cdot \frac{l}{\sqrt{R_0}},$$

where k is a constant which depends on the shape of the beam, and for the ordinary perforated rhombus is about $= \frac{1}{3}$, while R_0 stands for the length of the pendulum beating seconds at the place. Introducing the sensibility—

$a = \dfrac{l}{Ws_0 + 2h(p_0 + p)}$, we have $t = c\sqrt{a}$, where c is a constant.

4. *Compound Lever Balances.*—Of these numerous inventions—in all of which a high degree of practical convenience is obtained at the expense of precision—we must content ourselves with noticing two which, on account of their extensive use, cannot be passed over. We here allude, in the first place, to that particular kind of equal-armed lever balances, in which the pans are situated above the beam, and which are known as "*Roberval's balances;*" and secondly, to those peculiar complex *steel-yards* which are used for the weighing of heavy loads by means of comparatively small weights.

In *Roberval's* balance (fig. 8), the beam consists of a parallelogram, in which each of the four corners A, B, A′, B′ is a joint, and which by means of two joints situated in the centres of the two longer sides AB and A′B′ is suspended from a vertical rod so that the two shorter sides AA′ and BB′ under all circumstances stand vertical. With these two sides the pans are rigidly connected; and the main feature in the machine is, that wherever the charge in the pan may lie, *i.e.*, whatever may be the virtual point of application of the whole charge P in regard to the vertical side of the beam, its statical effect is the same as if P was concentrated in a point D in the axis of the rod AA′ or BB′. That this really is so is easily proved. Imagine the particle weighing P units to be rigidly connected with, say, AA′, but situated to the left of that line, and, whatever may be its distance from AA′, when the beam descends through a certain angle, the vertical projection of the path described by the point D, *i.e.*, its fall h, has the same value whatever its distance from AA′. Hence the work done, say, against an elastic string tending to hold the beam in its place, invariably is $= Ph$, as it would be if D was situated in AA′.

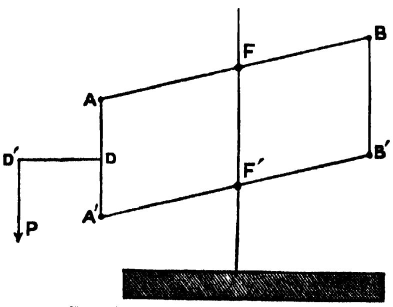

Fig. 8.—Roberval's Balance.

The ordinary *Decimal Balance* is a combination of levers illustrated by fig. 9. *a*, *c*, *b*, *d*, *e*, *g*, *h*, *f*, are all joints or pivots; *a* and *h* rest on the fixed framework of the machine, and consequently indirectly on the ground; *c* rests on the lever *ab*. In the actual machine *cd* supports the "*bridge*," which accommodates the load, while at *f* is suspended a pan for the weight. The pan is so adjusted

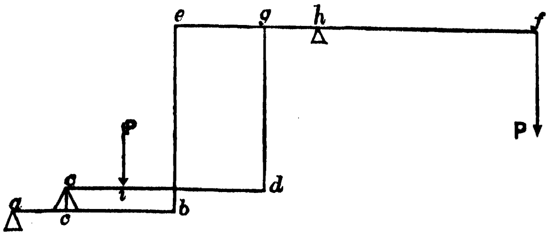

FIG. 9.—Decimal Balance.

that it balances the bridge. Suppose the load P to be placed so that its centre of gravity is at *i*, and a portion P_c of P will press on the knife-edge at *c*, the rest P_d will pull at *d* and, with the same force, at *g*. Now, $P_c = P.\frac{\overline{id}}{\overline{cd}}$, equivalent to $\frac{\overline{ac}}{\overline{ab}} P_c$ pulling at *b* or *e*, equivalent to $P.\frac{\overline{ac}}{\overline{ab}}.\frac{\overline{id}}{\overline{cd}}.\frac{\overline{eh}}{\overline{gh}}$ pulling at *g*. The dimensions are so chosen that $\frac{\overline{ac}}{\overline{ab}} = \frac{\overline{gh}}{\overline{eh}}$, hence the effect of P_c at *g* is equivalent to a weight $P.\frac{\overline{id}}{\overline{cd}}$. The other portion of P, viz., P_d, pulls at *d*, and consequently also at *g*, with a force $P.\frac{\overline{ic}}{\overline{cd}}$. Hence the effect of the total load is equivalent to $P.\left(\frac{\overline{ic}+\overline{id}}{\overline{cd}}\right) = P$ units suspended at *g*, and if, for instance, $gh = \frac{1}{10}\,hf$, one pound in the pan will counterpoise ten pounds at *any* point of the bridge.

5. *Torsion Balances.*—Of the several instruments bearing this name, the majority are no balances at all, but machines for measuring horizontal forces (electric, magnetic, &c.), by the extent to which they are able to distort an elastic wire vertically suspended and fixed at its upper end. In the torsion *balances* proper the wire is stretched out horizontally, and supports a beam so fixed to it that the wire passes through its centre of gravity. Hence the elasticity of the wire here plays the same part as the weight of the beam does in the common balance. An instrument of this sort was invented by Ritchie for the measurement of very small weights, and for this purpose it may offer certain advantages; but, clearly, if it were ever to be used for measuring larger weights, the beam would have to be supported by knife-edges and bearings, and in regard to such application therefore (*i.e.*, as a means for serious gravimetric work), it has no *raison d'être*. See ELECTRICITY and MAGNETISM.

6. For *Hydrostatic weighing-machines* see the article HYDROMETER. (W. D.)

BALANCE OF POWER. The theory of the Balance of Power may be said to have exercised a preponderating influence over the policy of European statesmen for more than two hundred years, that is, from the Treaty of Westphalia until the middle of the present century; and to have been the principal element in the political combinations, negotiations, and wars which marked that long and eventful period of modern history. It deserves, therefore, the attentive consideration of the historical student, and, indeed, the motive cause of many of the greatest occurrences would be unintelligible without a due estimate of its effects. Even down to our own times it has not been without an important influence; for the Crimean War of 1854 was undertaken by England and France for no other object than to maintain the balance of power in Eastern Europe, and to prevent the aggrandisement of Russia by the dismemberment of the Ottoman empire and the conquest of Constantinople. Nevertheless there is, perhaps, no principle of political science, long and universally accepted by the wisest statesmen, on which modern opinion has, within the last twenty years, undergone a greater change; and this change of opinion is not merely speculative, it has regulated and controlled the policy of the most powerful states, and of none more than of Great Britain, in her dealings with the continent of Europe. At the date of the publication of the last edition of this work, the theory of the balance of power was believed to be so firmly established, both by reason and experience, that it was laid down, in the forcible words of Earl Grey, that "the poorest peasant in England is interested in the balance of power, and that this country ought to interfere whenever that balance appeared to be really in danger." At the present time no English statesman would lay down that proposition categorically; and probably no European statesman would be prepared to act upon it. In proportion as the theory of the balance of power has lost much of its former authority, the doctrine of non-intervention has gained strength and influence, and this has been accepted at the present day both by Whig and Tory ministers, so that no strong difference of opinion can at the present time be said to exist in the British nation on the subject. Within the last fifteen years political changes of extraordinary magnitude have been brought about in Europe by force of arms and by revolutions. In former times such changes would certainly have led to a general war, on the principle that it was essential to maintain the relative strength and independence of states, and to support the fabric of European policy. But, under the policy of non-intervention, the effects of these contests have been confined to the states which were directly engaged in them; and the other powers of Europe have maintained a cautious neutrality, which has probably not lessened their own strength, and which has saved the world from a general conflagration.

The theory of the balance of power rested on several assumptions. It was held, more especially from the time of Grotius, in the early part of the 17th century, that the states of Europe formed one grand community or federal league, of which the fundamental principle and condition was the preservation of the balance of power; that by this balance (in the words of Vattel) was to be understood such a disposition of things, as that no one potentate or state shall be able absolutely to predominate and prescribe laws to the others; that all were equally interested in maintaining this common settlement, and that it was the interest, the right, and the duty of every power to interfere, even by force of arms, when any of the conditions of this settlement were infringed or assailed by any other member of the community. The principle can hardly be more tersely expressed than in the words of Polybius (lib. i. cap. 83): "Neque enim ejusmodi principia contemnere oportet, neque tanta cuiquam astruenda est potentia, ut cum eo postea de tuo quamvis manifesto jure disceptare ex æquo non queas." Or, to borrow the language of Fénelon in his *Instructions*, drawn up by him for the guidance of the Duc de Bourgogne, "This attention to maintain a sort of equality and equipoise between neighbouring nations is the security of the general tranquillity. In this respect all neighbouring nations, trading with each other, form one great body and a sort of community. Thus, Christendom is a kind of universal republic, which has its interests, its fears, and its precautions to be taken. All the members

of this great body owe it to one another for the common good, and owe it to themselves for the security of their country, to prevent the progress of any other members who should seek to overthrow this balance, which would turn to the certain ruin of all the other members of the same body. Whatever changes or affects this general system of Europe is too dangerous, and draws after it indefinite mischiefs." Whatever may be the value of these philanthropic principles, history reminds us that when they were most loudly professed they were most frequently violated, and that no cause of war seems to have been so frequent or so fatal as the spurious pretext of restoring peace and defending the general tranquillity of the world. Thus, it was to balance the power of the house of Austria that Cardinal Richelieu flung France into the quarrels of Germany in the Thirty Years' War, and even lent her aid to the Protestant cause. It was to balance the encroaching and aggressive power of Louis XIV. that numerous combinations were formed between England, Austria, and Holland, which, after nearly half a century of almost uninterrupted contests and bloodshed, ended in the peace of Utrecht. The pretext of Frederick II., when he was meditating some act of rapine, generally was that he believed some hostile combination had been formed against him, which it was wise to anticipate. In short, no cause of war has been more frequently alleged and acted upon, than that a proper consideration for the balance of power rendered it necessary to take forcible measures to avert some remote or hypothetical danger.

It is obviously a maxim, not only of policy but of common sense and human nature, that the weak should combine to protect themselves against the strong, and that when the independence of minor states is threatened by the ambition or the overwhelming superiority of a power aiming at universal empire, they will do wisely to unite for the purposes of self-defence and resistance. Frederick II. himself says, in his *Anti-Machiavel*, where he laid down precepts which he did not practise, "When the excessive aggrandisement of one power threatens to overwhelm all others, it is the part of wisdom to oppose barriers to its encroachments, whilst there is yet time to stay the torrent. The clouds are seen to gather, the lightning announces a coming storm, and the sovereign who is unable to contend against the tempest will, if he is wise, unite himself with all those who are menaced by the same common danger. Had the kings of Egypt, Syria, and Macedonia confederated together against the Roman power, they would not have fallen under its oppressive yoke; an alliance prudently contracted, and a war carried on with energy, would have saved the ancient world from universal despotism." So too, Hume, in his celebrated *Essay on the Balance of Power*, endeavours to show that the ancients were familiar with the principle both as statesmen and historians, and, for example, he avers that whoever will read Demosthenes's oration for the Megalopolitans, will see the utmost refinements on this principle that ever entered into the head of Venetian or European speculatist.

But with great respect to these illustrious authorities, they appear to have discussed, under the name of the balance of power, a principle which might more fitly be termed a theory of warlike alliances. The object of the balance of power, rightly understood, is not to carry on war with success, but to avoid war altogether, by establishing a common interest and obligation in the maintenance of the conditions of peace. When war is declared, public law is suspended, and each state must be guided by what it conceives to be its own interest and duty. If the theory of the balance of power has any value at all, it is not in the hour of violence and bloodshed, when the fate of nations may be decided on a field of battle, but rather in those negotiations which must eventually terminate the contest, which commonly bring together for that purpose the representatives of all the belligerents, and which are designed to provide against the recurrence of these calamities.

The ablest and most eloquent champion of the system of equipoise in the present century was the Chevalier von Gentz, who published his *Fragments upon the Balance of Power in Europe* in 1806, under the influence of the catastrophe which had subjugated the Continent, and who subsequently took an active part at the Congress of Vienna in the attempts to constitute a new system of European policy. Gentz defines the balance of power as "a constitution subsisting between neighbouring states more or less connected with one another, by virtue of which no one among them can injure the independence or essential rights of another, without meeting with effectual resistance on some side, and consequently exposing itself to danger." And he rests this constitution on four propositions:—(1.) That no state must ever become so powerful as to coerce all the rest; (2.) That every state which infringes the conditions is liable to be coerced by the others; (3.) That the fear of coercion should keep all within the bounds of moderation; and (4.) That a state having attained a degree of power to defy the union should be treated as a common enemy. He argues that by a strict adherence to these principles wars would be averted, excessive power restrained, and the independent existence of the humblest members of the confederacy secured. But, for the reasons we have previously assigned, it is a fallacy to suppose that even the civilised states of Europe have ever naturally formed a confederacy, or that their relations are governed by common rules of action, recognised alike by all of them. That theory supplies a very insecure basis for the balance of power and the maintenance of peace. The law of nations, not being imposed or sanctioned by any supreme and sovereign authority, is, in fact, reducible to the general laws of morality, which ought to regulate the dealings of mankind, except when it has been expressed and established in the form of a contract, binding on all the parties to that obligation. To determine the true character and limits of the balance of power, we must have recourse, not to vague general principles, but to positive law, framed in the shape of international contracts, which are termed treaties, and which have been sanctioned at different epochs of modern history by a congress of states. This historical treatment of the subject leads us to more tangible and solid ground; and it will be seen that on these occasions more especially attempts have been made to establish a balance of power in Europe upon the basis of general treaties; and that these attempts have been rewarded by considerable, though not by permanent, success in the 17th, 18th, and 19th centuries.

The first idea of a general congress, to put an end to the horrors of the Thirty Years' War, and to adjust the conflicting claims of rival creeds and hostile princes, appears to have originated with the emperor of Germany in 1640. The attempt to restore peace by the authority of the Germanic Diet had failed. It became necessary to have recourse to mediating powers, and after a protracted preliminary negotiation, the Congress of Münster or Westphalia opened on the 11th July 1643,—the Catholic and Protestant belligerents being represented on the one hand, and the mediating powers, France, Sweden, Venice, and the Pope, on the other. We do not propose in this place to follow the train of these complicated negotiations. It is enough for our present purpose to remark that the great treaty which resulted from them, and was signed on the 24th October 1648, became the basis of the public law of Europe, and the first official recognition of the existence of a European balance of power. The conditions established

in Germany left the Catholic, the Lutheran, and the Reformed Churches in possession of their respective independence, whilst they relieved the minor princes from their strict dependence on the empire; but, above all, they conferred on France and Sweden, as mediating powers, the right of intervention for the purpose of upholding the provisions of the treaty. In other words, the balance which had been established between the states of Central Europe was regulated by external weights, which could be brought to bear upon it. The result of this combination, due mainly to Cardinal Mazarin, was certainly injurious to the unity and independence of Germany, and it tended to aid the aggressive and dictatorial power of Louis XIV. Nevertheless, the fundamental principles of the treaty of Westphalia were recognised and renewed as the conditions of the general peace of Europe down to the French Revolution; they were not wholly absent from the minds of the negotiators at Vienna in 1815; and they only received their death-blow from the hand of the Prussian Government in 1866 and 1870. Whatever might be the merits of the Treaty of Westphalia, it had not that of securing to Europe an unbroken or durable peace; and even the territorial relations of France and Germany were altered within thirty years of that time by the conquest of Franche Comté and Alsace. But the wars of Louis XIV. were not general wars, until he engaged in the fatal attempt to place his grandson on the throne of Spain, and to unite the two crowns in the house of Bourbon. Efforts had been made, in view of the approaching extinction of the Spanish branch of the house of Austria, to preserve the balance of power by a timely partition of the vast dominions of the Spanish empire—a remarkable example of an attempt to prevent a formidable catastrophe by an equitable arrangement. But it may be doubted whether any arrangement in which so little account was taken of the wishes and traditions of nations could possibly have succeeded; and it unquestionably failed, because Louis XIV. did not hesitate to repudiate the treaties he had signed, and to avail himself of the last will and testament of Charles II., which had been extorted from the Spanish Court by his intrigues. That event raised again the whole question of the balance of power in Europe. It was received as a doctrine of political faith that the union of the French and Spanish crowns in one family must be fatal to the independence of all other states; that it would replace the Stuarts upon the throne of England, and establish the ascendency of France and the Catholic party over Europe. It was therefore resisted by a coalition, of which England, Austria, and Holland were the principal members. France was at length reduced to the lowest point of humiliation, and in 1709 peace might have been obtained on every point but one. Louis refused to turn his arms against his own grandson, and the war continued till 1715. Philip V. retained the Spanish crown, and the relations of all the European states were once more adjusted with legal nicety at Utrecht. Great pains were taken to provide, by a system of renunciations, against the possibility of the union of the crowns of France and Spain on the same head, because it was held that such a contingency would be fatal to the balance of power in Europe. But these precautions did not prevent the conclusion, at a later period, of the family compact between the two branches of the house of Bourbon, which was regarded as a lasting danger to other countries, and was opposed by the whole strength of Britain and the genius of Chatham. The peace of Utrecht was denounced by Parliament and detested by the nation as an inglorious termination of a glorious war, and its authors were consigned to obloquy and exile; but it secured the peace of Europe for thirty years; it reduced the power of France; and had it not been for the German dominions of the house of Hanover, it might have been still longer before England was drawn into another war.

Hitherto the political system of Europe had comprised little more than the states of France, Austria, Spain, Sweden, and Holland, with the occasional intervention of Great Britain, more for the defence of the interests of others than of her own. But the 18th century witnessed a total change in the politics of the world. A new empire, Russia, arose in the north, under the genius of Peter and of Catherine; the ambition and military skill of Frederick II. raised Prussia from a secondary member of the German empire to a powerful and independent kingdom; the colonial empires of Spain, France, and Britain had extended their territorial interests to the continents of Asia and America, and to the eastern and the western isles, insomuch that wars, begun in Europe, soon raged on the banks of the Ganges and the St Lawrence; and the declaration of independence of the United States of America called into being a new and powerful people of the future. The partition of Poland, which was commenced in 1772, marked a new era of aggressive revolutionary policy; it was a gross invasion of the principle of the balance of power, effected by three powers, jealous of their respective strength, but indifferent to the rights of an independent nation and to the opinion of Europe.[1] That lawless act was the prelude to more violent attacks on the sovereignty and nationality of many countries, for before the century closed the French Revolution, and the wars that followed it, crushed to atoms the ancient fabric of Europe. Whilst events of this magnitude were occurring in the world, it is obvious that the theory of the balance of power was entirely displaced and dislocated. New elements were at work over a far wider area; new sources of power and influence were opened of far more importance than those territorial and dynastic questions which occupied the statesmen of Münster and of Utrecht; ancient land-marks were swept away; minor states were annihilated; and the temporary domination of Napoleon over a great portion of the continent of Europe seemed to have overthrown the balance of power for ever. In those dark and evil days public writers like Gentz and Mackintosh still maintained the principle that peace could only be restored by a due recognition of the rights and independence of every nation, and England adhered inflexibly to the policy of combining the scattered elements of Europe against the common enemy. Half a dozen times over these coalitions failed; but they succeeded at last, and this country had the glory of playing no inconsiderable part in the restoration of the liberties of all other nations against foreign aggression. Great as were the cost and the burden of that tremendous war, we still hold that the prodigious power of France and the boundless ambition of Napoleon left us no honourable alternative but to pursue it; and, as Mr Fox himself discovered when he conducted the negotiations of 1806, it was impossible to conclude peace with France without basely surrendering the whole interests of Europe to universal oppression, and without exposing this country to be at last the victim of a power which had devoured all the rest. The principle of the balance of power, in the sense of mutual defence, was never asserted with greater energy than it was by this country in that struggle, and we do not regret it. "As long," says Bacon, "as men are men, and as long as reason is reason, a just fear will be a just cause of a preventive war; but

[1] It deserves to be noticed that down to the partition of Poland, no state, however small, had been extinguished, annihilated, and "annexed" in the continuous wars of the two previous centuries—down to the republics of Geneva and San Marino all retained their national existence. The wars of the French Revolution, and still more the wars of our own times, have swept a multitude of the minor states and dynasties from the map of Europe, and incorporated them in larger empires.

especially if it be part of the case that there be a nation that is manifestly detected to aspire to new acquests, then other states assuredly cannot be justly accused for not paying for the first blow, or for not adopting Polyphemus's courtesy, to be the last that shall be eaten up."—(*Speech concerning a War with Spain.*)

Upon the fall of Napoleon in 1814 it became the common interest, and the universal desire, of all the sovereigns and nations of Europe to restore peace upon a settled basis, to re-establish the authority of public law, to reinstate the rightful owners in the possessions and dominions they had been forcibly deprived of, to reduce the military establishments which weighed so heavily on the finances and on the population of Europe, and to create anew a balance of power between the states of Europe, by which the greatest of them might be restrained and the least of them protected. A secret article had been annexed to the Treaty of Paris, declaring that "the allied powers had agreed among themselves on the bases which were to be given to the future system of equilibrium;" though what the nature of that agreement and of those bases was, has never been made clearly apparent. But the matter was unquestionably referred to the congress then about to open at Vienna, where the most powerful sovereigns and the most distinguished ministers of all the European states met for the first time in council. That congress was certainly the most complete, and in its action the most important, assemblage of independent political powers and their representatives which ever took place in the world. Its decisions were not all of them just, or wise, or disinterested. The broad general principles of pacification which had been laid down were more than once traversed and thwarted by particular interests and ambitions. The theory of the rights of legitimate sovereigns over their subjects was carried to an extravagant point, pregnant with danger for the future. Genoa was transferred to Sardinia, Venice to Austria, Norway to Sweden, Poland to Russia, part of Saxony to Prussia, and the sacred hopes and pledges of freedom which had animated the nations in the contest were forgotten by the leading courts of Europe in the division of the spoil. But in spite of these shortcomings and abuses, we cannot concur with writers who, like Hardenberg, denounce the Congress of Vienna as an auction of nations and an orgy of kings. It was said that every one withdrew from the Congress of Vienna disappointed, no one having obtained as much as he expected; but if so, that would suggest the inference that the general interest of Europe prevailed over the pretensions of each particular state. From the point of view we are now considering, which is the restoration of the balance of power, it cannot be denied that the Treaties of Vienna secured forty years of peace to Europe. They stood the brunt of two fresh convulsions in France in 1830 and in 1848, and their main provisions, though modified with respect to the Low Countries in 1832, and abrogated in Italy by the campaign of 1859, were not seriously impaired until the dissolution of the Germanic body in 1866, and the Franco-German War of 1870. During the whole of this period the warlike ambition of France, and the disposition of Russia to overawe Central Europe, were successfully held in check. At Vienna itself, and during the congress, the struggle was close and sometimes doubtful. Russia was resolved to retain the whole of Poland, which she occupied with her armies, and Prussia claimed the whole of Saxony as a compensation for her share of the Polish provinces. To counteract this combination of Russia and Prussia, an alliance was signed on the 3d January 1815 between Austria, England, and France, which might have led to hostilities between those powers and their recent allies. Perhaps it was fortunate that the return of Napoleon from Elba broke up the congress, and reminded all the powers that union and mutual concessions were the first duties of those who had devoted themselves to the cause of law, order, and peace. It was a sign of the wisdom of the congress, and of its respect for sound principles, that although France was the vanquished power and the author of the calamities of Europe, she was treated at Vienna with as much consideration as any other state. Her ambassador, M. de Talleyrand, had his full weight in the congress; and no attempt was made in 1814 to curtail her ancient territorial possessions or to lower her rank in Europe. On the contrary, the just influence of France was recognised as an essential condition of the balance of power.

For the first time, then, by this general act of the Congress of Vienna, the territorial possessions and frontiers of the Continental states were defined in one document, to which all the Governments of Europe were parties; the constitution of the Germanic body was incorporated in the same instrument, and the neutrality and independence of the smallest cities and commonwealths were established and guaranteed. Every state in Europe had therefore an equal right and interest to invoke the authority of the treaty, and to claim the execution of all its conditions. A complete fabric of European polity, such as had never existed before, was thus literally established by mutual contract; and every infraction of it might justly be brought under the consideration of the high contracting parties, or might even have been the ground of a declaration of war. In several instances this controlling power was wisely and beneficially exercised, and more than one burning question was adjusted by the conferences which met from time to time, always on the basis of the treaties of 1815. This certainly was the nearest approach ever made to a practical balance of power; and we owe to it, as we have seen, a long period of mutual confidence, respect for public law, and peace, which contributed enormously to the progress, prosperity, and happiness of the world.

But there are darker shades to the picture. The comprehensive interest which every state was thus held to have acquired in maintaining the general settlement might be held, and was held, to justify a dangerous and mischievous degree of intervention in the internal affairs of every other country, and this right was too often exercised in a manner injurious to liberty and independence. The northern powers, not content with the terms of the general alliance and the Treaties of Vienna, proceeded to connect themselves more closely by the mystic ties of the Holy Alliance, which provided that they were to act together on all subjects, and to regard their interests as one and indivisible. The construction they put upon the system recently established in Europe was that it gave the allied powers a right to interfere, not only for the prevention of quarrels, aggressions, and war, but in the internal government of states, for the purpose of preventing changes which they chose to regard as injurious to their own security and eventually to the balance of power. At the congresses and conferences of Troppau, Carlsbad, Aix-la-Chapelle, and Verona, these doctrines were avowed and acted upon to their furthest extent, and under pretence of maintaining and defending the common interests of Europe, the popular movements and constitutional progress of Italy were crushed, a French army entered Spain in 1823 to restore the authority of Ferdinand VII. against the Cortes, and even the independence of the South American colonies was represented as a blow to the peace and security of Europe. The British Government had early perceived that the interpretation thus given to the theory of the balance of power, and to what was termed the federal system in Europe, was only another name for an intolerable oppression, and that the right of intervention in the internal affairs of other countries

was claimed and exercised under false and dangerous pretexts. The duke of Wellington, who represented this country at the Congress of Verona, under instructions framed by Lord Castlereagh, was the first to declare that England could be no party to such an application of the theory of the alliance, and that this country preferred isolation to any such system of combined policy. That was the germ of the modern doctrine of non-intervention. But as long as the Treaties of Vienna lasted, it was our duty and our right to endeavour to support their authority, and to vindicate the rights established by a compact to which this country was a party. We declined in 1852 to join with Prussia in enforcing the declaration made by the allied powers in 1815, which excluded any member of the family of Bonaparte from the throne of France; but we sought, in conjunction with France, to protest against the annihilation of the kingdom of Poland, the incorporation of Cracow, the admission of non-German provinces into the confederation, and the invasion of Schleswig; and we opposed the annexation of Savoy and Nice to France, but alone and without effect. The compact of Vienna was gradually set aside and violated in the course of years by those who were most interested in maintaining it; and when the Emperor Napoleon III. proposed, in 1863, a new congress for the purpose of revising and re-establishing the balance of power in Europe, under the name of an International Council, England refused to be a party to the negotiation, and rejected the scheme. Lord Russell replied, "There being no supreme authority in such an assembly to enforce the decision of the majority, the congress would probably separate, leaving many of its members on worse terms with each other than they had been before." This was the last attempt made to bring the authority of a congress, representing the collective authority of Europe, to bear on questions affecting the general peace. When this point was reached it was apparent that the whole theory of the confederated system in Europe had become, for a time at least, obsolete; that the treaties and mutual guarantees on which that system rested had lost their power; and that there was no controlling force to resist the ambitious or warlike designs of any state capable of giving effect to them. The Italian campaign of 1859 had considerably altered the condition of Southern Europe, and weakened Austria. Possibly, Prussia, in withholding her assistance at that time from her federal ally, foresaw in the defeat of Austria an event favourable to her own future pretensions. At any rate, for the first time, a war seriously affecting the balance of power was begun and ended by the two principal belligerents alone, and even the price paid by the house of Sardinia for the services of France—the cession of Savoy and Nice—was tacitly acquiesced in by Europe. Twenty years before, it would have been thought impossible that the doctrine of non-intervention should have acquired so great an ascendency.

But the consequences of this novel state of affairs soon became manifest in the increasing disintegration of Europe. No state could have a greater claim than Denmark to the protection of the principles of the balance of power, for, as late as 1852, all the great powers had pledged themselves by treaty to maintain the integrity of her dominions, the unity of the monarchy, and the order of succession to the crown which was then established. Yet in 1864 the German powers proceeded to what was termed a Federal Execution against her; Holstein, Lauenberg, and, eventually, Schleswig were torn from her by Prussia, Austria acting a subordinate part. England in vain appealed by her diplomacy to the terms of the agreement of 1852, but France and Russia stood aloof, and the greatest injustice the world had witnessed since the partition of Poland was consummated. As every event in political life is closely connected, Prussia now proceeded to ally herself with the crown of Italy against Austria, and to execute her grand design of the overthrow of the Germanic Confederation and the expulsion of Austria from that body, which had been regarded as the centre of gravity of the European system. As long as that body subsisted, war was impossible between its respective members, and France was incapable of attacking their united forces. The success of Prussia in the campaign of 1866 was rapid and complete, and Austria ceased to form a part of the Germanic Confederation. The power of Prussia was further increased by the military conventions, which gave her the absolute command over the armies of the minor German states. This was undoubtedly the severest blow which had yet been inflicted on the balance of power in Europe; and the Emperor Napoleon III., who had recently given vent to his dissatisfaction with the treaties of 1815, now found himself confronted by an enemy infinitely more powerful and dangerous. The results of Sadowa were as fatal to the influence and security of France as if she herself had lost a campaign. The French nation, however, failed to understand the magnitude of the danger, though they were irritated by the approach of it. War was, on more than one occasion, on the point of breaking out; and at length France plunged into it with a recklessness and incapacity only to be equalled by the tremendous calamities that war caused her to endure. Again, no third state was drawn by political considerations into the conflict. The terms of peace were settled between the vanquished and the conquerors without reference to the general interests of other nations; and no attempt has been made to place these arrangements under the sanction of the public law of Europe. Russia took advantage of the agitated condition of Western Europe to abrogate, by her own will and pleasure, an important stipulation of the Treaty of Peace of 1856, and Europe again submitted to this breach of covenant.

The general result is that, at the present time, the military power of the German empire far surpasses that of any other state, and could only be resisted by a general combination of all the rest. The balance of power, as it was understood fifty years ago, and down to a more recent time, has been totally destroyed; no alliances can be said to exist between any of the great powers, but each of them follows a distinct course of policy, free from any engagements to the rest, except on some isolated points; the minor states can appeal to no certain engagement or fixed general principle for protection, except, perhaps, as far as the neutrality of Switzerland and Belgium is concerned; and for the last two centuries there has not been a time at which all confidence in public engagements and common principles of international law has been so grievously shaken. Where the reign of law ends, the reign of force begins, and we trace the inevitable consequence of this dissolution of legal international ties in the enormous augmentation of military establishments, which is the curse and the disgrace of the present age. Every state appears to feel that its security depends on arming the whole virile population, and maintaining in what is called a state of peace all the burdens of a complete armament; indeed, in the most barbarous ages and the most sanguinary wars there were, doubtless, fewer men under arms, and less money was spent in arming them, than at the present day.

We have shown in the preceding observations that we do not retain the faith of our forefathers in the balance of power. It is impossible to equalise the strength of nations. It is impossible to regulate or control the growth and development of their forces, which depend not on territorial possessions alone, but on their industry, their credit, their natural resources, and their internal institutions. It is

impossible to weigh their relative power and influence in nice or golden scales, nor can we always compel them "parcere subjectis et debellare superbos." But the recognition of certain mutual obligations and principles of public law is the fundamental condition of civilisation itself. Nothing can be more injurious to society than that the states of Europe should exist without alliances, without mutual confidence, without a common system based on the principles of justice and of peace, the weak living in dread of the strong, the strong armed to the teeth against each other. We trust that before another great catastrophe arises from this state of disguised hostility, a truer balance of power may be established by a return to sounder principles; for peace can never be secure unless it is protected by the concurrence of the leading nations of the world, and by their determination to oppose a combined resistance to those who have no object but their own aggrandisement and ambition. (H. R.)

BALASOR, a district of British India in the Orissa division, under the Lieutenant-Governor of Bengal, lies between 20° and 21° N. lat., and in 86° and 87° E. long., and is bounded on the N. by the district of Midnapur; on the S. by Cattack district, from which it is separated by the Baitaraní river; on the W. by the tributary states of Keunjhar, Nílgiri, and Morbhanj; and on the E. by the Bay of Bengal. Balasor district forms a strip of alluvial land between the hills and the sea, varying from about 9 to 34 miles in breadth; area, 2066 sq. miles. The hill country rises from the western boundary line. The district naturally divides itself into three well-defined tracts—(1.) The Salt Tract, along the coast; (2.) The Arable Tract, or rice country; and (3.) The Submontane Tract, or jungle lands. The Salt Tract runs the whole way down the coast, and forms a desolate strip a few miles broad. Towards the beach it rises into sandy ridges, from 50 to 80 feet high, sloping inland, and covered with a vegetation of low scrub jungle. Sluggish brackish streams creep along between banks of fœtid black mud. The sand hills on the verge of the ocean are carpeted with creepers and the wild convolvulus. Inland, it spreads out into prairies of coarse long grass and scrub jungle, which harbour wild animals in plenty; but throughout this vast region there is scarcely a hamlet, and only patches of rice cultivation at long intervals. From any part of the Salt Tract one may see the boundary of the inner arable part of the district, fringed with long lines of trees, from which every morning the villagers drive their cattle out into the saliferous plains to graze. The Salt Tract is purely alluvial, and appears to be of recent date. Towards the coast the soil has a distinctly saline taste.

Salt is largely manufactured in this tract by evaporation. The following is the process followed:—At the beginning of December the contractor selects his locality, about a quarter to half a mile from the sea, and engages a class of men called *chuliyás*, or heads of salt gangs. These men receive 1s. a cwt. for whatever amount of salt they turn out. They, in their turn, engage working parties of *malangis*, who are paid at the rate of 3d. to 5d. a day. The ground is first marked out by a shallow trench, and the grasses and bushes are carefully dug up and removed. A deep ditch is next dug from the sea, by means of which, twice a month, the spring tides overflow the salt-field, and fill a number of reservoirs, 4 feet in diameter, and 2 or 3 feet deep. A mound of earth is then piled up to the height of 2 feet, and from 3 to 4 in diameter. It is next hollowed out into the shape of a bowl, plastered inside with clay, and furnished with a hole at the bottom, covered with a layer of grass 6 inches thick. The salt-makers fill this bowl with saline earth scraped off the adjacent land, and pour the sea-water on it from the top. By the end of six hours the water has drained through into a pit at the bottom, and runs down a thatched trench towards a reservoir, whence it is transferred to the evaporators. The latter consist of from 160 to 200 little unglazed earthenware pots, fastened together by stiff tenacious mud, and holding two quarts each. The neighbouring plains supply grasses for the fuel. Six hours' boiling completes the process. The brine, which consisted in the first place of sea-water charged to its maximum power of solution by percolating through the bowls of salt earth, subsides into dirty crystals at the bottom of the pots. It is then ladled out in spoons made of half cocoa-nuts. The whole process is as rude and careless as can well be imagined. The total cost of manufacture is estimated at 2s. 1d. a cwt., which with the Government duty of 8s. 8d., makes a total cost of 10s. 9d

The Arable Tract lies beyond the salt lands, and embraces the chief part of the district. It is a long dead level of rich fields, with a soil lighter in colour than that of Bengal or Behar; much more friable, and apt to split up into small cubes with a rectangular cleavage. A peculiar feature of the Arable Tract is the *Páts*, literally the Cups, or depressed lands near the river banks. They were probably marshes that have partially silted up by the yearly overflow of the streams. These Cup-lands bear the finest crops. As a whole, the Arable Tract is a treeless region, except around the villages, which are encircled by fine mango, *pipal*, banyan, and tamarind trees, and intersected with green shady lanes of bamboo. A few palmyras, date palms, and screw pines (a sort of aloe, whose leaves are armed with formidable triple rows of hook-shaped thorns) dot the expanse, or run in straight lines between the fields. The Submontane Tract is an undulating country with a red soil, much broken up into ravines along the foot of the hills. Masses of laterite, buried in hard ferruginous clay, crop up as rocks or slabs. At Kopári, in Kila Ambohatá, about 2 square miles are almost paved with such slabs, dark red in colour, perfectly flat, and polished like plates of iron. A thousand mountain torrents have scooped out for themselves picturesque ravines, clothed with an ever-fresh verdure of prickly thorns, stunted gnarled shrubs, and here and there a noble forest tree. Large tracts are covered with Sál jungle, which nowhere, however, attains to any great height.

Balasor district is watered by six distinct river systems: 1. The Subanrekhá, literally the streak of gold, forms the boundary between Balasor and Midnapur, flowing in a tortuous southern course, with gigantic bends from east to west till it reaches the sea in lat. 21° 35′ N. and long. 87° 23′ E. It is navigable by country craft as high as Kálíkápur, about 16 miles from the mouth, to which point the tide also runs. Rice boats of 2 tons' burden can make their way up to the end of the Balasor district, and during the rains far into the tributary state of Morbhanj. 2. The intermediate country on the south of the Subanrekhá and the north of the Burábalang, forms a great line of drainage down from Morbhanj. It is watered by a number of small streams, of which the principal are the Jamirá, Báns, and Bhairingí. They unite, bifurcate, and re-unite in the wildest confusion, and at length enter the sea as the Pánchpárá, in lat. 21° 31′ N. and long. 87° 10′ E. 3. South of this network of rivers is the Burábalang, literally the Old Twister. It rises among the Morbhanj hills, in lat. 21° 24′ and long. 86° 36′, and after receiving two small tributaries, the Gangáhar and Sunaí, wriggles into the sea in lat. 21° 28′ and long. 87° 5′. Brigs, sloops, and sea-going steamers can navigate this river as far as the town of Balasor, about 16 miles up its twisting course, but the sand-bar across the mouth of the river renders the entrance difficult. 4. South of the Burábalang, a network of rivers, known as the Jámká, find their way down the line of drainage from the western Nílgiri hills, and enter the sea by many channels. 5. The Kánsbáns, rising in Kila Ambohatá, runs in a south-easterly direction, at first almost parallel with the Nílgiri hills, and receives from them a number of nameless drainage streams on its northern bank. At Bírpárá it bifurcates, the northern branch retaining its original name, and entering the sea in lat. 21° 12′ 25″, long. 86° 52′ 10″. The southern branch receives the name of Gammaí, and falls into the sea 6 miles south of the Kánsbáns. This river is navigable only

a few miles up, but is celebrated for its sudden floods and the vast extent of country which it submerges in the rainy season. 6. The Baitaraní enters the district at the village of Balípur, and flows for about 45 miles in a south-westerly direction till it joins the Dhámrá, 5 miles from its mouth. The united stream enters the sea under the name of the Dhámrá, in lat. 20° 47′, long. 87°. The Dhámrá is a fine navigable estuary, but, like all the Orissa rivers, it is rendered perilous by a bar across its mouth.

Population of Balasor in 1872, 770,232 souls, residing in 3266 villages, and 138,913 houses; persons per square mile, 378; villages per square mile, 1·58; persons per village, 236; houses per square mile, 67; persons per house, 5·5. Of the total population 738,396, or 95·9 per cent., were Hindus; 18,878, or 2·4 per cent., Mahometans; 530, or ·1 per cent., Christians; 1 Buddhist; and 12,427, or 1·6 per cent., of aboriginal origin. The proportion of males to the total district population was 49·2 per cent.; number of male adult agriculturists, 150,391, and male adult non-agriculturists, 82,542. Bráhmans, Karans, Khandáits, and other castes, compose the Hindu population. There are two settlements of Christian missionaries in the district belonging to the Freewill Baptists, from Dover, New Hampshire, U.S. The district contains only one town with upwards of 5000 inhabitants, viz., Balasor itself, with 18,263. Almost the whole population of the district lives by agriculture. Rice forms the staple crop of the district, and is divided into 5 great *genera*, and 49 principal varieties. Pulses, oil-seeds, hemp, tobacco, cotton, sugar-cane, &c., make up the other agricultural products of Balasor. Balasor husbandmen consist of two classes, *thání* or cultivators, with a right of occupancy, and *páhí*, or tenants at will. Roughly speaking, one half of the district is under tillage, and the other half incapable of cultivation. Exports—Grain, sugar, oil-seeds, timber, hides, horns, &c. Imports—Native cloths, English piece-goods, &c. Total revenue of the Balasor district in 1870-71, £102,052, of which £41,408, or 40 per cent., was from land; total expenditure in the same year, £51,620. In 1872 the police force of the district consisted of 566 officers and men of the regular police, maintained at a total cost of £8879, 8s.; 32 officers and men of the municipal police, maintained at a cost of £224, 1[illegible].; and 2320 men of the village watch, maintained by grants of service lands and by subscriptions from villages, which amounted to £2745 in 1872; total strength of police, 2918 men; total cost, £11,849. Balasor contained 1053 schools in 1872, attended by 11,538 pupils. The Government and aided schools were 43 in number, attended by 1631 pupils, and maintained at a total cost of £1559, to which Government contributed £748, 16s. The climate of Balasor greatly varies according to the seasons of the year. The hot season lasts from March to June, but is tempered by cool sea breezes; from June to September the weather is close and oppressive; and from October to February the cold season brings the north-easterly winds, with cool mornings and evenings. (W. W. H.)

BALASOR, the principal town and administrative head-quarters of the above district, situated on the River Burábalang, in 21° 28′ 45″ N. lat., and 86° 59′ 33″ E. long., about 8 miles from the sea-coast as the crow flies, and 16 by the river. The English settlement of Balasor, formed in 1642, and that of Pippli in its neighbourhood, seven years earlier, became the basis of the future greatness of the British in India. The servants of the East India Company here fortified themselves in a strong position, and carried on a brisk investment in country goods, chiefly cottons and muslins. They flourished in spite of the oppressions of the Mahometan governors, and when needful asserted their claims to respect by arms. In 1688, affairs having come to a crisis, Captain Heath, commander of the Company's ships, bombarded the town. In the 18th century Balasor rapidly declined in importance, on account of a dangerous bar which formed across the mouth of the river. At present the bar has 12 to 15 feet of water at spring tides, but not more than 2 or 3 feet at low water in the dry season. Large ships have to anchor outside in the open roadstead. The town contains a population of 18,263; municipal income in 1872, £519; expenditure, £514; rate of taxation, 6¾d. per head of population. (W. W. H.)

BALBI, ADRIAN, one of the most eminent geographers of modern times, was born at Venice in 1782. In 1820 he visited Portugal, and there collected materials for his well-known work entitled *Essai Statistique sur le Royaume de Portugal et d'Algarve*, which was published at Paris in 1822. This was followed by *Variétés Politiques et Statistiques de la Monarchie Portugaise*, which contains some curious observations respecting that country under the Roman sway, and on the state of literature and the arts. In 1826 he published the first volume of his *Atlas Ethnographique du Globe*, &c., a work of great erudition, embodying the researches of the most distinguished German philologists and geographers. In 1832 appeared the *Abrégé de Géographie*, which added greatly to the author's reputation. This work, in an enlarged form, was translated into the principal languages of Europe. Balbi afterwards retired to Padua, where he continued to pursue his favourite science with unabated ardour. Besides those already mentioned, he was the author of several other works in the same department of science. He died on the 14th of March 1848.

BALBO, CESARE, an important Italian writer and statesman, was born at Turin, November 21, 1789. His father, Prospero Balbo, held a high position in the Piedmontese court, and at the time of Cesare's birth was syndic of the capital. His mother, a member of the Azeglio family, died when he was three years old; and he was brought up in the house of his great-grandmother, the countess of Bugino, "a noble and proud old lady." In 1798 he joined his father at Paris. From 1808 to 1814 Balbo served in various capacities under the Napoleonic empire, helping, at Florence and Rome, to fix the chains of despotism on his country. Gradually, however, his eyes were opened, and, on the fall of Napoleon, he was ready, in various capacities, to serve the cause of his country. While his father was appointed minister of the interior, he entered the army, and undertook political missions to Paris and London. On the revolution of 1821 he was forced into exile, and though, not long after, he was allowed to return to Piedmont, all active service as a statesman was denied him. Reluctantly, and with frequent endeavours to obtain some appointment, he gave himself up to literature as the only means left him to influence the destinies of his country. This accounts for the fitfulness and incompleteness of so much of his literary work, and for the practical, and in many cases temporary, element that runs through even his most elaborate productions. The great object of his labours was to help in securing for Italy that independence from foreign control which, even more than internal freedom, he regarded as the first necessity of national life. Of true Italian unity he had no expectation and no desire. A confederation of separate states under the supremacy of the Pope was the genuine *beau idéal* of Balbo, as it was the ostensible *beau idéal* of Gioberti. But Gioberti, in his *Primato*, seemed to him to neglect the first essential of independence, which he accordingly inculcated in his *Speranze* or *Hopes of Italy*. Preparation, both military and moral, alertness, and patience, were his constant theme. He did not wish revolution, but reform; and thus he became the leader of a moderate party, and the steady opponent not only of despotism but of democracy. At last, in 1848, his hopes were so far satisfied by the constitution granted by the king. He was appointed a member of the commission of electoral law, and held a post in the first reformed government. With the ministry of Azeglio, which soon after got into power, he continued on friendly terms, and his pen continued the active defence of his political principles till his death, on the 3d June 1853. The most important of his writings are historico-political, and derive at once their majesty and their weakness from his theocratic theory of Christianity. His style is clear and vigorous, and not unfrequently terse and epigrammatic. He published *Quattro Novelle* in 1829; *Storia d' Italia* in 1830; *Vita di Dante*, 1839; *Meditazioni Storiche*, 1842-5; *Le Speranze d' Italia*, 1843; *Sommario della Storia d' Italia*.

BALBOA, VASCO NUÑEZ DE, one of the bravest and most successful of the Spanish discoverers of America, was born at Xeres de los Caballeros, in Estremadura, about the

year 1475. He was by birth a *hidalgo*, or gentleman, but was in poor circumstances. Little is known of his life till the year 1501, when he was one of the company of adventurers who followed Roderigo de Bastidas in his voyage of discovery to the western seas. He appears to have settled in Hispaniola, and took to cultivating land in the neighbourhood of Salvatierra, but with no great success, as his debts soon became oppressive. In 1509 the famous Ojeda sailed from San Domingo with an expedition, and founded the settlement of San Sebastian. He had left orders with Enciso, an adventurous lawyer of the town, to fit out two ships and convey provisions to the new settlement. Enciso set sail in 1510, and Balboa, whose debts made the town unpleasant to him, managed to accompany him, by concealing himself in a cask which was conveyed from his farm to the ship as if containing provisions. The expedition, after various adventures, reached San Sebastian to find Ojeda gone and the settlement in ruins. While Enciso was undecided how to act, Vasco Nuñez proposed that they should sail for Darien, on the Gulf of Uraba, where he had touched when with Bastidas. His proposal was at once accepted, and carried out. The new town was named Sta Maria de la Antigua del Darien. Bitter quarrels soon broke out among the adventurers, caused chiefly by Enciso prohibiting all private interchange for gold with the natives. Enciso was deposed from the office of authority which he had assumed, but it was found no easy matter to elect a successor. Nicuesa, in whose province they were, was proposed by several, and was brought from Nombre de Dios by a ship which had been sent out to bring assistance to him. The inhabitants of Darien, however, would not receive him, and, in their wrath, seized him and placed him, with seventeen companions, in a crazy bark with which to find his way back to Hispaniola. The party of Vasco Nuñez grew strong; Enciso was thrown into prison, and finally sent off to Spain along with Vasco's ally, the alcalde Zamudio. Being thus left in authority, Balboa began to make excursions into the surrounding country, and by his bravery and conciliatory manners gained the friendship of several native chiefs. On one of these excursions he heard for the first time of the great ocean that lay on the other side of the mountains, and of the wondrous land of gold, afterwards called Peru. Soon after his return to Darien he received letters from Zamudio, informing him that Enciso had complained to the king, and had obtained a sentence condemning Balboa and summoning him to Spain. In his despair at this message Vasco resolved to attempt some great enterprise, the success of which he trusted would conciliate his sovereign. On the 1st September 1513, he set out with about 190 men, well armed, and sailed to Coyba, where he left half his forces to guard the canoes and ships. With the remainder he started on his perilous journey across the isthmus. On the 26th September they reached the summit of the range of mountains, and the glorious expanse of the Pacific was displayed to them. Three days later, they began to descend the mountains on the western side, and Vasco, arriving at the sea-shore, formally took possession of the ocean in the name of the Spanish monarch. He remained on the coast for some time, heard again of Peru, had the Pearl Islands pointed out to him, and set out for Darien. On the 18th January 1514 he reached the town, and was received with the utmost joy. He at once sent messengers to Spain bearing presents, to give an account of his discoveries; but, unfortunately, these did not arrive till an expedition had sailed from Spain, under Don Pedro Arias de Avila (generally called Pedrarias, or Davila), to replace Vasco Nuñez, and to take possession of the colony. For some time after Pedrarias reached Darien Vasco was in great straits, but at length letters came from the king, announcing to him his satisfaction with his exploits, and naming him *Adelantado*, or admiral. Pedrarias was prevailed upon to be reconciled with Vasco, and gave him one of his daughters in marriage. Vasco then resolved to accomplish his grand project of exploring the western sea. With infinite labour materials for building ships were conveyed across the isthmus, and two brigantines were constructed. With these the adventurers took possession of the Pearl Islands, and, had it not been for the weather, would have reached the coast of Peru. This career of discovery was stopped by the jealousy of Pedrarias, who feared that Balboa would throw off his allegiance, and who enticed him to Acla by a crafty message. As soon as he had him in his power, he threw him into prison, had him tried for treason, and forced the judge to condemn him to death. The sentence, to the grief of all the inhabitants, was carried into execution on the public square of Acla in 1517.

BALBRIGGAN, a seaport of Ireland, in the county of Dublin and parish of Balrothery, 18½ miles N.N.E. of the capital. The harbour, though dry at low tides, has a depth of 14 feet at high-water springs, and affords a good refuge from the E. or S.E. gales. It is formed by a pier 600 feet long, with a lighthouse at its extremity, in 53° 37′ N. lat., 6° 12′ W. long. A viaduct of eleven arches crosses the harbour. The town has considerable manufactures of cottons and hosiery, and is much frequented as a watering-place in summer. Population in 1871, 2332.

BALDE, Jakob, a modern Latin poet of considerable repute, was born at Ensisheim in Alsace in 1603, and died in 1668. He entered the Society of the Jesuits in 1624, and for the greater part of his life acted as court-preacher and professor of rhetoric at Munich. His Latin poems were very numerous, and those in imitation of Horace are particularly successful. Although Balde has received some attention since Herder translated several of his best pieces, and although some of his poems are by no means deficient in lightness, grace, and skilful versification, it would be a mistake to look upon him as a poet of high rank. A collected edition of his works in 4 vols. was published at Cologne in 1650; a more complete edition in 8 vols., at Munich, 1729. Extracts have been given by Orelli, 1805, 1818; and some detached poems have been published by various editors.

BALDI, Bernardino, a distinguished mathematician and miscellaneous writer, was descended of a noble family at Urbino, in which city he was born on the 6th of June 1533. He pursued his studies at Padua with extraordinary zeal and success, and is said to have acquired, during the course of his life, no fewer than sixteen languages, though according to Tiraboschi, the inscription on his tomb limits the number to twelve. The appearance of the plague at Padua obliged him to retire to his native city, whence he was, shortly afterwards, called to act as tutor to Ferrante Gonzaga, from whom he received the rich abbey of Guastalla. He held office as abbot for twenty-five years, and then retired to his native town. In 1612 he was employed by the duke as his envoy to Venice, where he distinguished himself by the congratulatory oration he delivered before the Venetian senate on the election of the new doge, Andrea Memmo. Baldi died at Urbino on the 12th of October 1617. He was, perhaps, the most universal genius of his age, and is said to have written upwards of a hundred different works, the chief part of which have remained unpublished. His various works give satisfactory evidence of his abilities as a theologian, mathematician, geographer, antiquary, historian, and poet. The *Cronica dei Matematici* is an abridgment of a larger work, on which he had bestowed twelve years of labour, and which was intended to contain the lives of more than two

hundred mathematicians. His life has been written by Affò, Mazzuchelli, and others.

BALDINGER, Ernest Gottfried, a German physician of considerable eminence, and the author of a great number of medical publications, was born near Erfurt, 13th May 1738. He studied medicine at Erfurt, Halle, and Jena, and in 1761 was intrusted with the superintendence of the military hospitals connected with the Prussian encampment near Torgau. He published, in 1765, a dissertation on the diseases of soldiers, which met with so favourable a reception that he published an enlarged edition, under the title of *Treatise on the Diseases that prevail in Armies*, Langensalza, 1774, 8vo. In 1768 he became professor of medicine at Jena, whence he removed, in 1773, to Göttingen, and in 1785 to Marburg, where he died of apoplexy on the 21st of January 1804. Among his pupils were Akermann, Sömmering, and Blumenbach. Some eighty-four separate treatises are mentioned as having proceeded from his pen, in addition to numerous papers scattered through various collections and journals.

BALDINUCCI, Filippo, a distinguished Italian writer on the history of the arts, was born at Florence about 1624, and died in 1696. His chief work is entitled *Notizie de Professori del Disegno da Cimabue in quà* (*dal* 1260 *sino al* 1670), and was first published, in six vols. 4to, 1681–1728. The capital defect of this work is the attempt to derive all Italian art from the schools of Florence. A good edition is that by Ranalli (5 vols. 8vo, Florence, 1845–47). Baldinucci's whole works have been published in fourteen vols. at Milan, 1808–12.

BALDOVINETTI, Alessio, was a distinguished painter of Florence in the 15th century, whose works have now become very scarce. Hogarth takes him as a type of those obscure artists to whom the affected amateurs of his time were wont to ascribe old paintings—"'Tis a fine piece of Alessio Baldovinetti, in his third manner." His father, Baldovinetti, belonged to a merchant family of good standing and fortune. Alessio was born in 1422, and took to painting, according to Vasari, against his father's desire. His art was distinguished rather for study than for genius. It represents completely some of the leading characters of the Florentine school in that age. It was an age of diligent schooling and experiment, in which art endeavoured to master more of the parts and details of nature than she had mastered heretofore, and to improve her technical means for their representation. Among the parts of nature especially studied in the 15th century, were landscape and natural history, the particulars of scenery, and the characters of birds, beasts, and plants. Alessio Baldovinetti surpassed all his contemporaries in attention to these matters. In Vasari's words, you see in his paintings "rivers, bridges, stones, grasses, fruits, roads, fields, cities, castles, arenas, and an infinity of suchlike things." From this quality of his art it has been guessed, without sufficient cause, that he was the pupil of Paolo Uccelli, the first Florentine master who devoted himself to such matters. For the rest, this extreme care and minuteness renders his manner somewhat hard. Like many other painters of his time, he treats draperies, hair, and such parts, with a manner that shows the influence of the goldsmith, and is more proper to metal work than to painting. His principal extant works are a nativity in the church of the Annunziati, an altar-piece, No. 24, in the gallery of the Uffizi, and another, No. 2, in the gallery of ancient pictures in the Academy of Arts at Florence. The great work of his life was a series of frescoes from the Old Testament in the chapel of the Gianfigliazzi family in the church of Sta Trinita, containing many interesting contemporary portraits; but these were destroyed about 1760. He also designed a likeness of Dante for the cathedral of Florence in 1465. His technical experiments were of the same nature as those made by his contemporaries—Pesellino, Pollaiuolo, and Domenico Veniziano, who endeavoured to find out an oil medium at Florence before Antonello da Messina had brought to Venice the secrets of the Flemish practice. Vasari relates how Alessio thought he had made a great discovery with the mixture of yolk of egg and heated *vernice liquida*, but how the work so painted presently became discoloured. He understood mosaic as well as painting, and between 1481 and 1484 was engaged in repairing ancient mosaics, first in the church of San Miniato, next in the baptistery at Florence. He is said to have instructed Dominico Ghirlandaio (see Bigordi) in this art. He died on the 29th of August 1499, within two years and a half of the completion of his frescoes in the Gianfigliazzi chapel. (Vasari, ed. Lemonnier, vol. iv. pp. 101–107; Crowe and Cavalcaselle, *Hist. of Painting in Italy*, vol. ii. pp. 372–381.) (s. c.)

BALDUINUS, Jacobus, a distinguished professor of civil law in the university of Bologna. He was by birth a Bolognese, and is reputed to have been of a noble family. He was a pupil of Azo, and the master of Odofredus, of Hostiensis, and of Jacobus de Ravanis, the last of whom has the reputation of having first applied dialectical forms to legal science. His great fame as a jurist caused him to be elected *podestà* of the city of Genoa, where he was intrusted with the reform of the laws of the republic. He died at Bologna in 1225, and has left behind him some treatises on Procedure, which have the merit of being the earliest of their kind.

BALDUR, one of the most interesting figures of the Scandinavian mythology, was the son of Odin and Frigg. His name (from *baldr*, the foremost or pre-eminent one) denoted his supreme excellence and beauty. In the *Gylfeginning* we read that he was so amiable that all loved him, so beautiful that a light seemed to shine about him, and his face and hair were for ever refulgent. He was the mildest, wisest, and most eloquent of the Æsir; and when he pronounced a judgment, it was infallible. His dwelling was in Brejdablik (far-sight), where nothing impure could come, and where the most obscure question could be explained. The wonderful legend of his death is first dimly recorded in the *Völuspa*, the grandest and most ancient of Eddaic poems, and more fully in the younger Edda. Baldur was visited by evil dreams, and felt his life to be in danger. His mother, Frigg, took oath of all things in the world, animal, vegetable, and mineral, that they should not slay her son. The gods being then secure, found pastime in setting the good Baldur in their midst, and in shooting or hurling stones at his invulnerable body. Then Loki, the evil god, took on him the form of a woman and went to Frigg in Fensal. From Frigg he learned that of all things in the earth but one could injure Baldur, and that was a little tree westward from Valhal, that was too young to take the oath. Thither went Loki and found the plant; it was the mistletoe. He plucked it up, fashioned it into an arrow, and went back to the Æsir. They were still in a circle, shooting at Baldur; and outside the ring stood the blind god Höder, of whom Loki asked wherefore he did not shoot. When Höder had excused himself because of his blindness, Loki offered to aim for him, and Höder, shooting the arrow of mistletoe, Baldur suddenly fell, pierced and dead. No such misfortune had ever yet befallen gods or men; there was long silence in heaven, and then with one accord there broke out a loud noise of weeping. The Æsir dared not revenge the deed, because the place was holy, but Frigg, rushing into their midst, besought them to send one to Hel to fetch him back. Hel promised to let him go if all things in heaven and earth were unanimous in wishing it to be so; but when inquiry was made, a creature called Thökt was found

in the cleft of a rock that said, "Let Hel keep its booty." This was Loki, and so Baldur came not back to Valhal. His death was revenged by his son Vale, who, being only one night old, slew Höder; but Loki fled from the revenge of the gods. In Baldur was personified the light of the sun; in his death the quenching of that light in winter. In his invulnerable body is expressed the incorporeal quality of light; what alone can wound it is mistletoe, the symbol of the depth of winter. It is noticeable that the Druids, when they cut down this plant with a golden sickle, did so to prevent it from wounding Baldur again. According to the *Völuspa*, Baldur will return, after Ragnarök, to the new heavens and the new earth; so the sun returns in spring to the renovated world. In the later versions it was no ordinary season, but the Fimbul winter, which no summer follows, which Baldur's death prefigured. It must not be overlooked that the story of Baldur is not merely a sun-myth, but a personification of that glory, purity, and innocence of the gods which was believed to have been lost at his death, thus made the central point of the whole drama of the great Scandinavian mythology. Baldur has been also considered, in relation to some statements of Saxo Grammaticus, to have been a god of peace, —peace attained through warfare; this theory has been advanced by Weinhold with much ingenuity. Several myths have been cited as paralleling the story of the death of Baldur; those of Adonis and of Persephone may be considered as the most plausible. (E. W. G.)

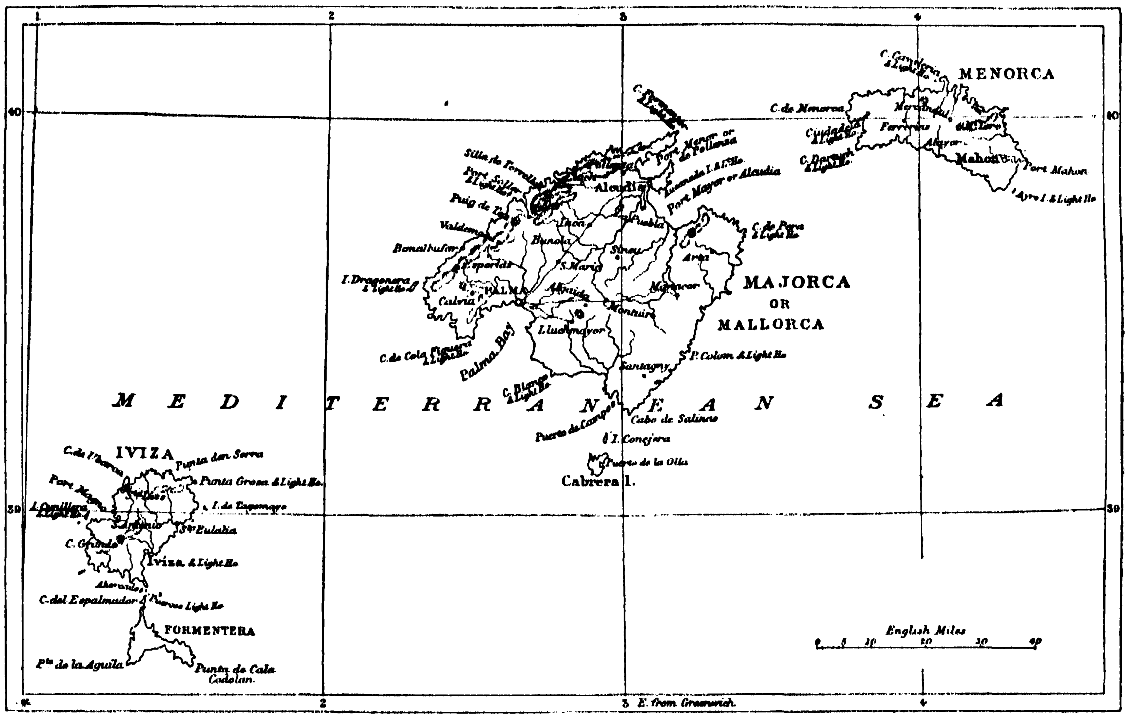
BALDUS, an eminent professor of the civil law, and also of the canon law, in the university of Perugia. He came of the noble family of the Ubaldi; and his two brothers, Angelus de Ubaldis and Petrus de Ubaldis, were almost of equal eminence with himself as jurists. He was born in 1327, and studied civil law under Bartolus at Perugia, where he was admitted to the degree of doctor of civil law at the early age of seventeen in 1344. Fredericus Petruccius of Siena is said to have been the master under whom he studied canon law. Upon his promotion to the doctorate he at once proceeded to Bologna, where he taught law for three years; after which he was advanced to a professorial chair at Perugia, which he occupied for thirty-three years. He taught law subsequently at Pisa, at Florence, at Padua, and at Pavia, at a time when the schools of law in those universities disputed the palm with the school of Bologna. Baldus has not left behind him any works which bear out the great reputation which he acquired amongst his contemporaries. This circumstance may be in some respects accounted for by the active part which he took in public affairs, and by the fame which he acquired by his consultations, of which five volumes have been published by Diplovataccius. Baldus was the master of Peter Beaufort, the nephew of Pope Clement VI., who became himself Pope under the title of Gregory XI., and whose immediate successor, Urban VI., summoned Baldus to Rome to assist him by his consultations against the anti-pope Clement VII. Cardinal de Zabarella and Paulus de Castro were also amongst his pupils. His *Commentary on the Liber Feudorum* is considered to be one of the best of his works, which have been unfortunately left by him for the most part in an incomplete state.

BALDWIN, THOMAS, a celebrated English prelate of the 12th century, was born of obscure parents at Exeter, where, in the early part of his life, he taught a grammar school. After this he took orders, and was made archdeacon of Exeter; but he resigned that dignity, and became a Cistercian monk in the monastery of Ford in Devonshire, of which, in a few years, he was made abbot. In the year 1180 he was consecrated bishop of Worcester. In 1184 he was promoted to the see of Canterbury, and by Urban III. was appointed legate for that diocese. He laid the foundation of a church and monastery in honour of Thomas à Becket at Hackington, near Canterbury, for secular priests; but being opposed by the monks of Canterbury and the Pope, he was obliged to desist. Baldwin then laid the foundation of the archiepiscopal palace at Lambeth. In 1189 he crowned King Richard I. at Westminster, and two years later, after making a pilgrimage through Wales to preach the Crusade, followed that prince to the Holy Land, where he died at the siege of Ptolemais or St Jean d'Acre. Giraldus Cambrensis, who accompanied him in an expedition through Wales, says he was of moderate habits and of an extremely mild disposition. He wrote various tracts on religious subjects, some of which were collected and published by Bertrand Tissier in 1662.

BALE, JOHN, Bishop of Ossory, in Ireland, was born at Cove, near Dunwich in Suffolk, in November 1495. He was educated in the monastery of the Carmelites at Norwich, and afterwards at Jesus College, Oxford. He belonged at first to the Roman Catholic Church, but was converted to the Protestant religion by Thomas Lord Wentworth. On the death of Lord Cromwell, the favourite of Henry VIII., who had protected him from the persecutions of the Romish clergy, he was obliged to take refuge in Flanders, where he continued eight years. Soon after the accession of Edward VI. he was recalled; and being first presented to the living of Bishop's Stocke (Bishopstoke), in Hampshire, he was nominated in 1552 to the see of Ossory, in Ireland. During his residence there he was remarkably assiduous in propagating the Protestant doctrines, but with little success, and frequently at the hazard of his life. On the accession of Queen Mary the tide of opposition became so powerful that, to avoid assassination, he embarked for Holland; and, after various vicissitudes, reached Basel in Switzerland, where he continued till the accession of Queen Elizabeth. After his return to England he was, in 1560, made prebendary of Canterbury, where he died in November 1563, in the sixty-eighth year of his age. Bale is noted as being one of the last (though not *the* last, as has sometimes been said) of those who wrote miracle-plays. Several of his are extant, and a list of titles of about twenty is given by Collier (ii. 238). They are remarkable for the determination they manifest to introduce and inculcate the doctrines of the Reformed religion. The best of his historical plays, *Kynge Johan*, has been published by the Camden Society, 1838. Of his numerous other works the most noted is his collection of British biography, entitled *Illustrium Majoris Britanniæ Scriptorum Catalogus, a Japheto sanctissimi Noah filio ad An. Dom.* 1559. This work was first published in quarto in 1548, and afterwards, with various additions, in folio, in 1557–59. Although slightly inaccurate, it is still a work of great value for the minute notices it gives of writers, concerning whom little is otherwise known. A selection from his works was published in 1849 by the Parker Society, containing the *Examinations* of Cobham, Thorpe, and Anne Askew, and the *Image of the two Churches*. Bale's style is frequently coarse and violent, and his truthfulness has been sometimes challenged.

BALEARIC ISLANDS, a remarkable group in the western part of the Mediterranean Sea, lying to the S. and E. of Spain, between 38° 40′ and 40° 5′ N. lat., and between 1° and 5° E. long. The name, as now employed, includes not only the ancient *Insulæ Baleares* (*Major* and *Minor*), but also the *Pityusæ* or Pine Islands, as the two more western were called. The origin of the name Baleares is a mere matter of conjecture, and the reader may choose any of the derivations usually offered with about an equal chance of not being right. On the other hand, it is obvious that the modern Majorca (or, in Spanish, Mallorca) and Minorca

(in Spanish, Menorca) are obtained from the Latin *Major* and *Minor*, through the Byzantine forms Μαιορικα and Μινορικα; while Iviza is plainly the older Ebusus, a name of, probably, Carthaginian origin. The *Ophiusa* of the Greeks (*Colubraria* of the Romans) is now known as Formentera.



Sketch-Map of the Balearic Islands.

Majorca. Majorca is the largest island of the group, having an area of 1430 square miles. Its shape is that of a trapezoid, with the angles directed to the cardinal points; and its diagonal, from Cape Grozer in the W. to Cape Pera in the E., is about sixty miles. On the N.W. the coast is highly precipitous, but on the other sides it is low and sloping. On the N.E. there are several considerable bays, of which the chief are those of Alcudia and Pollenza; while on the S.W. is the still more important bay of Palma. No fewer than twelve ports or harbours are enumerated round the island, of which may be mentioned Andraix, Soller, and Porto Colom. In the N.W. Majorca is traversed by a chain of mountains running parallel with the coast, and attaining its highest elevation in Silla de Torillas, 4600 feet above the sea. Towards the south and east the surface is comparatively level, though broken by isolated peaks of considerable height. The northern mountains afford great protection to the rest of the island from the violent gales to which it is exposed, and render the climate remarkably mild and pleasant, while the heats of summer are tempered by the sea-breezes. The scenery of Majorca is varied and beautiful, with all the picturesqueness of outline that usually belongs to a limestone formation. Some of the valleys, such as those of Valdemoza and Soller, with their luxuriant vegetation, are delightful resorts. There are quarries of marble, of various grains and colours—those of Santagny, in the partido of Manacor, being especially celebrated; while lead, iron, and cinnabar have also been obtained. Coal of a jet-like character is found at Benisalem, where works were commenced in 1836, at Selva, where it has been mined since 1851, near Santa Maria, and elsewhere. It is used in the industrial establishments of Palma, and in the manufacture of lime, plaster, and bricks, in the neighbourhood of the mines,—a considerable quantity being also exported to Barcelona. The inhabitants are principally devoted to agriculture, and most of the arable land of the islands is under cultivation. The mountains are terraced; and the old pine woods have in many places given place to the olive, the vine, and the almond tree, to fields of wheat and flax, or to orchards of figs and oranges. For the last-mentioned fruits the valley of Soller is one of the most important districts, the produce being largely transmitted to France, and realising about £25,000 per annum. The oil harvest is very considerable, and Inca is the centre of the oil district. The wines are light but excellent, especially the Muscadel and Montona. The agricultural methods of the islands are still somewhat primitive, but the introduction of machinery indicates improvement, as well as the drainage, by an English company, of a marsh and lake, 8000 acres in extent, near the town of Alcudia. During the summer there is often great scarcity of water; but, according to a system handed down by the Moors, the rains of autumn and winter are collected in enormous reservoirs, which contain sufficient water to last through the dry season; and on the payment of a certain rate, each landholder in turn has his fields flooded at certain intervals. Mules are used in the agriculture and traffic of the island. The cattle are small, but the sheep are large and well fleeced. Pigs are largely reared, and exported to Barcelona. There is abundance of poultry and of small game. A good deal of brandy is made and exported. Excellent woollen and linen cloths are woven. The silkworm is reared, and its produce manufactured; and canvas, rope, and cord are largely made, from both native and foreign materials. The average value of the imports of the island is £550,000, and the exports amount to rather more. The roads are excellent, the four principal being those from Alcudia, Manacor, Soller, and Andraix to the capital. A railway is in course of construction from Palma by Inca to Alcudia, and the stock is all held by Mallorquins. A telegraphic line passes from Palma to Valcenia, and there is regular steam communication with Barcelona and Alicante. A Majorcan bank has been established, and a credit association for the development of the resources of

the island. The people are industrious and hospitable, and pique themselves on their loyalty and orthodoxy. They are often but poorly educated, and their superstition is great; crime, however, is rare. Vaccination is common throughout the island, except in the cities,—the women often performing the operation themselves when medical assistance cannot be got. Castilian is spoken by the upper and commercial classes; the lower and agricultural employ a dialect resembling that of the Catalans, with whom, also, their general appearance and manners connect them. Besides the towns already mentioned, Lluchmayor and Campos are places of considerable size; and the castle of Belbez near Palma, which was the former residence of the kings, is worthy of notice. Population of the island, 204,000.

Minorca. Minorca, the second of the group in size, is situated 27 miles E.N.E. of Majorca. It has an area of 260 square miles, and extends about 35 miles in length. The coast is deeply indented, especially on the north, with numerous creeks and bays,—that of Port Mahon being one of the finest in the Mediterranean, if not the best of them all, as the couplet of Andrea Doria quaintly puts it—

> "Junio, Julio, Agosto, y puerto Mahon
> Los mejores puertos del Mediterraneo son"—

"June, July, August, and Port Mahon are the best harbours of the Mediterranean." The ports Addaya, Fornelle, Ciudadela, and Nitja may also be mentioned. The surface of the island is uneven, flat in the south and rising irregularly towards the centre, where the mountain El Toro—probably so called from the Arabic Tor, a height, though the natives have a legend of a *toro* or bull—has an altitude of 5250 feet. Owing to want of shelter from mountains, the climate is not so equable as that of Majorca, and the island is exposed in autumn and winter to the violence of the north winds. The soil of the island is of very unequal quality; that of the higher districts being light, fine, and fertile, and producing regular harvests without much labour or cultivation, while that of the plains is chalky, scanty, and alike unfit for pasture and the plough. Some of the valleys have a good alluvial soil; and where the hills have been terraced, they are cultivated to the summit. The wheat and barley raised in the island are sometimes sufficient for home consumption; there is rarely a surplus. The *Hedysarum coronarium*, or zulla, as it is called by the Spaniards, is largely cultivated for fodder. Wine, oil, potatoes, legumes, hemp, and flax are produced in moderate quantities; fruit of all kinds, including melons, pomegranates, figs, and almonds, is abundant. The moniato, or sweet potato, is grown and exported to Algeria. The caper plant is common throughout the island, growing on ruined walls. Horned cattle, sheep, goats, &c., are reared, and the island abounds with small game. Stone of various kinds is plentiful; a soft stone, easily quarried, and acquiring hardness by exposure, is used for building. In the district of Mercadal and in Mount Santa Agueda are found marbles and porphyries superior to those of Italy, and lime and slate are also abundant. Lead, copper, and iron might be worked were it not for the scarcity of fuel. There are manufactures of the wool, hemp, and flax of the island; and formerly there was a good deal of boat-building; but, with the exception of agriculture, all branches of industry are comparatively neglected. The principal exports are wheat, cattle, cotton-stuffs, and shoes. An excellent road, constructed in 1713–15 by Brigadier Kane, to whose memory a monument was erected at the first milestone, runs through the island from S.E. to N.W., and connects Port Mahon with Ciudadela, passing by Alayor, Mercadal, and Ferrerias. Ciudadela, which was the capital of the island till Mahon was raised to that position by the English during their occupancy of the island, still possesses considerable remains of its former importance. Population of the island, 39,000.

Iviça. Iviça, Iviza, or, in Spanish, Ibiza, the *Ebusus* of the ancients, lies 50 miles S.W. of Majorca, and about 60 from Cape San Martin on the coast of Spain, between 38° 50′ and 39° 8′ N. lat., and between 1° 14′ and 1° 38′ E. long. Its greatest length from N.E. to S.W. is about 25 miles, and its greatest breadth about 13. The coast is indented by numerous small bays, the principal of which are those of San Antonio on the N.W., and of Iviza on the S.E coast. Of all the Balearic group, Iviza is the most varied in its scenery and the most fruitful. The hilly parts are richly wooded. It was on one of the summits called Campsey that one of the stations in the celebrated measurement of an arc of the meridian was placed. The climate is for the most part mild and agreeable, though the hot winds from the African coast are sometimes troublesome. Oil, corn, and fruits (of which the most important are the common fig, the prickly pear, the almond, and the carob-bean) are the principal productions of the island; but the inhabitants are rather indolent, and their modes of culture are very primitive. Hemp and flax are also grown. There are numerous salt-pans along the coast, which were formerly worked by the Spanish Government, but are now in the hands of a joint-stock company. Carob-beans, almonds, charcoal, and lead are the other articles of export, to which may be added stockings of native manufacture. The imports are rice, flour, and sugar, woollen goods, and cotton. The capital of the island, and, indeed, the only town of much importance,—for the population is remarkably scattered,—is Iviza or La Ciudad, a fortified town on the S.E. coast, consisting of a lower and upper portion, and possessing a good harbour. The population of the island is about 21,000, of whom 5500 are resident in the capital.

Formentera. South of Iviza lies the smaller and more irregular island of Formentera, which is said to derive its name from the production of wheat. It is situated between 1° 22′ and 1° 37′ E. long. With Iviza it agrees both in general appearance and in the character of its productions, but it is altogether destitute of streams. Goats and sheep are found in the mountains, and the coasts are greatly frequented by flamingoes. The last station in the measurement of the arc of the meridian was in this island.

Smaller islands. There are several smaller islands in the Balearic group, such as Cabrera, or Goat Island, and Conejera, or Rabbit Island, south of Majorca, but none of them are of any size or importance except Cabrera, which is full of caverns, and is used as a place of banishment. In 1808 it was the scene of a deed of gross barbarity—a large number of Frenchmen being landed on the island, and almost allowed to perish for want of food.

History. Of the origin of the early inhabitants of the Balearic Islands nothing is certainly known, though Greek and Roman writers refer to Bœotian and Rhodian settlements. According to general tradition the natives, from whatever quarter derived, were a strange and savage people till they received some tincture of civilisation from the Carthaginians, who early took possession of the islands, and built themselves cities on their coasts. Of these cities, Mahon, the most important, still retains the name which it derived from the family of Mago. About twenty-three years after the destruction of Carthage the Romans accused the people of the islands of piracy, and sent against them Q. Cæcilius Metellus, who soon reduced them to obedience, settled amongst them 3000 Roman and Spanish colonists, founded the cities of Palma and Pollentia, and introduced the cultivation of the olive. Besides valuable contingents of the celebrated Balearic slingers the Romans derived from their new conquest mules (from Minorca), edible snails, *sinope*, and pitch. Of their occupation numerous traces still exist,—the most remarkable being the aqueduct at Pollentia.

In 423 A.D. the islands were taken possession of by the Vandals, and in 798 by the Moors. They became a separate Moorish kingdom in 1009, which, becoming extremely obnoxious for piracy, was the object of a crusade directed against it by Pope Pascal II., in

which the Catalans took the lead. This expedition was frustrated at the time, but was resumed by Don Jaime, king of Aragon, and the Moors expelled in 1232. During their occupation the island was populous and productive, and an active commerce was carried on with Spain and Africa. Don Jaime conferred the sovereignty of the isles on his third son, under whom and his successors they formed an independent kingdom up to 1349, from which time their history merges in that of Spain. In 1521 an insurrection of the peasantry against the nobility, whom they massacred, took place in Majorca, and was not suppressed without much bloodshed. In the war of the Spanish Succession all the islands declared for Charles; the duke of Anjou had no footing anywhere save in the citadel of Mahon. Minorca was reduced by Count Villars in 1707; but it was not till June 1715 that Majorca was subjugated, and meanwhile Port Mahon was captured by the English under General Stanhope in 1708. In 1713 the island was secured to them by the peace of Utrecht; but in 1756 it was invaded by a force of 12,000 French, who, after defeating the unfortunate Admiral Byng, captured Port Mahon. Restored to England in 1769 by the peace of Versailles the island remained in our possession till 1782, when it was retaken by the Spaniards. Again seized by the English in 1798, it was finally ceded to Spain by the peace of Amiens in 1803. When the French invaded Spain in 1808, the Mallorquins did not remain indifferent; the governor, D. Juan Miguel de Vives, announced, amid universal acclamation, his resolution to adhere to Ferdinand VII. At first the Junta would take no active part in the war, retaining the corps of volunteers that were formed for the defence of the island; but finding it quite secure, they transferred a succession of them to the Peninsula to reinforce the allies. Such was the animosity excited against the French when their excesses were known to the Mallorquins, that some of the French prisoners, conducted thither in 1810, had to be transferred with all speed to the island of Cabrera, a transference which was not effected before some of them had been killed.

Armstrong's *Hist. of Minorca*, 1756; Dameto's *Hist. del reyno Balearico o de Mallorca; Hist. of Balearic Islands*, London, 1716; Vincente Mut's *Historia; Cleghorn's Diseases of Minorca*, 1751; Wernsdorf, *Antiquitates Balearicæ;* Clayton's *Sunny South*, 1869; George Sand, in *Revue des Deux Mondes*, 1841; D'Hermilly, *Hist. du Royaume de Minorque*, Maestricht, 1777; "Balearic Islands," in Bates's *Illustrated Travels*, vol. i.; *Die Balearen in Wort und Bild geschildert*, Leipsic, 1871; "Klima der Balearen" in the *Zeit. der Oesterr. Gesell. für Meteorologie*, 1874; Juan Ramis, *Antiguedades Celticas de la Isla de Menorca*, Mahon, 1818; Pauli, "Ein Monat auf den Balearen" in *Das Ausland*, 1873; Arago, *De ma jeunesse, Œuvres*, vol. i.; Biot, *Recueil d'Observations géodésiques*, &c., 1821.

BALES, PETER, a famous caligraphist, and one of the first inventors of short-hand writing. He was born in 1547, and is described by Anthony Wood as a "most dexterous person in his profession, to the great wonder of scholars and others." We are also informed that "he spent several years in sciences among Oxonians, particularly, as it seems, in Gloucester Hall; but that study, which he used for a diversion only, proved at length an employment of profit." He is mentioned for his skill in micrography in Hollingshed's *Chronicle*, anno 1575. "Hadrian Junius," says Evelyn, "speaking as a miracle of somebody who wrote the Apostles' Creed and the beginning of St John's Gospel within the compass of a farthing: what would he have said of our famous Peter Bales, who, in the year 1575, wrote the Lord's Prayer, the Creed, Decalogue, with two short prayers in Latin, his own name, motto, day of the month, year of the Lord, and reign of the queen, to whom he presented it at Hampton Court, all of it written within the circle of a single penny, inchased in a ring and borders of gold, and covered with a crystal so accurately wrought as to be very plainly legible; to the great admiration of her majesty, the whole privy council, and several ambassadors then at court?" Bales was likewise very dexterous in imitating handwritings, and about 1576 was employed by Secretary Walsingham in certain political manœuvres. We find him at the head of a school near the Old Bailey, London, in 1590, in which year he published his *Writing Schoolmaster, in three Parts*. In 1595 he had a great trial of skill with one Daniel Johnson, for a golden pen of £20 value, and won it; and a contemporary author further relates that he had also the arms of caligraphy given him, which are azure, a pen or. Bales died about the year 1610.

BALFE, MICHAEL WILLIAM, was born, in 1808, at Limerick in Ireland. His musical gifts became apparent at an early age. The only instruction he received was from his father, and a musician of the name of Horn; and it seems to have been limited to a superficial training of the voice, and to some lessons on the pianoforte. At one time Balfe also practised the violin, and was even bold enough to play in public one of Viotti's concertos, but, seemingly, without much success. He never seems to have studied systematically the fundamental principles of his art, and this want of rudimentary training has left the stamp of imperfection on all his works. Being in possession of a small but pleasant barytone voice, he chose the career of an operatic singer, and made his *début* in *Der Freischütz*, at Drury Lane, at the early age of sixteen. The following year he was taken to Rome by a wealthy family. In Italy he wrote his first dramatic work, a ballet, *Perouse*, first performed at the Scala theatre, Milan, in 1826. In the later part of the same year he appeared as Figaro in Rossini's *Barbiere*, at the Italian Opera in Paris, at that time the scene of the unequalled vocal feats of such singers as Sontag, Malibran, Lablache, and others. Balfe's voice and training were little adapted to compete with such artists; he soon returned to Italy, where, during the next nine years, he remained singing at various theatres, and composing a number of operas, now utterly and justly forgotten. During this time he married the prima donna, Mdlle. Luisa Roser, a lady of German birth, for whom one of his operas was written. He even made bold to disfigure, by interpolated music of his own, the works of Rossini, Donizetti, and other masters of established reputation. Fétis says that the public indignation, roused by an attempt at "improving" in this manner the opera *Il Crociato* by Meyerbeer, compelled Balfe to throw up his engagement at the theatre La Fenice in Venice. He returned to England, where, in 1835, his *Siege of Rochelle* was produced, and rapturously received at Drury Lane. Encouraged by his success, he produced a series of operas which for some time made him the most popular composer of the day. Amongst the works written for London we mention *Amelia, or the Love-test* (1838); *Falstaff* (with the incomparable Lablache as Sir John); *Keolanthe;* and the *Bohemian Girl* (1844). The last-mentioned work is generally considered to be his *chef d'œuvre;* it carried its composer's name to Germany, where it was performed with considerable success at various theatres. Balfe in the meantime also wrote several operas for the Opéra Comique and Grand Opéra in Paris, of which we may mention those called *Le Puits l'Amour, Les quatre Fils Aymon*, and *L'étoile de Seville*. After a short period of success his popularity began to decline, and at the time of his death in 1870, most of his music had become antiquated. A posthumous work of his, *The Talisman*, the libretto of which is taken from Walter Scott's novel, was performed at the Italian Opera, Drury Lane, in 1874, with considerable success. The chief charm of his works consists in a certain easy, not to say trivial, melodiousness, such as may be readily accounted for by the composer's Irish nationality without the addition of individual genius of a higher kind. He had also a certain instinct for brilliant orchestration, and for the coarser effects of operatic writing. Musical knowledge of a higher kind he never possessed, nor did he supply this want by the natural impulses of a truly refined nature. "To speak of Balfe as an artist is either to misuse the word or to permit its meaning to depend on temporary success, no matter how acquired." Such is the stern but not unjust verdict of the late Mr H. F. Chorley, whose opinion of the detrimental effect of Balfe's success "on the chances of establishing a real national opera" also appears to be correct. Balfe's claim to particular notice rests,

indeed, less on the intrinsic merits of his works than on their undoubted success; and, most of all, on the fact of his being one of the few composers of British birth whose names are known beyond the limits of their own country. (F. H.)

BALFOUR, SIR JAMES, of Pittendreich, at one time lord president of the Supreme Court in Scotland, an active and unscrupulous politician during the stormy period of the reign of Mary. He was originally educated for the church, and adopted the principles of the Reformers. With Knox and others he was condemned to the galleys on account of the part he had taken in the murder of Beaton, but after their release he abjured Protestantism, and speedily acquired great favour with the court, obtaining some considerable legal dignities. He was deeply implicated in the murder of Darnley, and drew up the bond which was signed by all the conspirators. As some reward for his services, he was made, by Mary, governor of Edinburgh Castle, a position in which he had a good opportunity for the exercise of his great talents for treachery. He yielded the castle to Murray on conditions favourable to himself alone, and then threw in his lot with the regent's party, by whose favour he secured the post of lord president. During the next few years he changed his political views more than once, but managed to keep in safety, though for a time he deemed it prudent to withdraw to France. On the accession of James he returned; and, after having had once to flee from Morton, now his deadly enemy, he brought about the destruction of that nobleman by producing the bond bearing upon Darnley's murder. He died not long after in 1583. The collection of statutes entitled the *Practicks* is generally ascribed to him; but it is not known how much of the book belongs to him and how much to Sir John Skene, his colleague in the task of arranging them.

BALFOUR, SIR JAMES, Bart., of Dennylne and Kinnaird, an eminent annalist and antiquary, was born about 1600. He received a good education, travelled for some time on the Continent, and then devoted his attention almost entirely to the study of the history and antiquities of his country. He was well acquainted with Sir Wm. Segar and with Dugdale, to whose *Monasticon* he contributed. He was knighted by Charles I. in 1630, was made lyon king-at-arms in the same year, and in 1633 received the baronetcy of Kinnaird. He was removed from his office of king-at-arms by Cromwell, and died in 1657. Some of his works, which are very numerous, are preserved in the Advocates' Library at Edinburgh, together with his correspondence,—from which rich collection Mr Haig published *Balfour's Annales of Scotland from the zeire* 1057–1603, in 4 vols. 8vo (1824–25). See Sibbald, *Memoria Balfouriana*, 1699.

BALFOUR, ROBERT, a learned Scotchman, born about the year 1550, who was for many years principal of the Guienne College at Bordeaux. His principal work is his *Commentary on the Logic and Ethics of Aristotle* (Burdig. 1616–20, 2 tom. 4to), which is described by Dr Irving (*Lives of the Scottish Writers*) as uniting vigour of intellect with great extent and variety of learning. Balfour was one of the scholars who in the Middle Ages contributed to spread abroad over the Continent the fame of the *perfervidum ingenium Scotorum*.

BALFROOSH, or BARFURÛSH, a large commercial town of Persia, province of Mazanderan, on the River Bhawal, which is here crossed by a bridge of nine arches, about twelve miles distant from the southern shore of the Caspian Sea, where the small town of Meshed-i-Sir serves as a kind of port. Built in a low and swampy, though fertile country, and approached by deep and almost impassable roads, it would not seem at all favourably situated for the seat of an extensive inland trade. It is, however, peopled entirely by merchants, mechanics, and their dependants, and is wholly indebted for its present size and importance to its commercial prosperity. The principal articles of its trade are rice, silk, and cotton. The town is of a very peculiar structure and aspect. It is placed in the midst of a forest of tall trees, by which the buildings are so separated from one another, and so concealed, that, except in the bazaars, it has no appearance of a populous town. The streets are broad and neat, though generally unpaved; and they are kept in good order. No ruins are to be seen, as in other Persian towns; the houses are comfortable, in good repair, roofed with tiles, and enclosed by substantial walls. There are no public buildings of any importance. The only places of interest are the bazaars, which extend fully a mile in length, and consist of substantially-built ranges of shops, covered with a roof of wood and tiles, and well stored with commodities. There are about ten principal caravansaries, and from twenty to thirty medresses or colleges, the place being as much celebrated for learning as for commerce. At the time of Fraser's visit (1822) it was said to contain 200,000 inhabitants, but this was probably an exaggeration. Since that time its population has undergone various fluctuations, and is now estimated at 125,000. Long. 52° 42′ E., lat. 36° 37′ N.

BALGUY, JOHN, an eminent English theologian and moral philosopher, was born at Sheffield on August 12, 1686. He received his early education partly under his father, and partly under Mr Daubuz, his father's successor, in the grammar-school of that town. He entered St John's College, Cambridge, in 1702, graduated Bachelor of Arts in 1706, was ordained to the ministry in 1710, and soon after obtained the small living of Lamesly and Tanfield in the county of Durham. He married in 1715. It was the year in which Bishop Hoadley preached that famous sermon on *The Kingdom of Christ*, which gave rise to the long, wearisome, and confused theological war known as the "Bangorian controversy;" and Balguy, under the *nom de plume* of Silvius, began his career of authorship by taking the side of Hoadley in this controversy against some of his High Church opponents. In 1726 he published *A Letter to a Deist concerning the Beauty and Excellency of Moral Virtue, and the support and improvement which it receives from the Christian Religion*, chiefly designed to show that, while a love of virtue for its own sake is the highest principle of morality, religious rewards and punishments are most valuable, and in some cases absolutely indispensable, as sanctions of conduct. He supposed that a contrary opinion had been maintained by Lord Shaftesbury in his *Inquiry concerning Virtue;* but an examination of that essay will prove him to have in this respect done Shaftesbury injustice. In 1728 he was made a prebend of Salisbury by his friend, Bishop Hoadley. He published in the same year the first part of a tractate entitled *The Foundation of Moral Goodness*, and in the following year a second part, "illustrating and enforcing the principles contained in the former." The aim of the work is twofold—to refute the theory of Hutcheson regarding the basis of rectitude, and to establish the theory of Clarke. His objections to Hutcheson's theory are,—(1.) That it represents virtue as arbitrary and insecure by making it depend on two instincts, benevolent affection and the moral sense; (2.) That if true, brutes, since they have kind instincts or affections, must have some degree of virtue; (3.) That if such affections constitute virtue, the virtue must be the greater in proportion as the affections are stronger, contrary to the notion of virtue, which is the control of the affections; and (4.) That virtue is degraded by being made a result of instincts instead of being represented as the highest part of our nature. Clarke's fundamental ethical principle, that virtue is conformity to

reason,—the acting according to fitnesses which arise out of the eternal and immutable relations of agents to objects,—is the central and guiding thought in Balguy's moral speculations, and even the source of what is most distinctive in his theology. His exposition of it is characterised by insight into its significance, and by ingenuity in disposing of the objections which had been urged against it. In 1729 he became vicar of Northallerton, in the county of York. His next work was an essay on *Divine Rectitude; or, a Brief Inquiry concerning the Moral Perfections of the Deity, particularly in respect of Creation and Providence.* It is an attempt to show that the same moral principle which ought to direct human life may be perceived to underlie the works and ways of God: goodness in the Deity not being a mere disposition to benevolence, but a regard to an order, beauty, and harmony, which are not merely relative to our faculties and capacities, but real and absolute; claiming for their own sakes the reverence of all intelligent beings, and alone answering to the perfection of the divine ideas. It is only, Balguy thinks, when the divine rectitude is thus viewed as aiming at order no less than at happiness, as acting according to the true reasons of things no less than from the affection of benevolence, that such facts as the gift of freedom to man, the introduction and infliction of natural evil, the inequalities of human fortune, the sufferings of the righteous, and the prosperity of the wicked, can be satisfactorily explained. There followed *A Second Letter to a Deist, concerning a late book entitled "Christianity as old as the Creation," more particularly that chapter which relates to Dr Clarke.* Here Balguy argues that Tindal had falsely inferred revelation to be superfluous from the perfection of the law of nature and the ability of reason to discover that law. He grants that the law of nature is perfect and unchangeable, and that men can know whatever it is their duty to do, but maintains that the light of reason may have, and has had, added to it by revelation knowledge of great interest and value. This, he holds, is all that Clarke had maintained, and Tindal had failed to show that he had fallen into any self-contradictions. The same leading thoughts which we find in the tracts just mentioned meet us again in *The Law of Truth, or the Obligations of Reason essential to all Religion.* In this essay it is contended,—(1.) That reason binds or obliges, in the strictest sense of the word, all moral agents; (2.) That, considering men in their intellectual and moral capacity, the obligations of religion are entirely founded on the obligations of reason; and (3.) That on this ground, religion, whether natural or revealed, stands very firm and secure. Balguy collected these tracts and published them in a single volume in 1734, the *Letter to a Deist* and the *Foundation of Moral Goodness* having previously passed through three editions. In 1741 he published an *Essay on Redemption*, containing somewhat peculiar views. Redemption as taught in Scripture means, according to him, "the deliverance or release of mankind from the power and punishment of sin, by the meritorious sufferings of Jesus Christ," but involves no *translation of guilt, substitution of persons,* or *vicarious punishment.* Freed from these ideas, which have arisen from interpreting literally expressions which are properly figurative, the doctrine, he argues, satisfies deep and urgent human wants, and is in perfect consistence and agreement with reason and rectitude. His last publication was a volume of sermons, pervaded by good sense and good feeling, and clear, natural, and direct in style, but bearing few traces of the influence of the most distinctive and potent Christian motives. He died at Harrowgate, September 21, 1748. A second volume of sermons appeared shortly afterwards. The edition of his sermons most commonly met with is the 3d, in 2 vols., published in 1760. The notice of his life in the *Biographia Britannica* was written by his son. See also Hunt's *Religious Thought in England*, vol. ii. 362–4, 454–6, iii. 87–9. Mr Hunt erroneously represents Shaftesbury and not Hutcheson as the philosopher assailed in the *Foundation of Moral Goodness.* (R. F.)

BALI, or LITTLE JAVA, one of the Sunda Islands, in the Eastern Seas, separated from Java by the straits of the same name, which are a mile and a half wide. It is 75 miles in length; its greatest breadth is 50 miles. A chain of mountains crosses the island in a direction E. and W., and terminates on the E. in the volcanic peak Gunung-agung, 12,379 feet above the sea-level. The climate and soil are the same as in Java; it has mountains of proportionate height, several lakes of great depth, and streams well fitted for the purposes of irrigation. Rice is produced in great quantities, and is even exported to Madura, Celebes, Timor, and Java. The other productions are tobacco, maize, pulses, oil, and salt; also cotton of an excellent quality. Coffee is now grown with great success; in the district of Teja Kulo alone, 150,000 trees were planted in the first four months of 1873. The inhabitants (estimated at about 800,000), though originally sprung from the same stock as those of Java, exceed them in stature and muscular power, as well as in activity and enterprising habits. "They have," says Sir Stamford Raffles, "a higher cast of spirit, independence, and manliness than belongs to any of their neighbours." They are good agriculturists and skilful artisans, especially in textile fabrics and the manufacture of arms. The imports are iron and cotton cloths, and opium to a great extent; in the district of Tabanan alone, forty chests of this drug are annually consumed. Both imports and exports are on the increase; but trade is chiefly in the hands of Europeans, Chinese, and Arabs, who have their firms or agents in Batavia, Surabaya, Makassar, and Singapore. The trade returns in the port of Padang Cove are estimated at £500,000 to £600,000 per annum; those of Buleleng and Jembrana were about £500,000 in 1873. The island is divided into the eight independent principalities of Buleleng, Karang Asam, Bangli, Tabanan, Mengui, Klong-kong, Gyanyar, and Badong, each under its own ruler. The deputy-commissioner of Banyuwangi in east Java is also charged with the superintendence of the island of Bali in behalf of the Dutch Government. Though native rule is described as very tyrannical and arbitrary, especially in the principalities of Badong and Tabanan, trade and industry could not flourish if insecurity of persons and property existed to any great extent. The natives have also a remedy against the aggression of their rulers in their own hands; it is called *Metilas*, consists in a general rising and renunciation of allegiance, and proves mostly successful. Justice is administered from a written civil and criminal code. Slavery is abolished. Hinduism, which was once the religion of Java, but has been extinct there for four centuries, is still in vogue in the islands of Bali and Lombok, where the cruel custom of widow burning is still practised, and the Hindu system of the four castes, with a fifth or Pariah caste (called *Chandâla*), adhered to. It appears partly blended with Buddhism, partly overgrown with a belief in *Kalas*, or evil spirits. To appease these, offerings are made to them either direct or through the mediation of the *Devas* (domestic or agrarian deities); and if these avail not, the *Menyepi*, or Great Sacrifice, is resorted to. Buddhism prevails only in three districts. The Mahometan religion is said to be on the wane, in spite of the good influence it has exerted upon the people. Of the early history of their island the Balinese know nothing. The oldest tradition they possess refers to a time shortly after the overthrow of the Majapahit dynasty in Java, about the middle of the 15th century; but, according to Lassen, who identifies Bali with the island visited by

Jambulos, there must have been Indian settlers there before the middle of the 1st century, by whom the present name, probably cognate with the Sanskrit *balin*, strong, was in all likelihood imposed. It was not till 1633 that the Dutch attempted to enter into alliance with the native princes, and their earliest permanent settlement at Port Badong only dates from 1845. Their influence was extended by the results of the war which they waged with the natives about 1847–9. A geological survey of the whole island is at present (1874–5) in progress under their auspices. The Balinese language belongs to the same group of the Malayan class as the Javanese, Sundanese, Madurese, &c., but is as distinct from each of these as French is from Italian. It is most nearly akin to the Sasak language spoken in Lombok and on the east coast of Bali. The literary language has embodied many of its ingredients from the Old Javanese, as spoken in Java at the time of the fall of Majapahit (15th century), while the vulgar dialect has kept free from such admixture. Javanese influence is also traceable in the use of three varieties of speech, as in the Javanese language, according to the rank of the people addressed. The alphabet is with some modifications the same as the Javanese, but more complicated. The material universally used for writing on is the prepared leaf of the lontar palm. The sacred literature of the Balinese is written in the ancient Javanese or *Kawi* language, which appears to be better understood here than it is in Java. (See R. van Eck, *Beknopte handleiding bij de beoefening van het Balineesche taal*, Utrecht, 1874.) In the years 1871 and 1872, 15,000 people died of small-pox in the island; since then vaccination has been introduced by the Dutch. In September 1874 several districts were fearfully ravaged by cholera; in Sampidi alone out of its 3000 inhabitants 700 fell victims to the scourge; the rest fled into the woods.

BALIOL, or BALLIOL, SIR JOHN DE, an English baron, after whom Balliol College in Oxford has been named, was the son of Hugh Baliol, of Bernard's Castle, in the diocese of Durham. His great wealth and power raised him to a prominent position in the kingdom, and he rendered good service to Henry III. in his contest with De Montfort and the revolted barons. In 1263 he endowed several scholarships at Oxford, and formed the intention of founding a college. This he did not accomplish, but after his death in 1269, his widow, Devorgille or Devorguill, carried out his design, and the foundation received the name of Balliol College. Sir John's son was the well-known John Baliol, the competitor with Bruce for the throne of Scotland.

BALKAN (the ancient *Hæmus*), a mountain range that separates the waters of the Lower Danube from those that flow into the Archipelago; or, in the more extended application of the name, the whole mountain system from the Adriatic to the Euxine. The main chain has a mean elevation of 4000 or 5000 feet, and rises in various parts to a height of 7000 or 8000. Especially towards the east it breaks up into a number of parallel chains, and sends out various offshoots both south and north. Mount Scardus, the highest point of the Char-Dagh, attains to 9700 feet above the sea. The most of the rivers of the northern watershed find their way to the Black Sea, while those from the southern fall into the Mediterranean. The range is crossed by numerous defiles, most of which are left in a nearly impassable condition, though they might in many cases be turned into serviceable routes. Communication is kept up between Vienna and Constantinople by the pass usually known as Trajan's Gate. Others of importance are the Nadir-Derbent, the Karnabad, and the Basardshik-Sophia. The mountains are for the most part of granitic formation, and are said to contain a variety of valuable minerals, but are still imperfectly known, in spite of the labours of Pouqueville, Boué, Viquesnel, Grisebach, Hahn, Barth, &c. Kanitz, between 1870 and 1874, crossed the eastern part no fewer than seventeen times by different passes.

See *Journey across Balkan by the Passes of Selimno and Pravadi*, London, 1831; Jochinus's "Journey," 1847, in *Journ. Roy. Geog. Soc.*, 1854; *Nouvelles Annales des Voyages*, 2d series, vol. x.; Petermann's *Mittheil.*, 1873–74.

BALKH, the ancient *Bactra* or *Zariaspa*, was formerly a great city, but is now for the most part a mass of ruins, situated on the right bank of the Adirsiah or Balkh river, in a large and fertile plain 1800 feet above the sea. The modern name is, according to Vámbéry, the Turkish *balik*, or *balikh*, a city. The ruins, which occupy a space of about twenty miles in circuit, consist chiefly of fallen mosques and decayed buildings of sun-burnt brick. No monuments of pre-Mahometan date have been pointed out, if we except the bricks with cuneiform inscriptions which Ferrier asserts he observed; but nothing like a proper investigation of the site has yet been effected. The antiquity and greatness of the place are recognised by the native populations, who speak of it as the *Mother of Cities*. Its foundation is mythically ascribed to Kaiomurs, the Persian Romulus; and it is at least certain that, at a very early date, it was the rival of Ecbatana, Nineveh, and Babylon. For a long time the city and country was the central seat of the Zoroastrian religion, the founder of which is said to have died within the walls. From the *Memoirs of Hwen Thsang*, a Chinese traveller, we learn that, at the time of his visit in the 7th century, there were in the city, or its vicinity, about a hundred Buddhist convents, with 3000 devotees, and that there was a large number of *stupas*, and other religious monuments. The most remarkable was the *Nau Behar*, *Nava Bihara*, or New Convent, which possessed a very costly statue of Buddha. A curious notice of this building is found in the Arabian geographer Yâkût. Ibn-Haukal, an Arabian traveller of the 10th century, describes Balkh as built of clay, with ramparts and six gates, and extending half a parasang. He also mentions a castle and a mosque. El Edrisi, in the 12th century, speaks of its possessing a variety of educational establishments, and carrying on an active trade. There were several important commercial routes from the city, stretching as far east as India and China. In 1220 Genghis Khan sacked Balkh, butchered its inhabitants, and levelled all the buildings capable of defence,—treatment to which it was again subjected in the 14th century by Timur. Notwithstanding this, however, Marco Polo can still, in the following century, describe it as "a noble city and a great." Balkh formed the government of Aurungzebe in his youth. In 1736 it was conquered by Nadir Shah. Under the Durani monarchy it fell into the hands of the Afghans; it was conquered by Shah Murad of Kunduz in 1820, and for some time has been subject to the Khan of Bokhara.

See *Houen Thsang*, tr. by Julien, vol. i. pp. 29–32; Burnes's *Travels in Bokhara*, 1831–33; Ferrier's *Travels*; Vambery's *Bokhara*, 1873.

BALL, JOHN, a Puritan divine, of whom Baxter speaks in very high terms, was born, in 1585, at Cassington, or Chessington, near Woodstock, and died in 1640. He entered Brazenose College, Oxford, in 1602, and remained there five years. He then migrated to St Mary's Hall, from which he took his bachelor's degree in 1608. Soon after graduating he went into Cheshire to act as tutor to

the children of Lady Cholmondeley. While there he was thrown into the company of some enthusiastic Puritans, whose views he quickly adopted. He resolved upon entering the church, and, going up to London, obtained ordination from an Irish bishop. He was afterwards appointed to the small curacy of Whitmore, near Stoke, in Staffordshire, and here he passed the remainder of his life, eking out his miserable stipend by teaching a small school. The most popular of his numerous works was the *Short Treatise, containing all the Principal Grounds of Christian Religion*, which has passed through a great many editions, and has been in common use as a Puritan catechism. His *Treatise of Faith* and *Friendly Trial of the Grounds tending to Separation*, the latter of which defines his position with regard to the church, are also valuable works.

BALLADS. The word ballad is derived from the Old French *baller*, to dance, and originally meant a song sung to the rhythmic movement of a dancing chorus. Later, the word became the technical term for a particular form of old-fashioned French poetry, remarkable for its involved and recurring rhymes. "Laisse moi aux Jeux Floraux de Toulouse toutes ces vieux poésies Françoises comme *ballades*," says Joachim du Bellay in 1550; and Philaminte, the lady pedant of Molière's *Femmes Scavantes*, observes—

"La ballade, à mon goût, est une chose fade,
Ce n'en est plus la mode, elle sent son vieux temps."

In England the term has usually been applied to any simple tale, told in simple verse, though attempts have been made to confine it to the subject of this paper, namely, Popular Songs. By popular songs we understand what the Germans call *Volks-lieder*, that is, songs composed by the people, for the people, handed down by oral tradition, and in style, taste, and even incident, common to the people in all European countries. The beauty of these purely popular ballads, their directness and freshness, has made them admired even by the artificial critics of the most artificial periods in literature. Thus Sir Philip Sydney confesses that the ballad of *Chevy Chase*, when chanted by "a blind crowder," stirred his blood like the sound of trumpet. Addison devoted two articles in the *Spectator* to a critique of the same poem. Montaigne praised the *naïveté* of the village carols; and Malherbe preferred a rustic *chansonette* to all the poems of Ronsard. These, however, are rare instances of the taste for popular poetry, and though the Danish ballads were collected and printed in the middle of the 16th century, and some Scotch collections date from the beginning of the 18th, it was not till the publication of Allan Ramsay's *Evergreen* and *Tea Table Miscellany*, and of Bishop Percy's *Reliques*, that a serious effort was made to recover Scotch and English folk-songs from the recitation of the old people who still knew them by heart. At the time when Percy was editing the *Reliques*, Madame de Chénier, the mother of the celebrated French poet of that name, composed an essay on the ballads of her native land, modern Greece; and later, Herder and Grimm and Goethe, in Germany, did for the songs of their country what Scott did for those of Liddesdale and the Forest. It was fortunate, perhaps, for poetry, though unlucky for the scientific study of the ballads, that they were mainly regarded from the literary point of view. The influence of their artless melody and straightforward diction may be felt in the lyrics of Goethe and of Coleridge, of Wordsworth, of Heine, and of André Chénier. Chénier, in the most affected age even of French poetry, translated some of the Romaic ballads; one, as it chanced, being identical with that which Shakspeare borrowed from some English reciter, and put into the mouth of the mad Ophelia. The beauty of the ballads and the interest they excited led to numerous forgeries. It is probable that Hogg was as great a culprit in Scotland as Prosper Mérimée with his *Guzla*, or collection of Servian imitations, in France. Editors could not resist the temptation to interpolate, to restore, and to improve the fragments that came in their way. The Marquis de la Villemarqué, who first drew attention to the ballads of Brittany, is not wholly free from this fault. Thus a very general scepticism was awakened, and when questions came to be asked as to the date and authorship of the Scottish traditional ballads, it is scarcely to be wondered at that Dr Chambers attributed most of them to the accomplished Lady Wardlaw, who lived in the middle of the 18th century.

The vexed and dull controversy as to the origin of Scottish folk-songs was due to ignorance of the comparative method, and of the ballad literature of Europe in general. The result of the discussion was to leave a vague impression that our native ballads were perhaps as old as the time of Dunbar, and were the production of a class of professional minstrels. These minstrels are a stumbling-block in the way of the student of the growth of ballads. The domestic annals of Scotland show that her kings used to keep court-bards, and also that strollers, *jongleurs*, as they were called, went about singing at the doors of farm-houses and in the streets of towns. Here were two sets of minstrels who had apparently left no poetry; and, on the other side, there was a number of ballads that claimed no author. It was the easiest and most satisfactory inference that the courtly minstrels made the verses, which the wandering crowders imitated or corrupted. But this theory fails to account, among other things, for the universal sameness of tone, of incident, of legend, of primitive poetical formulæ, which the Scotch ballad possesses, in common with the ballads of Greece, of France, of Provence, of Portugal, of Denmark, and of Italy. The object, therefore, of this article is to prove that what has long been acknowledged of nursery tales, of what the Germans call *Märchen*, namely, that they are the immemorial inheritance at least of all European peoples, is true also of ballads. The main incidents and plots of the fairy tales of Celts, and Germans, and Slavonic and Indian peoples, their unknown antiquity and mysterious origin, are universally recognised. No one any longer attributes them to this or that author, or to this or that date. The attempt to find date or author for a genuine popular song is as futile as a similar search in the case of a *Märchen*. It is to be asked, then, whether what is confessedly true of folk-tales,—of such stories as the *Sleeping Beauty* and *Cinderella*,—is true also of folk-songs. Are they, or have they been, as universally sung as the fairy tales have been narrated? Do they, too, bear traces of the survival of primitive creeds and primitive forms of consciousness and of imagination? Are they, like *Märchen*, for the most part little influenced by the higher religions, Christian or polytheistic? Do they turn, as *Märchen* do, on the same incidents, repeat the same stories, employ the same machinery of talking birds and beasts? Lastly, are any specimens of ballad literature capable of being traced back to extreme antiquity? It appears that all these questions may be answered in the affirmative; that the great age and universal diffusion of the ballad may be proved; and that its birth, from the lips and heart of the people, may be contrasted with the origin of an artistic poetry in the demand of an aristocracy for a separate epic literature, destined to be its own possession, and to be the first development of a poetry of personality,—a record of *individual* passions and emotions. After bringing forward examples of the identity of features in European ballad poetry, we shall proceed to show that they all sprang from the same primitive custom of dance, accompanied by improvised song, which still exists in Greece and Russia, and even in valleys of the Pyrenees.

There can scarcely be a better guide in the examination

of the *notes* or marks of popular poetry than the instructions which M. Ampère gave to the committee appointed in 1852–53 to search for the remains of ballads in France. M. Ampère bade the collectors look for the following characteristics:—"The use of assonance in place of rhyme, the brusque character of the recital, the textual repetition, as in Homer, of the speeches of the persons, the constant use of certain numbers,—as three and seven,—and the representation of the commonest objects of every-day life as being made of gold and silver." M. Ampère might have added that French ballads would probably employ a "bird-chorus," the use of talking-birds as messengers; that they would repeat the plots current in other countries, and display the same non-Christian idea of death and of the future world, the same ghostly superstitions and stories of metamorphosis, and the same belief in elves and fairies, as are found in the ballads of Greece, of Provence, of Brittany, Denmark, and Scotland. We shall now examine these supposed common notes of all genuine popular song, supplying a few out of the many instances of curious identity. As to brusqueness of recital, and the use of assonance instead of rhyme, as well as the aid to memory given by reproducing speeches verbally, these are almost unavoidable in all simple poetry preserved by oral tradition. In the matter of recurring numbers, we have the eternal—

"Trois belles filles
L'y en a'z une plus belle que le jour,"

who appear in old French ballads, as well as the "Three Sailors," whose adventures are related in the Lithuanian and Provençal originals of Mr Thackeray's *Little Billee*. Then there is "the league, the league, the league, but barely three," of Scotch ballads; and the τριὰ πουλακιά, three golden birds, which sing the prelude to Greek folk-songs, and so on. A more curious note of primitive poetry is the lavish and reckless use of gold and silver. M. Tozer, in his account of ballads in the *Highlands of Turkey*, remarks on this fact, and attributes it to Eastern influences. But the horses' shoes of silver, the knives of fine gold, the talking "birds with gold on their wings," as in Aristophanes, are common to all folk-song. Everything almost is gold in the *Kalevala*, an epic formed by putting into juxtaposition all the popular songs of Finland. Gold is used as freely in the ballads, real or spurious, which M. Verkovitch has had collected in the wilds of Mount Rhodope. The captain in the French song is as lavish in his treatment of his runaway bride,—

"Son amant l'habille,
Tout en or et argent";

and the rustic in a song from Poitou talks of his *faucille d'or*, just as a variant of Hugh of Lincoln introduces gold chairs and tables. Again, when the lover, in a ballad common to France and to Scotland, cuts the winding sheet from about his living bride—"il tira ses ciseaux d'or fin." If the horses of the Klephts in Romaic ballads are gold shod, the steed in *Willie's Lady* is no less splendidly accoutred,—

"Silver shod before,
And gowden shod behind."

Readers of Homer, and of the Chanson de Roland, must have observed the same primitive luxury of gold in these early epics.

Next as to talking-birds. These are not so common as in *Märchen*, but still are very general, and cause no surprise to their human listeners. The omniscient popinjay, who "up and spoke" in the Border minstrelsy, is of the same family of birds as those that, according to Talvj, pervade Servian song; as the τριὰ πουλακιά which introduce the story in the Romaic ballads; as the wise birds whose speech is still understood by exceptionally gifted Zulus; as the wicked dove that whispers temptation in the sweet French folk-song; as the "bird that came out of a bush, on water for to dine," in the *Water o' Wearies Well*.

In the matter of identity of plot and incident in the ballads of various lands, it is to be regretted that no such comparative tables exist as Von Hahn tried, not very exhaustively, to make of the "story-roots" of *Märchen*. A common plot is the story of the faithful leman, whose lord brings home "a braw new bride," and who recovers his affection at the eleventh hour. In Scotland this is the ballad of Lord Thomas, and Fair Annie; in Danish it is Skiaen Anna. It occurs twice in M. Fauriel's collection of Romaic songs. Again, there is the familiar ballad about a girl who pretends to be dead, that she may be borne on bier to meet her lover. This occurs not only in Scotland, but in the popular songs of Provence (collected by Damase Arbaud) and in those of Metz (Puymaigre), and in both countries an incongruous sequel tells how the lover tried to murder his bride, and how she was too cunning, and drowned him. Another familiar feature is the bush and briar, or the two rose trees, which meet and plait over the graves of unhappy lovers, so that all passers-by see them, and say in the Provençal,—

"Diou ague l'amo
Des paures amourous."

Another example of a very wide-spread theme brings us to the ideas of the state of the dead revealed in folk-songs. *The Night Journey*, in M. Fauriel's Romaic collection, tells how a dead brother, wakened from his sleep of death by the longing of love, bore his living sister on his saddle-bow, in one night, from Baghdad to Constantinople. In Scotland this is the story of Proud Lady Margaret; in Germany it is the song which Bürger converted into Lenore; in Denmark it is Aagé und Elsé; in Brittany the dead foster-brother carries his sister to the apple close of the Celtic paradise (*Barzaz Breiz*). Only in Brittany do the sad-hearted people think of the land of death as an island of Avalon, with the eternal sunset lingering behind the flowering apple trees, and gleaming on the fountain of forgetfulness. In Scotland the channering worm doth chide even the souls that come from where, "beside the gate of Paradise, the birk grows fair enough." The Romaic idea of the place of the dead, the garden of Charon, whence "neither in spring or summer, nor when grapes are gleaned in autumn, can warrior or maiden escape," is likewise pre-Christian. In Provençal, Danish, and Yorkshire folk-song, the cries of children ill-treated by a cruel step-mother awaken the departed mother,—

"'Twas cold at night and the bairnies grat,
The mother below the mouls heard that."

She reappears in her old home, and henceforth, "when dogs howl in the night, the step-mother trembles, and is kind to the children." To this identity of superstition we may add the less tangible fact of identity of tone. The ballads of Klephtic exploits in Greece match the Border songs of Dick of the Law and Kinmont Willie. The same simple delight of living animates the short Greek *Scholia* and their counterparts in France. Everywhere in these happier climes, as in Southern Italy, there are snatches of popular verse that make but one song of rose trees, and apple blossom, and the nightingale that sings for maidens loverless,—

"Il ne chante pas pour moi,
Je'n ai un, Dieu merci,"

says the gay French refrain.

It would not be difficult to multiply instances of resemblance between the different folk-songs of Europe; but enough has, perhaps, been said to support the position that they are popular and primitive in the same sense as *Märchen*. They date from times, and are composed by

peoples who find, in a natural improvisation, a natural utterance of modulated and rhythmic speech, the appropriate relief of their emotions, in moments of high-wrought feeling or on solemn occasions. "Poesie" (as Puttenham well says in his *Art of English Poesie*, 1589) "is more ancient than the artificiall of the Greeks and Latines, and used of the savage and uncivill, who were before all science and civilitie. This is proved by certificate of merchants and travellers, who by late navigations have surveyed the whole world, and discovered large countries, and wild people strange and savage, affirming that the American, the Perusine, and the very Canniball do sing and also say their highest and holiest matters in certain riming versicles." In the same way Aristotle, discoursing of the origin of poetry, says (*Poet.*, c. iv.), ἐγέννησαν τὴν ποίησιν ἐκ τῶν αὐτοσχεδιασμάτων. M. de la Villemarqué in Brittany, M. Pitré in Italy, Herr Ulrich in Greece, have described the process of improvisation, how it grows out of the custom of dancing in large bands and accompanying the figure of the dance with song. "If the people," says M. Pitré, "find out who is the composer of a *canzone*, they will not sing it." Now in those lands where a blithe peasant life still exists with its dances, like the *kolos* of Russia, we find ballads identical in many respects with those which have died out of oral tradition in these islands. It is natural to conclude that our ballads too were first improvised, and circulated in rustic dances. We learn from M. Bujeaud and M. de Puymaigre in France, that all ballads there have their air or tune, and that every dance has its own words, for if a new dance comes in, perhaps a fashionable one from Paris, words are fitted to it. Is there any trace of such an operatic, lyrical, dancing peasantry in austere Scotland? We find it in Gawin Douglas's account of—

> "Sic as we clepe wenches and damosels,
> In gersy greens, wandering by spring wells,
> Of bloomed branches, and flowers white and red,
> Plettand their lusty chaplets for their head,
> Some sang ring-sangs, dances, ledes, and rounds."

Now, ring-sangs are ballads, dancing songs; and *Young Tamlane*, for instance, was doubtless once danced to, as we know it possessed an appropriate air. Again, Fabyan, the chronicler (quoted by Ritson) says that the song of triumph over Edward II., "was after many days sung *in dances*, to the carols of the maidens and minstrels of Scotland." We might quote the *Complaynt of Scotland* to the same effect. "The shepherds, and their wyvis sang mony other melodi sangs, . . . than efter this sueit celestial harmony, tha began to dance in ane ring." It is natural to conjecture that, if we find identical ballads in Scotland, and in Greece, and Italy, and traces of identical customs,—customs crushed by the Reformation, by Puritanism, by modern so-called civilisation,—the ballads sprang out of the institution of dances, as they still do in warmer and pleasanter climates. It may be supposed that legends on which the ballads are composed, being found as they are from the White Sea to Cape Matapan, are part of the stock of primitive folk-lore. Thus we have an immemorial antiquity for the legends, and for the lyrical choruses in which their musical rendering was improvised. We are still at a loss to discover the possibly mythological germs of the legends; but, at all events, genuine ballads may be claimed as distinctly popular, and, so to speak, impersonal in matter and in origin. It would be easy to show that survivals out of this stage of inartistic lyric poetry linger in the early epic poetry of Homer and of the French *épopées*, and that the Greek drama sprang from the sacred choruses of village vintagers. In the great early epics, as in popular ballads, there is the same directness and simplicity, the same use of recurring epithets, the "green grass," the "salt sea," the "shadowy hills," the same repetition of speeches, and something of the same barbaric profusion in the use of gold and silver. But these resemblances must not lead us into the mistake of supposing Homer to be a collection of ballads, or that he can be properly translated into ballad metre. The *Iliad* and the *Odyssey* are the highest form of an artistic epic, not composed by piecing together ballads, but developed by a long series of noble ἀοιδοί, for the benefit of the great houses which entertain them, out of the method and materials of popular song. Ballads sprang from the very heart of the people, and flit from age to age, from lip to lip of shepherds, peasants, nurses, of all the class that continues nearest to the state of natural men. They make music with the plash of the fisherman's oars and the hum of the spinning-wheel, and keep time with the step of the ploughman as he drives his team. The country seems to have aided man in their making; the bird's note rings in them, the tree has lent her whispers, the stream its murmur, the village-bell its tinkling tune. The whole soul of the peasant class breathes in their burdens, as the great sea resounds in the shells cast up on the shores. Ballads are a voice from secret places, from silent peoples, and old times long dead; and as such they stir us in a strangely intimate fashion to which artistic verse can never attain.

The works of the following authors will be found useful to the student of ballads:—Talvj, *Charakteristik der Volkslieder*, dealing chiefly with the northern races of Europe, and with some African and Asiatic tribes; Kretschmar's *Volkslieder;* J. Grimm, in several treatises. For Brittany—Marquis de la Villemarqué's *Barzaz Breiz;* also M. Luzel's *Chansons Populaires.* For France—Bugeaud, *Chansons Populaires;* De Puymaigre (for the Metz district), Damase Arbaud (for Provence); Champfleury's large collection is rather miscellaneous. The quarterly journal, *Roumania*, publishes many folk-songs. For Greece—Fauriel, Passow, Le Grand. For Italy—Pitré and Nigra. For Scotland—Scott, Jamieson, Motherwell. (A. L.)

BALLANCHE, Pierre Simon, a distinguished French philosopher of the theocratic school, was born at Lyons in 1776. His health from infancy was extremely delicate, his nervous system was weak, and he was frequently subject to hallucinations and mental disorders. This weakness was much aggravated by his experience of the horrors consequent on the insurrection at Lyons and the siege of that town, during which he and his mother were compelled to take refuge in the country. His education seems never to have been very complete; but he was early imbued with ideas on the construction of society, which naturally sprang from the events of the revolutionary period. His first literary effort was an epic poem, describing the occurrences at Lyons; this he never published. In 1801 he wrote an essay *Du Sentiment considéré dans la littérature et dans les Arts*, a work which shows very well the defects as well as the merits of his style and manner of thinking. It is essentially unsystematic; and the few good ideas contained in it are expressed in language so figurative that it costs an effort to discover what is really being said. Ballanche, indeed, was essentially unsystematic and unscientific, and seems to have had no conception of what is truly required in a philosophy. His style is not external to the thinking, but is undissolubly connected with it; strange thoughts and *bizarre* expressions arise together.

His next great work, the *Antigone*, a prose poem, published in 1814, was the fruit of long and quiet meditation, and was received with great favour by the brilliant literary society surrounding Chateaubriand and Mme. Récamier, into which Ballanche had been introduced. From this year, 1814, dates his serious effort towards a speculative reconstruction of society, an exposition of the *palingenesis* of social order. He transferred his residence to Paris, where he continued to live in communication with the few thinkers who had like philosophical tendencies with himself. In 1817 appeared his *Essai sur les Institutions*

Sociales dans leur rapport avec les Idées nouvelles, which was intended to serve as a prelude to his great tripartite social epic. The work is more intelligible than any other of Ballanche's; it advocates a moderate constitutional government, and was, on this account, misjudged by many, who fancied it recommended Bourbonism. A philosophical dialogue, *Le Vieillard et le Jeune Homme*, and a novel, *L'Homme sans Nom*, were written in 1819 and 1820. He then devoted himself to his great work, the *Palingénésie Sociale*. This, which was to be a *Theodicæa*, an exposition of the workings of God in history, was divided into three parts: the first reconstructed that period of the world which was before the rise of religion, which is prehistoric, or mythical; the second endeavoured, from a study of known history, to deduce a universal law or rule; the third sketched that state of things through and in which humanity at last attains its final end and crowning glory. The works representing these three parts were called *L'Orphée*, *La Formule*, and *La Ville des Expiations;* only the first was completed, but some fragments of the others are in existence. To the whole a general introduction was prefixed, which is the most valuable of all Ballanche's works. His latest writing, *Vision d'Hébal* (Hebal being the chief of a Scottish clan, and gifted with second sight), was evidently intended to form portion of the third part of the *Palingénésie*. In mystical language it gives vague and semi-prophetic utterances on the future course of world-history. It is by some considered his greatest production. Ballanche, who in 1841 had received the distinguished honour of a seat in the French Academy, died in 1847. He was much beloved by his friends, and seems to have been a most amiable, warm-hearted man, enthusiastic and poetical in temperament, whose intellect, however, was overshadowed by his imagination. A collected edition of his works was set on foot in 1830, and was intended to occupy nine vols. Only four appeared, and were republished in a smaller form in 1833.

It is almost impossible to give a connected view of Ballanche's fundamental ideas. As has been said, he belonged to the theocratic school, who, in opposition to the rationalism of the preceding age, emphasised the principle of authority, placing revelation above individual reason, order above freedom and progress. But Ballanche made a sincere endeavour to unite in one system what was valuable in the opposed modes of thinking. He held with the theocratists that individualism was an impracticable view; man, according to him, exists only in and through society. He agreed further with them that the origin of society was to be explained, not by human desire and efforts, but by a direct revelation from God. Lastly, with De Bonald, he reduced the problem of the origin of society to that of the origin of language, and held that language was a divine gift. But at this point he parts company with the theocratists, and in this very revelation of language finds a germ of progress. Originally, in the primitive state of man, speech and thought are identical; but gradually the two separate; language is no longer only spoken, it is also written, and finally is printed. Thus the primitive unity is broken up; the original social order which co-existed with, and was dependent on it, breaks up also. New institutions spring up, upon which thought acts, and in and through which it even draws nearer to a final unity, a rehabilitation, a *palingenesis*. The volition of primitive man was one with that of God, but it becomes broken up into separate volitions which oppose themselves to the divine will, and through the oppositions and trials of this world work onwards to a second and completer harmony. The history of humanity is therefore comprised in the fall from the perfect state, and in the return, after repeated trials, to a similar condition. In the dim, shadowy records of mythical times may be traced the obscure outlines of primitive society and of its fall; and this is attempted in the *Orphée*. Actual history exhibits the conflict of two great principles, which may be said to be realised in the patricians and plebeians of Rome. Such a distinction of caste is regarded by Ballanche as the original state of historical society; and history, as a whole, he considers to have followed the same course as that taken by the Roman plebs in its gradual and successful attempts to attain equality with the patriciate. On the future events through which the human race shall achieve its destiny Ballanche gives few intelligible hints. The sudden flash which disclosed to the eyes of Hebal the whole epic of humanity cannot be reproduced in language trammelled by time and space. Scattered throughout the works of Ballanche are many valuable ideas on the connection of events which makes possible a philosophy of history; but his own theory, so far as it can be understood and judged, does not seem likely to find more favour than it has already met with.

See Ampère, *Ballanche*, Paris, 1848; Ste. Beuve, *Portraits Contemporaines*, vol. ii.; Damiron, *Philosophie de* XIX^me *Siècle*. An admirable analysis of the works composing the *Palingénésie* is given by Barchou, *Revue de deux Mondes*, 1831, t. 2. pp. 410–456.

BALLARAT, or BALLAARAT, a large and flourishing city of Australia, in the province of Victoria. It is situated about 58 miles N.W. of Geelong, with which it is connected by railway, and about 66 miles W.N.W. of Melbourne, at an elevation of 1437 feet above the level of the sea, on a small river known as the Yarowee Creek. It consists of three portions,—Ballarat West, Ballarat East, and Sebastopol,—each of which has its own municipality and town-hall. Its existence and prosperity are solely due to the gold-fields which were discovered here in 1851. In 1855 it was proclaimed a municipality, and in 1870 Ballarat West was raised to the rank of a city. In 1871 it contained 56 churches, 477 hotels, 10,000 dwellings, 11 banks, 8 iron-foundries, 13 breweries and distilleries, 3 flour-mills, a free public library, a mechanics' institute, a hospital, a "benevolent institution," a theatre, and a public garden; while about sixty miles of water-mains and fifty of gas-mains had been laid down. Its population—of very various origin, and including a large number of very degraded Chinese, who are huddled together in a separate quarter—then amounted to 48,156.

BALLÁRÍ [BELLARY], a district in the Madras Presidency, lies between 13° 40′ and 15° 58′ N. lat., 75° 44′ and 78° 19′ E. long. It is bounded on the N. by the Nizám's territory, from which it is separated by the Tungbhadrá river; on the E. by the districts of Kadapa and Karnúl; on the S. by the Mysore country; and on the W. by Mysore, and the Bombay district of Dharwar. Its extreme length from north to south is 170 miles, and its breadth from east to west about 120 miles. The area of the district, including 145 square miles of the Sandúr State, is estimated at about 11,496 square miles; according to other returns, the area is 10,857 square miles (excluding Sandúr), of which 1004 consists of barren soil, sites of villages, beds of water-courses, &c., and 9852 of lands either actually cultivated or capable of cultivation. The census of 1871 returned the population at 1,652,044, of whom 94 per cent. were Hindus. It is estimated that 941,712, or 71·8 per cent. of the population, live by agriculture. The general aspect of the district is that of an extensive plateau between the Eastern and Western Gháts, of an average height of from 800 to 1000 feet above sea-level. The most elevated tracts are on the W., where the surface rises towards the culminating range of hills, and on the S., where it rises to the elevated table-land of Mysore. Towards the centre the surface of the plain presents a monotonous aspect, being almost treeless, and unbroken

save by a few rocky elevations that stand forth abruptly from the sheet of black soil below. The hill ranges in Ballárí are those of Sandúr and Kampli to the W., the Lanká Malla to the E., and the Copper mountain to the S.W. The last has an elevation of 3148 feet. The district is watered by five hill streams, viz., the Tungbhadrá, formed by the junction of two small rivers, Tung and Bhadrá, the Haggarí, Hindrí, Ponnár, and Chitravatí. The Ponnár is considered a sacred river by the natives. None of the rivers are navigable, and all are fordable during the dry season.

The agricultural products of the district are cotton, indigo, wheat, rice, sugar-cane, flax, betel, plantain, turmeric, chillies, onions, hemp, coriander, tobacco, areca-nut, cocoa-nut, oil-seeds, &c. The following is a rough estimate of acreage under different crops:—Food grains, 2,687,000 acres; oil-seeds, 103,000 acres; green and garden crops, 36,000 acres; orchards, 18,000 acres; cotton, indigo, and sugar-cane, 37,000 acres; fallow, 541,000 acres; total, 3,922,000 acres. The manufactures of the district consist of cotton goods, tape, carpets, rope, blankets, felts, dyes, oil, sugar and molasses, paper, leather, glass bangles or bracelets, and iron and earthen pots. Cotton, blankets, raw hides, iron, &c., form the articles of export. The chief mineral products are iron, copper, lead, antimony, manganese, alum, and gun-flints. Among precious stones diamonds are found, the chief diamond mines being at Munimadagu and Wajrákarúr. The diamonds are collected in the sandstone breccia and conglomerate. The mines no longer yield sufficient profit to be regularly worked, though every now and then diamonds of small value are met with. The revenue of the Ballarí district from all sources amounted in 1845 to £257,199; in 1855 to £248,284; and in 1868 to £322,548. The land tax forms the principal source of revenue. In 1868 it yielded £242,684. More than one-fourth of the lands are held as *Inám, i.e.*, under grants formerly made for services or for religious purposes. These were very lightly taxed by the native Governments, but the present state of their assessment is not less than that of ordinary lands. The police force numbered 1122 in 1871, maintained at a cost of £16,012. In 1870–71 the district contained 153 schools, attended by 4274 pupils. It has only seven towns with a population of more than 7000 souls—(1), Ballárí, population, including troops in the cantonment, 51,145; (2), Hospettá, 9845; (3), Tádipatri, 8182; (4), Harpanhallí, 7895; (5), Ráidrug, 7734; (6), Emmiganur, 7326; and (7), Yadikí, 7202. Only four municipal towns exist in the district:—1. Ballárí—population, 51,145; municipal income in 1871, £7651; expenditure, £7495; rate of taxation, 2s. 3⅝d. per head. 2. Gutti—population, 6033; municipal income £992; expenditure, £930; rate of taxation, 3s. 3½d. per head. 3. Anantpur—population, 4971; municipal income, £794; expenditure, £784; rate of taxation, 3s. 2½d. per head. 4. Adoni—municipal income, £2147; expenditure, £1905. Fifty-nine roads, of a total length of 1465 miles, connect the different towns and villages in the Ballárí district; and the Madras Railway, with a branch to Ballárí, passes through it. The climate of Ballarí is characterised by extreme dryness, in consequence of the air passing over a great extent of heated plains, and it has a smaller rain-fall than any other district in South India. The average daily range of the thermometer is from 67° to 83°; average rain-fall for the five years ending 1869, 17 inches. The prevailing diseases are cholera, fever, small-pox, ophthalmia, dysentery, and skin diseases among the lower classes. Ballárí is subject to disastrous storms and hurricanes, and to famines arising from a series of bad seasons. The storms of 1804 and 1851, and the famines of 1751, 1792, 1793, 1803, 1833, 1854, and 1866 still live in the popular memory.

Little is known of the early history of the district. It appears to have been a portion of the ancient kingdom of Vijayanagaram, and on the overthrow of that state in 1564 A.D. by the Mahometans, the tract now forming the district of Ballárí was split up into a number of military holdings, held by chiefs called Poligárs. In 1635 the Carnatic was annexed to the Bijápur dominions, from which again it was wrested in 1680 by Sivají, the founder of the Marhattá power. It was then included in the dominions of Nizám-ul-mulk, the nominal viceroy of the Great Mughul in the Dakhín, from whom again it was subsequently conquered by Haidar Alí of Mysore. At the close of the war with Tipú Sultán in 1792, the territories which now form the Ballárí district fell to the share of the Nizám of Haidarábád, by whom it was ceded to the British in 1800, in return for a force of English troops to be stationed at his capital. In 1818 the district of Ballárí was constituted as it at present remains. Amidst all these political convulsions the little state of Sandúr, occupying a central position in the Ballárí district, and surrounded by a cordon of hills, preserved its integrity. Sandúr can only be entered by one of three principal natural passes, viz., the Bhimagundí pass on the N.E., the Rámanagungí pass on the N., and the Oblagundí pass on the W. Its chief is the representative of one of the most ancient Marhattá families, and derives a revenue of £4500 from his state. He now holds Sandúr as a *Jágír* or a military tenure from our Government, but pays no tribute.

BALLÁRÍ, the principal town of the above district, is the chief seat of the judicial and revenue establishments, and the headquarters of the military force in the ceded districts consisting of Ballárí and Kadapa. The fort rises from a huge mass of granitic rocks, which jut up abruptly to a height of 450 feet above the plain, with a circumference of nearly 2 miles. Its length from north-east to south-west is about 1150 feet. To the E. and S. of the Ballárí rock lies a heap of boulders irregularly piled one on the other, but to the W. is an unbroken surface of sheet-rock, while the N. is walled by bare rugged ridges. Ballárí rock is defended by two distinct lines of works, the upper and the lower fort. The upper fort is a quadrangular building on the summit of the rock, with only one way up to it, and deemed impregnable by the Mysore princes. But as it has no accommodation for a garrison, it is now unoccupied by our troops, with the exception of a small guard in charge of prisoners. The ex-Nawáb of Karnúl was confined in it for forty years for the murder of his wife. It contains several tanks or cisterns excavated in the rock. Outside the turreted rampart are a ditch and covered way. The lower fort lies at the eastern base of the rock, and measures about half a mile in diameter. It contains the barracks for our troops, the arsenal and commissariat stores, the Protestant church, orphanage, Masonic lodge, post-office, and numerous private dwellings. The fort of Ballárí was originally built by one Timmapa, in the 16th century. It was first dependent on the kingdom of Vijayanagaram, afterwards on Bijápur, and subsequently subject to the Nizám and Haidar Alí. The latter improved the fortifications with the assistance of French artisans, whom he afterwards hanged for not building the fort on a higher rock adjacent to it. The cantonment bázár of Ballárí enjoys the reputation of being the best military bázár in Southern India. To the W. of the rock are the regimental lines for two Native infantry regiments, one European regiment, and one regiment of cavalry. On the E. are the jail, the public courts, and the terminus of the branch line of the Madras Railway. Ballárí town, including the cantonment, contained in 1866 a population of 37,015 souls, of which 13,341 were Hindus, 4178 Mahometans, and 1042 Christians. Population ascertained by the census of 1871, 51,145. Elevation above the sea, 1600 feet. Distance from Bombay, S.E., 380 miles; from Madras, N.W., 270 miles. Lat. 15° 18′ N.; long. 76° 59′ E.

BALLATER, a village of Aberdeenshire, Scotland, on the River Dee, 42 miles W. from Aberdeen. In its vicinity are the medicinal wells of Pannanich, Balmoral Castle (a summer residence of Queen Victoria), and Ballatrich Farm where Byron spent part of his boyhood. Ballatrich is a short distance from "Lachin-y-Gair" (Lochnagar), one of the loftiest of the Grampian range, and the subject of one of Byron's most beautiful poems.

BALLENSTEDT, a city in the duchy of Anhalt-Bernburg. It is situated on the Getel in the Harz Forest, in a most picturesque district, and consists of an old and a new town. A fine road, bordered with trees, leads to the castle of the dukes of Anhalt-Bernburg. The city contains about 4395 inhabitants, who are mostly engaged in linen manufactures, gardening, &c. Ballenstedt is the birthplace of Joh. Arndt.

BALLET is a word, the signification of which depends upon the century in which we find it employed. Originally derived from the Greek βαλλίζειν, to dance, it has passed through the mediæval Latin *ballare* (with *ballator* as synonymous with *saltator*) to the Italian *ballare* and *ballata*, to the French *ballet*, to the old English word *ballette*, and to *ballad*. In old French, according to Rousseau, *ballet* signifies "to dance, to sing, to rejoice;" and thus it incorporates three distinct modern words, "ballet, ball, and ballad." Through the gradual changes in the amusements of different ages, the meaning of the first two words has at length become limited to dancing, and the third is now confined to singing. But, although ballads are no longer the vocal accompaniments to dances round the maypole, our old ballads are still sung to dance tunes. The present acceptation of the word *ballet* is—a theatrical representation in which a story is told only by gesture, accompanied by music which should be characterised by stronger emphasis than would be employed with the voice. The dancing should be connected with the story, but is more commonly incidental. The French word was found to be so comprehensive as to require further definition, and thus the above-described would be distinguished as the *ballet d'action* or pantomime ballet, while a single scene, such as that of a village festival with its dances, would now be termed a *divertissement*.

The *ballet d'action*, to which the changed meaning of the word is to be ascribed, and therewith the introduction of modern ballet, has been generally attributed to the 16th century. Novelty of entertainment was then sought for in the splendid courts of Italy, in order to celebrate events which were thought great in their time, such as the marriages of princes, or the triumphs of their arms. Invention was on the rack for novelty, and the skill of the machinist was taxed to the utmost. It has been supposed that the art of the old Roman *pantomimi* was then revived, to add to the attractions of court-dances. Under the Roman empire the *pantomimi* had represented either a mythological story, or perhaps a scene from a Greek tragedy, by mute gestures, while a chorus, placed in the background, sang *cantica* to narrate the fable, or to describe the action of the scene. The question is whether mute pantomimic action, which is the essence of modern ballet, was carried through those court entertainments, in which kings, queens, princes, and princesses took parts with the courtiers; or whether it is of later growth, and derived from professional dancers upon the stage. The former is the general opinion, but an analysis of the only ballet which is known to have been printed in a complete form during the 16th century, would lead to the inference that the court entertainments of Italy and France were masques, or masks, which included declamation and song, like those of Ben Jonson with Inigo Jones for the court of James I.

The introduction of the Italian style of ballet into France was on the occasion of the marriage of the Duc de Joyeuse with Mdlle. de Vaudemont, sister to the queen. This was in 1581; and the ballet was printed in 1582, in a small folio of eighty-two leaves, with music, dialogue, engravings of the scene and of the fancy dresses, and full details of the plot. It is entitled *Balet Comique de la Royne*, because the queen took a part in it, as one of the naiades, with her ladies; but they were only posed upon machinery to be looked at, and neither spoke nor sang. One lady of the court sang a song, two others a duet, and, again, others a chorus. Jupiter and Mercury each sang a song, but Circe and the rest spoke poetry. The king's musicians, as tritons, were the mainstays of the music; the ladies and gentlemen of the court appeared in splendid fancy dresses, and danced the entrées. The inventor of the ballet was Baltazarini Belgioioso, who had assumed the name of Baltasar de Beaujoyeux upon his appointment as first musician to Catherine de Medicis, queen dowager of France. The disuse of dialogue and of vocal music in ballet seems to have been arrived at only by degrees. One of the most complete books upon the subject is by the Jesuit Le Père Menestrier (Claude 'François) *Des Ballets Anciens et Modernes*, 12mo, 1681. He was the inventor of a ballet for Louis XIV. in 1658; and in his book he analyses about fifty of the early Italian and French ballets. His definition is as follows:—"Ballets are dumb comedies, which should be divided into acts and scenes, like other theatrical pieces. Recitations divide them into acts, and the entrées of dancers are equal in number to the scenes." So recitation had not then been dispensed with. At length the opinion gained ground that, in stage representations, the actions, feelings, and passions could be more faithfully, gracefully, and intelligibly expressed to the eye by pantomimic action, than it would be possible to do to the ear. The art of dramatic expression then became a greater object of study; and, perhaps, from about the middle of the last century, or in the time of Noverre, the spectators have been prepared only by a short printed summary of the story which was to be represented. (W. CH.)

BALLINA, a seaport and market-town of Ireland, county of Mayo, 18 miles N.N.E. of Castlebar, situated on the River Moy, which is here crossed by two bridges. It has a parish and a Roman Catholic Church (the latter being in the suburb of Ardnaree on the opposite side of the river), Baptist and Methodist chapels, a court-house, three branch banks, a workhouse, hospital, dispensary, barracks, and several schools. A convent was erected in 1867. The salmon fishery and fish-curing are important branches of its trade; and it has also breweries and flour-mills, and manufactures snuff and coarse linen. The amount of harbour receipts in 1873 was £1266. In 1798 Ballina was for a short time in the possession of the French, under General Humbert. In the neighbourhood there is an interesting dolmen, proved by the early annals of Ireland to belong to the 5th century A.D. (*vide* Fergusson's *Rude Stone Monuments*). To the east of the village are the remains of an abbey, with a Gothic door-case in fine preservation (Archdall). Population in 1871, 5551.

BALLINASLOE, a town of Ireland, province of Connaught, 91 miles W.S.W. of Dublin. The River Suck, an affluent of the Shannon, divides it into two parts; the western being in the county of Galway, the eastern in the county of Roscommon. They are connected by two bridges and a causeway across an island. The town is clean and well built, and contains a handsome church, with a singular octagonal spire springing from scrolls. There are Roman Catholic and Methodist chapels, several public schools, a district lunatic asylum, union workhouse, market-house, a savings bank (established in 1822), several flour-mills, and breweries. In the neighbourhood is Garbally Castle, the seat of the earl of Clancarty. A great annual cattle fair is held here from the 5th to the 9th of October. Its importance may be judged from the fact, that in 1874 there were exposed for sale 18,018 horned cattle and 65,130 sheep. The *Western Star* is published in the town. Population in 1871, 4619.

BALLOON. See AERONAUTICS, vol. i. pp. 187–207.

BALLOT, or secret voting, has been employed in political, legislative, and judicial assemblies, and also in the proceedings of private clubs and corporations. At Athens, the dicasts, in giving their verdict, generally used balls of stone (*psephi*) or of metal (*sponduli*). Those pierced in the centre, or black in colour, signified condemnation; those unpierced, or white, signified acquittal. The boxes were variously arranged; but generally a brass box received both classes of votes, and a wooden box received the unused balls. In the assembly, cases of *privilegia*, such as ostracism,

the naturalisation of foreigners, or the release of state-debtors, were decided by secret voting. The petalism, or voting by words on olive-leaves, practised at Syracuse, may also be mentioned. At Rome the ballot was introduced to the comitia by the *Leges Tabellariae*, of which the *Lex Gabiana* (139 B.C.) relates to the election of magistrates, the *Lex Cassia* (137 B.C.) to *judicia populi*, and the *Lex Papiria* (131 B.C.) to the enactment and repeal of laws. The wooden *tabellae*, placed in the *cista*, or wicker box, were marked U. R. (*uti rogas*) and A. (*antiquo*) in the case of a proposed law; L. (*libero*) and D. (*damno*) in the case of a public trial; in the case of an election, *puncta* were made opposite the names or initials of the candidates. *Tabellae* were also used by the Roman judices, who expressed their verdict or judgment by the letters A. (*absolvo*), C. (*condemno*), and N. L. (*non liquet*).[1]

cat itain.

In Great Britain the ballot was suggested for use in Parliament by a political tract of the time of Charles II. It was actually used by the Scots Parliament of 1662 in proceeding on the "Billeting Act," a measure proposed by Middleton to secure the ostracism of Lauderdale and other political opponents who were by secret vote declared incapable of public office. The plan followed was this: each member of Parliament wrote, in a disguised hand, on a piece of paper, the names of twelve suspected persons; the billets were put in a bag held by the registrar; the bag was then sealed, and was afterwards opened and its contents ascertained in the Exchequer Chamber, where the billets were immediately burned, and the names of the ostracised concealed on oath. The Billeting Act was repudiated by the king, and the ballot was not again heard of till 1705, when Fletcher of Saltoun, in his measure for a provisional government of Scotland by annual Parliaments in the event of Queen Anne's death, proposed secret voting to protect members from court influence. The gradual emancipation of the British Parliament from the power of the Crown, and the adoption of a strictly representative system of election, have not only destroyed whatever reason may once have existed for the ballot in deliberative voting, but have rendered it essential that such voting should be open. It was in the agitations for parliamentary reform at the beginning of the 19th century that the demand for the ballot in parliamentary elections was first seriously made. The Benthamites advocated the system in 1817.[2] At the Peterloo Massacre (1819) several banners were inscribed with the ballot. O'Connell introduced a bill on the subject in 1830; and the original draft of Lord John Russell's Reform Bill, probably on the suggestion of Lords Durham and Duncannon, provided for its introduction. Later on Mr Grote became its chief supporter in the House of Commons; and from 1833 to 1839, in spite of the ridicule cast by Sydney Smith on the "mouse-trap," and on Mr Grote's "dagger-box, in which you stab the card of your favourite candidate with a dagger,"[3] the minority for the ballot increased from 106 to 217. In 1838 the ballot was the fourth point of the People's Charter. In the same year the abolition of the land qualification introduced rich commercial candidates to the constituencies. Lord Melbourne's cabinet declared the question open. The cause, upheld by Macaulay, Ward, Hume (in his resolutions, 1848), and Berkeley, was strengthened by the Report of Lord Hartington's Select Committee (15th March 1870),[4] to the effect that corruption, treating, and intimidation by priests and landlords took place to a large extent at both parliamentary and municipal elections in England and Ireland; and that the ballot, if adopted, would probably not only promote tranquillity at elections, but protect voters from undue influence, and introduce greater freedom and purity in voting, provided secrecy was made inviolable except in cases where a voter was found guilty of bribery, or where an invalid vote had been given. At Manchester and Stafford in 1869, test ballots had taken place on the Australian principle as practised in Victoria,—the voting card containing the names of all the candidates, printed in different colours (for the benefit of illiterate voters), and the voter being directed to score out the names of those he did not support, and then to place the card (covered by an official envelope) in the box. It was found at Manchester that the voting was considerably more rapid, and therefore less expensive, than under the old system; that only 80 cards out of 11,475 were rejected as informal; and that, the representatives of candidates being present to check false statements of identity, and the public outside being debarred from receiving information what voters had voted, the ballot rather decreased the risk of personation. At Manchester the cards were not numbered consecutively, as is done in Victoria, so that (assuming the officials to be free from corruption) no scrutiny could have detected by whom particular votes were given. At Stafford the returning officer stamped each card before giving it to the voter, the die of the stamp having been finished only on the morning of the election. By this means the possibility was excluded of what was known in the colonies as "the Tasmanian Dodge," by which a corrupt voter gave to the returning officer, or placed in the box, a blank non-official ticket, and carried out from the booth his official card, which a corrupt agent then marked for his candidate and gave, so marked, to corrupt voter No. 2 (before he entered the booth), on condition that he also would bring out his official card, and so on *ad libitum*; the agent thus obtaining a security for his bribe, unless the corrupt voter chose to disfranchise himself by making further marks on the card.

At the close of 1870 the ballot was employed in the election of members for the London School Board, under the Education Act of that year.

In 1872 Mr Forster's Ballot Act (35 and 36 Vict. c. 33) introduced the ballot in all parliamentary and municipal elections, except parliamentary elections for universities; and the code of procedure prescribed by the Act was adopted by the Scotch Education Board in the first School Board election (1873), under "The Education (Scotland) Act, 1872." It is impossible here to analyse the Ballot Act, which not only abolishes public nominations of candidates, but deals with the offence of personation and the expenses of elections. As regards the ballot, a white paper is used on which the names of the candidates are printed in alphabetical order, the voter filling up with a X the blank on the right hand opposite the name he votes for. The paper, before being given out, is marked by the presiding officer on both sides with an official stamp, which is kept secret, and cannot be used for a second election within seven years. The paper is marked on the back with the same number as the counterfoil of the paper which remains with the officer. This counterfoil is also marked with the voter's number on the register, so that the vote may be identified on a scrutiny; and a mark on the register shows that the voter has received a ballot paper. The voter folds up the paper so as to conceal his mark, but to show the stamp to the officer, and deposits it in the box, which is locked and sealed, and so constructed that papers cannot be withdrawn without unlocking it. Papers inadvertently spoiled by the voters may be exchanged, the officer preserving separately the spoiled papers. If a voter is incapacitated from blindness, or other physical cause, or

[1] In Saxony juries still vote by ballot.

[2] See the powerful article by James Mill, *Westminster Rev.*, vol. xiii.

[3] For a description of Mr Grote's card-frame, in which the card was punctured through a hole, and was thus never in the voter's hands, see *Spectator*, 25th February 1837.

[4] Parliamentary Papers, 1868-9, R. 352, 352-I.; and 1870, R. 115.

makes before the officer a declaration of inability to read, or when the poll is on a Saturday declares himself a Jew, the officer causes the paper to be marked as the voter directs, and keeps a record of the transaction. A voter who claims to vote after another has voted in respect of the same qualification, obtains a (green) paper which is not placed in the box, but preserved apart as a "tendered" paper. He must, however, declare his identity, and that he has not already voted. The presiding officer, at the close of the poll, has to account to the returning officer for the papers entrusted to him, the number being made up by—(1) papers in the box, (2) spoiled papers, (3) unused papers, and (4) tendered papers. During the voting (for which schoolrooms and other public rooms are available, and for which a separate compartment must be provided for every 150 electors entitled to vote at a station) agents of candidates are allowed to be present in the polling-station, but they, as well as the officials, are sworn to secrecy as regards who have voted, and for whom; and they are prohibited from interfering with the voter, inducing him to show his vote, or attempting to ascertain the number on the back of the paper. These agents are also present with the returning officer when he counts the papers and the votes, rejecting those papers (1), which want the official mark *on the back*; (2), on which votes are given for more candidates than the voter is entitled to vote for; (3), on which anything except the number on the back is marked or written by which the voter can be identified; (4) which are unmarked, or so marked that it is uncertain for whom the vote is given. The counted and rejected papers, and also the "tendered" papers, counterfoils, and marked register (which have not been opened), are, in parliamentary elections, transmitted by the returning officer to the clerk of the Crown in Chancery in England, or the sheriff-clerk in Scotland, who destroys them at the end of one year, unless otherwise directed by an order of the House of Commons, or of some court having jurisdiction in election petitions. Such petitions either simply dispute the accuracy of the return on the ground of miscounting, or wrongous rejection or wrongous admission of papers, in which case the court examines the counted and rejected papers; or make allegations of corruption, &c., on which it may be necessary to refer to the marked counterfoils and ascertain how bribed voters have voted. Since the elections of 1874 much discontent has been expressed, because judges have rejected papers with trifling (perhaps accidental) marks other than the X upon them, and because elections have been lost through the failure of the officer to stamp the papers. For this purpose the use has been suggested of a perforating instead of an embossing stamp, while a dark ground paper with white voting spaces would make *misplaced* votes impossible. The Ballot Act has introduced several new offences, such as forging or fraudulently defacing or destroying a paper or the official mark; supplying a paper without due authority; fraudulently putting into the box a non-official paper; fraudulently taking a paper out of the station without due authority; destroying, taking, opening, or otherwise interfering with a box or packet of papers then in use for election purposes. These offences and attempts to commit them, are punishable in the case of officers and clerks with imprisonment for two years, with or without hard labour. In other cases the term of imprisonment is six months.

The ballot being thus *un fait accompli* in the United Kingdom, it is now scarcely necessary to indicate the arguments by which it was supported and opposed. It has been found possible to render voting perfectly secret and to provide for a scrutiny. It would be foolish to expect that secret voting will be a perfect security for independent voting. Bribery, treating, and intimidation continue to be practised, but with diminished effect. Bribery may still be made conditional on the briber's success, but the Act is felt to be an expression of national opinion against all interference with individual judgment. The argument that the franchise is a public trust, to the exercise of which a public responsibility should attach, would be conclusive if the "selfish partialities" of the voter were the chief evil. The ballot was declared to lead to universal hypocrisy and deception; and Sydney Smith spoke of "voters, in dominos, going to the poll in sedan-chairs with closely-drawn curtains." The observed effect of a secret ballot is, however, gradually to exterminate undue influence and canvassing; and when the necessity for secrecy is removed, votes are not kept secret. The alarm of "the Confessional" seems to be unfounded, as a Catholic penitent is not bound to confess his vote, and if he did so, it would be a crime in the confessor to divulge it.

The ballot is used very largely in the British Colonies, and on the Continent. In South Australia, under the Constitution Act of 1856 and the Electoral Act of 1858, both the Legislative Council and the House of Assembly are elected by manhood suffrage under the ballot, the returning officer *putting his initials* on the voting card, which the voter is directed, under pain of nullity, to fold so that the officer may not see the vote which is indicated by a cross. The cards are destroyed when the poll is announced; and thus personation, though proved against certain voters for the purpose of punishing them, would not void an election, for there can be no scrutiny before the Court of Disputed Returns. Canvassing has almost disappeared. In Victoria, under the Electoral Act of 1865 (29 Vict. c. 279), both the Legislative Council and the Legislative Assembly are elected practically by manhood suffrage under the ballot, which was introduced in 1856. The officer adds to his initials a number corresponding to the voter's number on the register, and the cards are preserved till after the time for petitioning the Committee of Elections and Qualifications has expired, so that a scrutiny may take place of challenged votes. The important Road Boards under the Local Government Consolidation Act of 1869 are also elected by ballot. In Tasmania the chief peculiarity is that (as in South Australia) the card is not put directly by the voter into the box, but handed to the officer who puts it there (this being thought a security against double voting or voting with a non-official card, and also against the voter carrying away his card); here also the cards are destroyed immediately, while in New South Wales, where, as in Victoria, the voting is by scoring out and not by a cross, the cards are kept for five years. The vigorous municipal boards of these colonies are also elected by ballot, which has diminished expense and undue influence very greatly, but has not produced complete secrecy of voting.

Aust

In France, where from 1840 to 1845 the ballot, or *scrutin*, had been used for deliberative voting in the Chamber of Deputies, its use in elections to the Corps Législatif was carefully regulated at the beginning of the Second Empire by the Organic Decree of 2d February 1852. Under this law the voting was superintended by a bureau consisting of the deputy returning officer (called president of the section), four unpaid assessors selected from the constituency, and a secretary. Each voter presents a polling card, with his designation, date of birth, and *signature* (to secure identity), which he has previously got at the *Mairie*. This the president mutilates, and the vote is then recorded by a "bulletin," which is not official, but is generally printed with a candidate's name, and given to the voter by an agent outside, the only conditions being that the bulletin shall be "sur papier blanc, sans signes extérieurs, et préparé en dehors de l'assemblée." The

Fran

total number of votes given (there being only one member in each electoral district) is checked by reference to "la feuille *d'appel* et inscription des votants," the law still supposing that each voter is publicly called on to vote. If the voter, when challenged, cannot sign his polling card, he may call a witness to sign for him. The following classes of bulletins are rejected :—"illisibles, blancs, ne contenant pas une designation suffisante ; sur lesquels les votants se sont fait connaître; contenant le nom d'une personne n'ayant pas prêté le serment prescrit" (*i.e.*, of a person not nominated). Only the votes pronounced bad by the bureau in presence of representative scrutineers are preserved, in case these should be called for during the "Session pour vérification des Pouvoirs." Practically the French ballot did not afford secrecy, for you might observe what bulletin the voter took from the agent, and follow him up the *queue* into the polling-place; but the determined voter might conceal his vote even from the undue influence of Government by scratching out the printed matter and writing his vote. This was always a good vote, and scrutiny of good votes was impossible. The ballot is still used in the elections to the National Assembly, but in the Assembly itself only in special cases, as, *e.g.*, in the election of a "rapporteur." Under the law of 10th August 1871, the conseils généraux (departmental councils) are elected by ballot. In Piedmont the ballot formed part of the free constitutional government introduced by Charles Albert in March 1848; it was extended to Italy in 1861. Voting for the Italian Chamber of Deputies takes place under the law of 20th November 1859, and in public halls (not booths), to which admission is gained by showing a certificate of inscription, issued by the mayor to each qualified voter. A stamped blue official paper, with a memorandum of the law printed on the back (*bolletino spiegato*), is then issued to the elector; on this he writes the name of a candidate (there being equal electoral colleges), or, in certain exceptional cases, gets a confidential friend to do so, and hands the paper folded up to the president of the bureau, who puts it in the box (*urna*), and who afterwards presides at the public "squittinio dei suffragi." No scrutiny is possible; canvassing and bribery are rare; and Cavour thought the ballot had quite nullified the clerical power, at least in Piedmont. Greece is the only European country in which the ball ballot is used. The voting takes place in the churches, each candidate has a box, on which his name is inscribed, one half (white) being also marked "Yes," the other half (black) "No." The voter, his citizenship or right to vote in the eparchy being verified, receives one ball or leaden bullet for each candidate from a wooden bowl, which a clerk carries from box to box. The voter stretches his arm down a funnel, and drops the ball into the "Yes" or "No" division. The vote is secret, but there is apparently no check on "Yes" votes being given for *all the candidates*, and the ball or bullet is imitable. In the United States a most imperfect ballot system prevails. In many states there is no register, and therefore personation and double voting are practised. Again, there is no official card, but, as in the Shanty system of New York, candidates' touts give out printed and designed cards, which sometimes fraudulently imitate one another in design, so that ignorant voters are misled. Again, the ballot is generally taken in an engine-house, or shed open to the street, so that mob-intimidation may be used, and votes, as in France, are not practically secret. In Massachusetts, in 1851–2, the Know-nothing or Anti-Irish party, anxious to prevent personation, introduced a secret ballot for state elections, using the Manchester envelope and an official card, with the names of the candidates printed. This led to fraud and was abandoned, a return being made to the French system.

nited ates.

Hungary. The history of the ballot in Hungary is remarkable. Before 1848 secret voting was unknown there. The electoral law of that year left the regulation of parliamentary elections to the county and town councils, very few of which adopted the ballot. The mode of voting was perhaps the most primitive on record. Each candidate had a large box with his name superscribed, and painted in a distinguishing colour. On entering the room alone the voter received a rod from 4 *to* 6 *feet in length* (to prevent concealment of non-official rods on the voter's person), which he placed in the box through a slit in the lid. By the electoral law of 1874,[1] the ballot in parliamentary elections in Hungary is abolished, but is made obligatory in the elections of town and county councils, where votes are given *for several persons at once.*[2] This voting, however, carried on by party-lists on differently coloured cards is practically open. There is a strong feeling in Hungary that the ballot would be worked by the Catholic clergy through the Confessional. As most of the electors are freeholders, there is little intimidation. **Germany.** In Prussia, Stein, by his Stadteordnung, or Municipal Corporation Act of 1808, introduced the ballot in the election of the Municipal Assembly (*Stadt verordneten Versammlung*). Under the German Constitution of 1867, and the New Constitution of 1st January 1871, the elections for the Reichstag are conducted by universal suffrage under the ballot in conformity with the Electoral Law of 31st May 1869, which also divided Germany into equal electoral districts.

Ballot machines. To secure complete secrecy, and to avoid the possibility of fraud and the large expense of printing and counting ballot papers, several ballot machines or registers have been invented. In that of Vassie there was an arrangement of confluent funnels, by which the voter was prevented from dropping more than one ball into the box. In that of Chamberlain the number of votes given was indicated by the ringing of a bell. In that of Sydserff,[3] the ball was placed by the sheriff in the common duct, and the voter, by moving a lever, guided it into a channel leading to the box of a particular candidate. Generally, it may be said that these mechanical contrivances have been attempts to make the ball-system secret and accurate, each voter depositing a ball, and the accumulated balls showing the state of the poll. This in a large constituency would become unwieldy, and no permanent record of the poll (except the collocation of the balls) would be obtained. A considerable advance is made in the invention of Mr James Davie, Edinburgh, which we select for detailed description. Of this register an essential part is the wooden chamber (4 feet square by 7 feet in height) which the voter, having received a metal ball from the sheriff, enters by a spring-hinged door to which a lever is attached. On one side of the chamber is a box, on the lid of which stand differently coloured cups, marked each with a number and the name of a candidate. Inside the box is a cylinder traversed lengthwise by a spindle, and having at one end a toothed wheel. By a screw-nut the cylinder revolves on and moves along the spindle. On the cylinder is paper divided into spaces, which correspond with the cups, and above this a sheet of carbonised paper as a printing medium. A pinion connects the cylinder with the door-lever, so that the opening of the door drives round the paper one space. A steel type, suspended on an elastic card, is centred to each cup. The voter having placed the ball in a cup, leaves the chamber by another spring-hinged door, which in opening displaces

[1] Hungary is now being divided into equal electoral districts.

[2] On the other hand, by the 2d of the original bye-laws of the Bank of England, it was provided that the ballot should be used in the general courts "in any question *concerning only one person, matter, or thing.*"

[3] Letters-Patent, No. 63 of 1869.

the bottoms of the cups, and thus causes the ball to drop on the head of the type, beneath which it presses against the recording sheet on the cylinder. The ball immediately rolls down a groove to the sheriff's desk outside the chamber, where it is handed to the next voter, *only one ball being used* in connection with each register (unless, of course, there are more votes than one to be given). The closing of the exit door restores the bottoms to the cups. This simple and effectual plan has the merit of secrecy, of immediate detection of fraud (*e.g.*, the introduction of a non-official ball to the cup), of rapidity in voting and in counting, and of leaving almost nothing to the voter's presence of mind. The voter can make only one well defined mark on the paper, and this he can do only in leaving the chamber before the next voter has entered. Mr Davie's invention, which in 1870 received a prize from the Royal Scottish Society of Arts, is obviously not adapted to cumulative voting, but may be worked with any number of candidates under single voting. Although the motion of the cylinder would record in a diagonal direction the series of votes, it would be practically impossible to identify votes from a numbered list of the voters. (W. C. S.)

BALLYCASTLE, a seaport town of Ireland, county Antrim, situated on a bay opposite Rathlin island. The town is well built, consisting of two parts, about a quarter of a mile asunder, and connected by a fine avenue. Towards the close of the 18th century, one of the Boyd family devoted himself to the extension and improvement of the town, establishing manufactures, endowing charities, and building churches, and succeeded in producing a temporary vitality. Upwards of £150,000 is said to have been expended upon the pier and harbour; but the violence of the sea overthrew the former, and the latter has been filled with sand. To the east of the town are the remains of an abbey. Population in 1871, 1253.

BALLYMENA, a town of Ireland, county Antrim, on the Braid, an affluent of the Maine, two miles above their junction. It is 33 miles N.N.W. of Belfast, with which it is connected by railway. The town owes its prosperity chiefly to its linen trade, introduced in 1733, which gives employment to the greater part of the inhabitants. It has a parish church, several chapels and schools, a market-house, and four branch banks. There is a newspaper published in the town called the *Ballymena Observer*. Population in 1871, including Hanyville in the suburbs, 7931.

BALLYSHANNON, a seaport and market-town of Ireland, county of Donegal, situated at the mouth of the Erne. Lat. 54° 30′ N., long. 8° 11′ W. The river is here crossed by a bridge of fourteen arches, which connects the town with the suburb of Purt. Below the bridge the river forms a beautiful cascade, 150 yards wide, with a fall at low water of 16 feet. The harbour is a small creek of Donegal Bay, about 600 yards long and 350 yards broad, and is only accessible to small vessels. The town contains a church, several chapels, a bank, a market-house, barracks, and a union workhouse. The salmon fishery is the only important occupation. Previous to the Union Ballyshannon returned two members to the Irish Parliament. Population in 1871, 2958.

BALMEZ, JAIME LUCIEN, a Spanish ecclesiastic, eminent as a political writer and a philosopher, was born at Vich in Catalonia, on the 28th August 1810, and died there on the 9th July 1848. The most important of his works, and that on which his fame principally rests, is entitled *El Protestantismo comparado con el Catolicismo en sus relaciones con la Civilisacion Europea*, published 1842–44, a most able defence of Catholicism. It has been translated into French, Italian, German, and English. The best of his philosophical works, which are able expositions of the old scholastic system of thought, are the *Filosofia Fondamental*, 1846, and the *Corso de Filosofia Elemental*, 4 vols. 1847. The *Protestantism and Catholicity* and the *Fundamental Philosophy* have both been translated into English (1849, 2 vols. 1857). Nearly all the works are to be had in German and French. See M. de Blanche-Raffin, *Jacques Balmès, sa Vie et ses Ouvrages*, Paris, 1849.

BALMORAL CASTLE, a residence of Her Majesty Queen Victoria, on the right bank of the River Dee, about 9 miles above Ballater and 50 miles from Aberdeen. The property, which now consists of upwards of 10,000 acres, besides a large tract of hill ground, belonged in its original extent to the Farquharsons of Inverey, by whom it was sold to the Earl of Fife. In 1848 it was leased by the late Prince Consort, and in 1852 was finally purchased for a sum of £32,000. The castle, which was erected at Prince Albert's private expense, is of the Scotch baronial style of architecture.

BALNAVES, HENRY, a Scottish Protestant, born at Kirkcaldy in Fife, in the reign of James V., and educated at the university of St Andrews. There is some doubt both as to the exact date of his birth, which has been fixed as 1520, and as to the rank in society to which he belonged. He completed his studies on the Continent, and, returning to Scotland, entered the family of the Earl of Arran, who at that time was regent; but in the year 1542 the earl dismissed him for embracing the Protestant religion. In 1546 he was implicated in the murder of Cardinal Beaton, at least he is known to have taken refuge with the conspirators in the castle of St Andrews; and when they were at last obliged to surrender to the French, he was sent with the rest of the garrison as a prisoner to France. During his confinement at Rouen he wrote the work entitled *Confession of Faith*, to which Knox added marginal notes and a preface; but it was not published till 1584, five years after his death. He returned to Scotland about the year 1559, and having joined the Congregation, was appointed one of the commissioners to treat with the duke of Norfolk on the part of Queen Elizabeth. In 1563 he was made one of the lords of Session, an office which he is said to have held for the first time in 1538, and was appointed by the General Assembly, with other learned men, to revise the *Book of Discipline*. Knox, his contemporary and fellow-labourer, gives him the character of a very learned and pious man. Balnaves died at Edinburgh in 1579.

BALSAM, an oleo-resin or natural compound of resin and essential oil, in such proportions that the substance is in a viscous or semi-fluid condition. The gradations from a solid resin to a limpid essential oil are insensible, and most resins have a balsamic consistency on their exudation, only hardening by exposure to air. It has been proposed to limit the name balsam to such substances as contain cinnamic or an analogous acid in addition to the volatile oil and resin which turpentines contain alone; but this distinction has not been carried out.

The fragrant balsams which contain cinnamic or benzoic acid may, however, be regarded as a distinct class, allied to each other by their composition, properties, and uses. Those of this class found in commerce are the balsam of Peru, balsam of Tolu, liquid storax, and liquidambar. *Balsam of Peru* is the produce of a lofty leguminous tree, *Myrospermum peruiferum*, growing within a limited area in San Salvador, Central America, but now introduced into Ceylon. It is a thick, viscid oleo-resin of a deep brown or black colour and a fragrant balsamic odour. It has been analysed by Kachler, who thus states its percentage composition,—cinnamic acid 46, resin 32, benzylic alcohol 20. It is used in perfumery, and in medicine as a stimulant application to indolent sores, as well as internally for

asthma and pectoral complaints. *Balsam of Tolu* is likewise produced from a species of *Myrospermum*, *M. toluiferum*. It is of a brown colour, thicker than Peru balsam, and attains a considerable degree of solidity on keeping. It also is a product of equatorial America, but is found over a much wider area than is the balsam of Peru. Tolu balsam consists of a combination of inodorous resin with cinnamic acid, no benzoic acid being present in it. It is used in perfumery and as a constituent in cough syrups and lozenges. *Liquid storax* is a balsam yielded by *Liquidambar orientalis*, a native of Asia Minor. It is a soft resinous substance, with a pleasing balsamic odour, especially after it has been kept for some time. It contains a principle—styrol or cinnamene—to which it owes its peculiar odour, besides cinnamic acid, stryacin, and a resin. Liquid storax is used in medicine as an external application in skin diseases, and internally as an expectorant. An analogous substance is derived from *Liquidambar Altingia* in Java. *Liquidambar balsam* is derived from *Liquidambar styraciflua*, a tree found in the United States and Mexico. It contains cinnamic acid, but is destitute of benzoic acid.

Of balsams entirely destitute of cinnamic and benzoic constituents the following are found in commerce :—*Mecca Balsam* or *Balm of Gilead*, yielded by the *Balsamodendron Berryi* (*B. gileadense* of De Candolle), a tree growing in Arabia and Abyssinia, is supposed to be the balm of Scripture and the βάλσαμον of Theophrastus. When fresh it is a viscid fluid, with a penetrating odour, but it solidifies with age. It was regarded with the utmost esteem among the nations of antiquity, and to the present day it is peculiarly prized among the people of the East. *Balsam of Copaiba* or *Capivi* is a fluid oleo resin of a pale brown or straw colour, produced from several trees of the genus *Copaifera*, growing in tropical America. It possesses a peculiar odour and a nauseous persistent tarry taste. Balsam of copaiba contains from 40 to 60 per cent. of essential oil, holding in solution a resin from which capivic acid can be prepared. It is chiefly used in medicine for the treatment of inflammatory affections of mucous surfaces. Under the name of *Wood Oil*, or *Gurjun Balsam*, an oleoresin is procured in India and the Eastern Archipelago from several species of *Dipterocarpus*, chiefly *D. turbinatus*, which has the odour and properties of copaiba, and is used for it in East Indian hospital practice. Wood oil is also used as a varnish in India, and forms an effective protection against the attacks of white ants. A substitute for copaiba is also found in the dark red balsam yielded by *Hardwickia pinnata*, a leguminous tree.

Canada Balsam.—The oleo-resins obtained from coniferous trees are usually termed turpentines, but that yielded by *Abies balsamea* is known in commerce as Balsam of Canada. It is a very transparent substance, somewhat fluid when first run, but thickening considerably with age, possessed of a delicate yellow colour, and a mild terebinthous odour. According to Fluckiger and Hanbury it contains 24 per cent. of essential oil, 60 per cent. of resin soluble in alcohol, and 16 per cent. of resin soluble only in ether. It has been used for the same purposes as copaiba, but its chief uses are for mounting preparations for the microscope and as a varnish.

BALTA, the chief town of a circle of the same name in the Russian government of Podolia. It stands on the Kodima, near its junction with the Bug, and carries on a large trade in cattle and horses and the raw products of the surrounding district. It has two great annual fairs, the more important being held at Whitsuntide and the other in June. A variety of industries, such as tallow-melting, soap-boiling, tile-making, and brewing are likewise prosecuted. The Jews form a very considerable part of the population, which in 1867 numbered 14,528. Balta was in great part destroyed by the Russians in 1780.

BALTARD, Louis Pierre, a distinguished French architect and engraver, was born at Paris in 1765, and died in 1846. He was originally a landscape painter, but in his travels through Italy was so much struck with the beauty of the Italian buildings, that he changed his profession and devoted himself to architecture. In his new occupation he achieved great success, and was selected to prepare the plans for some of the largest public edifices in Paris. His reputation, however, rests not so much on his practical performances in architecture as on his great skill in the art of engraving. Among the best known of his plates are the drawings of Paris (*Paris et ses Monuments*, 2 vols. fol., 1803), the engravings for Denon's *Égypte*, the illustrations of Napoleon's wars (*La Colonne de la grande Armée*), and those contained in the series entitled the *Grand Prix de l'Architecture*, which for some time he carried on alone. He has also gained distinction as an engraver of portraits.

BALTIC SEA. The name by which this inland sea is commonly designated is first found in the 11th century, in the work of Adam of Bremen, entitled *Chorographia Scandinaviæ*.

Sketch Map of Baltic Sea.

The derivation of the word is uncertain. It seems probable that, whatever may be the etymology of the name *Baltic*, that of the Great and Little *Belts* is the same. The Swedes, Danes, and Germans call it the *Ostsee* or East Sea.

The Baltic is enclosed by Sweden, Russia, the German empire, and Denmark ; and it communicates with the North Sea, by the winding channel which lies between the southern part of the Scandinavian peninsula and the northern peninsula of Schleswig and Jutland. The first part of this channel is in great measure blocked by the islands of Zealand and Fünen, so as to form the three narrow passages which are known as the Sound (between

Sweden and Zealand), the Great Belt (between Zealand and Fünen), and the Little Belt (between Funen and Jutland). Each of these forms a distinct communication between the Baltic and the Cattegat, which is the open portion of the channel lying between the coast of Sweden and the eastern side of Jutland; while the Cattegat opens freely into the Skager Rack, which is the continuation of same open channel, between the southern end of Norway and the north-west coast of Jutland, into the North Sea.

The length of the Baltic Sea, from Swinemunde in the S. to Tornea in the N., is nearly 900 miles; and its greatest width, between Karlscrona and Memel, exceeds 200 miles. Its whole area, including the Gulfs of Bothnia and Finland, is about 160,000 geographical square miles. It runs first in an easterly direction as far as Memel, a distance of 300 miles, and then northwards as far as lat. 59° 21′ N., a distance of 350 miles, at which point it separates into two great gulfs. One of these, the Gulf of Finland, runs nearly due E.; the other, the Gulf of Bothnia, almost N. The Gulf of Bothnia is 400 miles in length, with an extreme breadth of 120 miles, but where narrowest it does not exceed 40 miles. The archipelago of Aland lies at its entrance. The Gulf of Finland is 280 miles in length, with a mean breadth of 60 or 70 miles.

The depth of the Baltic rarely exceeds 100 fathoms—being greatest between the island of Bornholm and the coast of Sweden, where it reaches 115 fathoms, and least in the neighbourhood of the mouths of large rivers, which bring down a great quantity of earthy matter, especially in the spring, so that in many parts the bottom is being so rapidly raised by its deposit that the mouths of rivers formerly navigable are now inaccessible. This is especially the case in the northern part of the Gulf of Bothnia, above Quarken, where several tracts are now dry land which were once water; and also in the neighbourhood of Tornea, where meadows now take the place of waters which were traversed in boats by the French Academicians, when they were measuring an arc of the meridian. Along the southern coast the shallowness of the harbours is a great obstacle to navigation, especially since they are closed by ice for nearly one third of the year. On the western side it is not more than 15 fathoms deep; and, in general, it is only from 8 to 10 fathoms. On the S. it nowhere exceeds 50 fathoms. The Gulf of Finland suddenly shallows from 50 or 60 fathoms to 5, or even less. The average depth of the Gulf of Bothnia is not greater than that of the rest of the sea. Numerous rocky islands and reefs, many of them level with the water, render the navigation of this sea extremely dangerous.

The shore of the Baltic is generally low. Along the southern coast it is for the most part sandy,—with sand-banks outside, and sand hills and plains inland. Where streams come down, there are often fresh-water lakes termed *haffs*, which are separated from the sea by narrow spits called *nehrungs*. Two of these *haffs* are of great extent; one of them, termed the Frische Haff, lies between Danzig and Konigsberg, which last town is situated on the part of it most remote from the sea; the other, termed the Kurische Haff, lies between Konigsberg and Memel, the latter town being situated on the channel connecting the haff with the sea. Near the entrance to the Gulf of Finland the coast becomes rocky, and continues to be so for the most part around the gulfs both of Finland and Bothnia, except towards the head of each; the rocks, however, are never high. The shores of the southern part of the Swedish peninsula are mostly high, but not rocky; at Stockholm, however, there is an archipelago of rocky islands, on some of which the town is partly built.

Drainage Area.—The Baltic may be considered as the estuary of a great number of rivers, none of them individually of great size, but collectively draining a very large area, which is estimated at about 717,000 square miles, or nearly one-fifth of the entire area of Europe. This great drainage area is remarkable for the small proportion of its boundary that is formed by mountains or high table-lands,—its greater part consisting of land of no considerable elevation, which slopes down very gradually to its coast-line, and of which a large proportion is covered by lakes. This is especially the character of the drainage area of the Neva, whose waters are immediately derived from the large shallow Lake Ladoga, which receives the contributions of numerous other lakes, Onega being the largest, though Lake Saima in Finland, with its irregular prolongations, is scarcely less extensive. The entire surface drained by the Neva is estimated at about 100,000 square miles, or nearly twenty times that of the drainage area of the Thames. Through Lake Onega, the Neva is connected with the Dwina and the Volga by canals, through which small vessels can pass from the Baltic into either the White Sea or the Caspian. The Duna or South Dwina, which discharges itself into the Gulf of Riga, is another important river, draining an area of about 35,000 miles in West Russia, and having a length of 520 miles, of which 405 miles are navigable. The drainage area of the Niemen, which enters the Baltic at Memel, is conterminous with that of the Duna, and is of about the same extent; this river is navigable for more than 400 miles from its outlet, and communicates with the Dnieper by a canal through which vessels can pass from the Baltic to the Black Sea. The Vistula, which receives the waters of the whole area of Russian and Prussian Poland, flowing past Warsaw into the Baltic at Dantzig, is a very large and important river, having a length of 520 miles, of which 430 are navigable, and a drainage area of 72,000 square miles. And the Oder, rising in the hill districts of Silesia, drains the extensive level areas of Brandenberg and Pomerania, and discharges into an estuary, that may be said to begin from Stettin, the water drawn from an area of 45,000 square miles. Numerous rivers discharge themselves into the Gulf of Bothnia, bringing down water from the mountain ranges of Sweden and Norway; but their course is comparatively short and direct, with few tributaries, so that, individually, they do not attain any great size. The drainage of the more level southern portion of Sweden is for the most part collected by the great lakes Wener, Wetter, and Malar, of which the first pours its water into the North Sea, and the others into the Baltic. By means of a canal joining Lakes Wener and Wetter vessels can pass directly from the Cattegat into the Baltic.

Climate.—It is not only, however, the extent of its drainage area, but the large proportion borne by the rain and snow which fall upon that area to the amount dissipated by evaporation from its surface, that goes to swell the aggregate of fresh water poured into the basin of the Baltic; for there is probably no inhabited region of the whole globe over which so large a quantity of snow falls, in proportion to its area, as it does in the countries round this basin. They receive, direct from the Atlantic, a vast amount of moisture brought by its west and south-west winds; and even the winds which have already passed over the low plains of Jutland and Northern Germany will have parted with little of their moisture before reaching the Baltic provinces of Russia. When these vapour-laden west and south-west winds meet the cold dry east and north-east winds of Siberia, their moisture is precipitated, in summer as rain, and in winter as snow; and owing to the prevalence of a low atmospheric temperature through a large part of the year, the proportion lost by evaporation is extremely small as compared with what passes off from other inland seas. The large excess of the amount of fresh water dis-

charged into the basin, over that which passes off by evaporation from its surface, is indicated by its low salinity, which, however, varies considerably in its different parts and at different seasons of the year. The temperature of the Baltic is remarkable for its *range*, which is rather that of a terrestrial than of a marine area—this being doubtless owing in great degree to the fact that its shallowness and the low salinity of its water allow a large part of its surface to be frozen during the winter. Nearly the whole of the Gulf of Bothnia, with the land enclosing it on both sides, lies between the January isotherms of 10° and 20°—the former crossing it near its head, and the latter near its junction with the Baltic proper; and the whole of the Baltic proper, with the land enclosing it on the east, south, and west, lies between the January isotherms of 20° and 30°. On the other hand, the July isotherm of 60°, which crosses England near the parallel of 54°, passes across the Gulf of Bothnia near the Walgrund Islands, almost 9° further north; and the whole of the Baltic proper, with the Gulf of Finland and the southern part of the Gulf of Bothnia, lies between the July isotherms of 60° and 65°. Thus the range between the *mean summer* and *mean winter* temperatures, which is only about 20° in the British Islands, is about 40° over the Baltic area. The *mean annual* temperature of the Gulf of Bothnia ranges between 30° at its northern extremity and 40° at its southern, while that of the Baltic ranges from 40° at its northern boundary to about 46° at its southern.

Formation and Transportation of Ice.—The greater part of the Gulfs of Bothnia and Finland is usually frozen over during the winter, the formation of ice beginning at the head and extending downwards. Masses of ice, conveyed by the currents into the Baltic proper, freeze together as the winter advances, and form vast fields, generally extending on the east side as far south as the islands of Dagö and Oesel, and on the west to the south of Stockholm. It happens sometimes, though rarely, that large portions of the Baltic proper are continuously frozen over; but navigation is usually interrupted by the blocking up of its bays and harbours with ice, from the latter part of December to the beginning of April. The freezing of the Gulfs of Bothnia and Finland begins earlier and ends later.

The curious phenomenon of *the formation of bottom-ice*, and its rise to the surface, is more frequently seen in the Baltic and the Cattegat than in the open ocean,—chiefly, it seems probable, on account of the shallowness of these seas. It has been particularly observed by Prof. Nilsson in the Cattegat, off Kullen Point, near the southern extremity of Sweden; but according to Chydenius it is very common in various parts of the Baltic, having been especially noticed by the fishermen off the Aland Islands. In calm winter weather, water of from 4 to 8 feet deep is often covered in a very short time with small plates of ice, mostly circular in form, varying in diameter from 1 to 5 inches, and having a uniform thickness which never exceeds two lines. These plates can be seen coming up from below, rising edgeways towards the surface, often with such force as to lift themselves three or four inches out of the water. When they come up in great numbers they are often piled one upon another, and are then usually soon broken, by the action either of waves or of currents, into small pieces, which unite again by regelation so as to form irregular cakes of ice; and these, as soon as the water becomes tolerably still, cohere into a continuous rough sheet. But it sometimes happens that if the plates come up more sparsely, and the weather is very still and cold, they remain unbroken, and the diameter of each increases, sometimes to two feet or even more. When the fishermen notice these ice-plates coming up from below in large quantities, they at once make for land, as they know that they might otherwise be soon completely ice-bound. The same thing appears to happen in polar seas in the shallow water near land. Chydenius, who was a member of the Swedish Spitzbergen expedition in 1857, states that on one occasion the surface of the sea, which was previously quite clear of ice, became so covered in the course of half an hour, that it was with difficulty that a boat could be forced through it; and this although the temperature of the air during the day had not been lower than 4° C., and no wind or stream had brought the ice together.

It does not seem very clear in what way this formation of bottom-ice is to be accounted for. Bottom ice has often been noticed in fresh-water lakes and streams; and large plates have been seen to rise to the surface, sometimes with force enough to bring up stones of considerable size,—in one instance a heavy iron chain. In these cases it would seem that the motion of the bottom-water over roughened surfaces contributes to its congelation. And in the shallow water near the sea-shore, stones and sea-weeds may be seen covered with ice, like the hoar-frost on trees, before any ice forms on the surface. It is to be remembered that *sea-water* increases in density down to its freezing point, so that the water cooled at the surface will always go down, the deepest stratum being thus the coldest. And thus, although no lower temperature can be carried down by the water than that to which it has been subjected at the surface, the water that does not freeze at (say) $-2°{\cdot}5$ C. when lying upon water, changes into ice when it comes in contact with the irregular solid bottom, perhaps on account of the more ready dissipation, under the latter circumstances, of the heat set free in the act of congelation.

When ice forms over the shallow bottoms which border parts of the Gulfs of Bothnia and Finland, large blocks of stone are frequently frozen into it; and these, being lifted when the water rises in the early summer, are often transported by currents to considerable distances, finally subsiding again to the bottom when the ice melts. In this manner a deposit of rocky fragments, some of them 6 or 8 feet across, is being formed at the bottom of the Baltic outlets; as is known from the fact, that sunken ships which have been visited by divers in the Sound and in Copenhagen roads have been found covered with such blocks within no very long period. It not unfrequently happens, moreover, that sheets of ice with included boulders are driven up on the coast during storms, and are thus carried some way inland, being sometimes packed to a height of even 50 feet. A case was described by Von Baer in which a block of granite, whose weight was estimated at between 400 and 500 tons, was thus carried by the ice during the winters of 1837–8; and Forchhammer mentions that the Sound being suddenly frozen over during an intense frost in February 1844, sheets of ice driven by a storm were heaped upon the shore of the bay of Taarbeijk, and frozen into one mass so as to form a mound more than 16 feet high, which threw down the walls of several houses, and left behind it ridges of sand and pebbles when it thawed. It is apparently, moreover, by similar agencies, that the fringe of rocky islands of all dimensions called the *Skar*, which lies at a little distance from the shore of many parts of the Baltic, is being gradually modified. Boats and small vessels can sail in smooth water within this skar, even when the sea outside is strongly agitated; but the navigation is intricate, and the danger from sunken rocks to those not thoroughly acquainted with it is very considerable. The diminution which has been noticed from time to time in the depth of the channels, and the appearance above water of what were formerly regarded as sunken rocks or reefs, have been regarded as concurring with other evidence to prove that a general rise of land is now going on over this area. But it seems probable, from what has

now been stated, that the increase of height and dimensions which has been observed in the reefs and inlets of the skär during the last half century, may be adequately accounted for by the action of ice, which has piled up (generally on a basis of *fixed* rock) accumulations of transported *débris*

Rise of Land around the Baltic.—Early in the last century the Swedish physicist Celsius (to whom we owe the invention of the centigrade scale) formed the opinion that the waters both of the Baltic and of the North Sea were gradually subsiding; and this opinion, though controverted by other authorities, was embraced by Linnæus. It is now clear that many of the facts by which it was supported are explicable by the transporting agency of rivers and of ice, as already explained; and it was pointed out by Playfair in 1802, that even admitting the proofs on which Celsius relied, they would rather show that the land is rising, than that the water is receding. During the present century a great deal of attention has been given to this question, on account of its geological interest, by many very able observers; and the results may be briefly summarised as follows:—(1.) An elevation of the whole of Norway, from the North Cape to the Naze, has taken place within a comparatively recent period,—as is evidenced by the numbers of raised beaches containing existing shells,[1] which are found at different points along the western coast, frequently at a height of 200 feet above the present sea-level, and in some spots at a height of more than 600 feet. As these beaches, where one lies above another, are not always parallel, it appears that the elevatory action did not take place equally over the whole area; and the movements were probably intermittent, with long pauses between. (2.) At various points along the coast of the Baltic and the Gulf of Bothnia, alike in Sweden and in Finland, similar collections of shells have been found, belonging to species now inhabiting the basin, and characterised by the peculiar *facies* to be presently noticed as distinguishing its molluscan fauna from that of the ocean. Such deposits have been found very far inland, and at a height of 230 feet above the sea. Hence it appears that before this upheaval took place, the Baltic must have been separated, as now, from the North Sea by the mountain ridge of Norway, although it extended over a considerably larger area of what is at present low-lying land. (3.) Notwithstanding the numerous observations which have been made with a view to ascertain whether any change of level is now going on, the question must be regarded as still undetermined. Little reliance can be placed on occasional comparisons of the height of marks made upon rocks above the sea-level, since, although there are no tides, the height of the water in the basin is subject to considerable variations, from causes to be presently explained. (4.) There is a good deal of evidence, on the other hand, that, towards the southern extremity of Sweden, there has been a *depression* of the land since the historic period. In this portion, known as Scania, no elevated beds of recent marine shells have been met with; in its seaport towns there are streets now at or even below the level of the water, which must have been above it when first built; and a large stone whose distance from the sea was measured by Linnæus, in 1749, was found 100 feet nearer the water's edge when its distance was again measured in 1836. Near Stockholm, again, a fishing-hut, with remains of boats of very antique form and construction, was found, in 1819, at a depth of 60 feet, covered over with gravel and shell-marl; and it was considered by Sir C. Lyell to be impossible to explain the position of this hut without imagining first a subsidence to the depth of more than 60 feet, and then a re-elevation. On the whole, it appears clear that oscillations of level, not uniform either in direction or in degree, have taken place in various parts of the Scandinavian peninsula within a recent period, whilst in regard to the continuance of any such changes at the present time we have no certain knowledge, though it is considered probable by many of the most distinguished *savans* both of Sweden and Norway.

Movements of Water in the Baltic.—There is scarcely any tidal movement in the Baltic; for though there are sensible tides in the Skager Rack, these begin to diminish in the Cattegat, and are very trifling in the Sound and Belts, averaging only about a foot at Copenhagen. There is usually a general movement of the upper waters of the Baltic towards the three channels which form its outlet, and a considerable flow of water through them. The large volume of water discharged by the rivers that empty themselves into the upper end of that gulf forms a southward current, which becomes very rapid where it narrows at Quarken (being partly blocked also by the Walgrund Islands), and again where it is obstructed by the Aland Islands, as it enters the Baltic proper. In that part of the basin the current is liable to considerable modification from prevalent winds; but it is usually very perceptible in the spring and early part of the summer, when the snows are melting. On the other hand, when an unusual continuance of north-west wind concurs with high spring-tides to drive the water of the North Sea into the outlet of the Baltic, a large body of water flows back into its basin, producing a reverse current, which is felt as far as Danzig.

There are also considerable variations in the height of the water, that seem for the most part referrible to three different conditions, which may operate separately or in combination, viz., (1), the seasonal increase and decrease of the amount of water brought down by rivers; (2), the banking-up of the outflow by opposing winds; and (3), variations in atmospheric pressure.

(1.) During the winter months the quantity of fresh water poured into the Baltic by the rivers which discharge themselves into it is greatly reduced by the freezing of their sources; and this is, of course, especially the case with those that empty themselves into the Gulf of Bothnia. Hence the general level of the surface is at its lowest at this season. With the melting of the snow in spring and early summer, however, there is an enormous increase in the quantity of fresh water poured into the basin, and the level of its surface then rises. There is always, of course, a tendency to equalisation of the level of the Baltic with that of the sea outside, by outflow or inflow currents through its three channels of communication; but the narrowness of these prevents that equalisation from being immediate, and it is often interfered with by winds. (2.) The influence of winds in banking up the water at the outlets, and even in reversing the usual currents, is very decided, as has been especially shown by the recent researches of Dr Meyer of Kiel.[2] The strongest and most constant surface-outflow is seen during the autumn and winter months, when there is little or no elevation of level, but when the prevalent direction of the wind is such as to drive the Baltic water towards and through the straits. When, on the other hand, the winds prevalent in the North Sea tend to drive its water into the straits, their usual outcurrent may be reversed; and this most frequently happens during the spring and summer months, although the excess

[1] The shells found in the raised beach at Uddevalla by Mr J. Gwyn Jeffreys in 1862, were characterised by him as glacial; but they have been shown to be specifically identical with mollusca now living at Spitzbergen; and it is probable that when the water was deeper than at present along the coast of Norway, these would have ranged southwards along the cold bottom, as they do even now to a certain extent.

[2] *Untersuchungen über Physikalische Verhältnisse des Westlichen Theiles der Ostsee.*

water to be discharged is then at its greatest. It sometimes happens, especially about the autumnal equinox, that a N.W. gale concurs with a high tide in the Skager Rack to drive its waters towards the Baltic, causing it to overflow the lower portions of some of the Danish islands. If, then, a southerly wind should carry this water onwards into the Gulf of Finland, the check which it gives to the downflow of the Neva produces disastrous inundations at St Petersburg. (3.) The influence of atmospheric pressure upon the height of the water in the Baltic is very remarkable. It had long been noticed that its level occasionally rises even as much as 3 feet without any apparent cause, and maintains itself at that height, sometimes only for a few days, but occasionally for several weeks together, and this at all seasons. Schultén, having observed that such elevations of level are preceded by a fall of the barometer, and that when the barometer rises again the water subsides, was led to recognise the dependence of these changes upon converse changes in atmospheric pressure; and this reference was confirmed by observation of the constant proportion borne by one to the other. A similar consequence of variation in atmospheric pressure has been observed in the Mediterranean (see MEDITERRANEAN); and it has also been noticed in England as a disturbing element in modifying the height of the tides.

Salinity of Baltic Water.—As might be expected from what has been already stated, the proportion of salt in the water of the Baltic is very much below that of oceanic water, and varies greatly at different seasons. In the Gulf of Bothnia, at the time the river-flow is greatest, the surface water is often so little salt as to be quite drinkable, its sp. gr. having been found as low as 1·004. But it is said to contain at Christmas six times as much salt as at midsummer, showing that when the river supply is at its lowest, its place is taken by a reflux of salt water from the outside ocean. In the Baltic proper there is a very decided difference in salinity between the upper and the lower stratum; the less saline water of the surface flowing towards the outlet over the more saline water beneath, just as the fresh-water current of a great river runs out to sea, even far beyond the sight of land. Thus the proportion of salt in 1000 parts of a sample of *surface*-water taken near Stockholm being 5·919, that of *bottom*-water, brought up from 120 fathoms, was 7·182; and in like manner the proportion of salt in *surface*-water at the entrance of the Gulf of Finland being 3·552, that of *bottom*-water at 30 fathoms depth was 4·921,—the proportion of salt in North Sea water averaging 32·823 parts in 1000. Nearer the outlet the proportion of salt is greater alike in surface and in bottom-water. From the careful and systematic observations of Dr Meyer (*op. cit.*), it appears that the sp. gr. of the surface-stratum at Kiel ranges between about 1·0082 in summer and 1·0142 in winter, the latter showing somewhat above half the quantity of salt contained in ordinary sea-water. But if the direction of the prevalent winds during the autumn be such as to maintain a strong surface out-current, and consequently (as will presently appear) a very strong inward under-current, as happens in some years, the maximum of salinity will present itself at that season. The sp. gr. of the deeper stratum ranges at Kiel from 1·0145 to 1·0190; at Helsingör on the Sound from 1·0190 to 1·0220; and at Korsor on the Great Belt from 1·0180 to 1·0213; thus showing it to be principally composed of North Sea water, whose sp. gr. may be taken as 1·0264.

Currents in the Baltic Straits.—The results of observation of the movements of the upper and under strata of water in the Baltic Straits, strongly confirm the doctrine elsewhere enunciated (see ATLANTIC) in regard to the potency of slight differences of downward pressure in the production of under-currents. The prevalent movement of the upper stratum in the Baltic Straits is *outward*; and this concurs with the low salinity of Baltic water to indicate that it is partly an *overflow* current, produced by the excess of river supply over loss by evaporation, which tends to raise its level. But even when this *outward* surface-current is strong, there is usually an *inward* under-current of North Sea water, carrying back into the basin of the Baltic a large proportion of the salt which would otherwise be lost to it; and the existence of this under-current, which has been abundantly established by experimental inquiries, as well as by the observations of divers, is exactly what theory would lead us to predict. For if two columns of water of the same height, but differing in specific gravity, be made to communicate with each other alike at the surface and at the bottom, the lower part of the heavier column, having a greater lateral pressure, will flow towards the lighter, thus tending to produce an elevation of level in the latter, which will rectify itself by a surface-flow in the opposite direction; and thus a vertical circulation will be maintained, as long as the causes which maintain the difference of salinity remain in operation. Now, as the salinity in the oceanic column may be regarded as practically constant, whilst the salinity of the Baltic column, though not uniform, is kept down by the influx of river-water to a much lower degree, this difference will always exist to a greater or less amount. When, however, the height of the Baltic column is so much raised—either by the excess of its fresh-water supply, or by the reversal of the surface-current by the agency of wind—that the downward pressure of its less saline water exceeds that of the more saline water of the North Sea column, the under-current will be brought to a stand, or its direction will be reversed. Thus it is that when the outward movement of the upper stratum depends rather upon the prevalent winds (as is usually the case during autumn and winter) than upon the elevation of its level within the basin, the inward under-current which supplies its place is strongest and most constant. And it is by this means, much more than by the occasional reversal of the surface-current, that salt is carried back into the Baltic, as is proved by the close correspondence shown by Dr Meyer's observations to exist between the predominance of the inward under-current and the elevation of the sp. gr. of the surface-water of the Baltic. On the other hand, it is during the spring and summer months, when the outward movement of the upper stratum is rather an overflow-current, and the salinity of the surface-water is the lowest, that the under-current sets less strongly and less constantly inward.

Zoology. The fauna of the Baltic may be regarded as that of a large estuary, having a narrow communication with the sea,—its marine inhabitants being such as can adapt themselves to considerable variations in the salinity of its water. Whales rarely enter the Baltic; but porpoises frequent the neighbourhood of the Danish islands. Seals are obtained in considerable numbers at the breaking up of the ice around Gottland and the Aland Isles. The salmon is among the most abundant fishes of the Baltic proper, ascending its rivers from April to June; and salmon-trout are caught in some of its bays. The portion of the Baltic in the neighbourhood of the Danish islands is frequented by various species of *Gadidæ*, which do not range further east. In the 14th and 15th centuries there was a considerable herring-fishery within the Sound and along the coast of Scania (the southern portion of Sweden); but this fish seems to have latterly quite deserted the Baltic, and rarely shows itself even in the Cattegat. On the eastern coast of Sweden, on the other hand, and in the Gulf of Bothnia, a fish called the strömling, which is nearly allied to the herring, being chiefly distinguished by its small size, is

caught in great numbers, and is dried and salted for distant markets. The molluscan fauna of the Baltic is chiefly made up of common shells of our own shores,—such as *Cardium*, *Mytilus*, and *Littorina*, which can bear an admixture of fresh water, together with several proper fresh-water shells, such as *Paludina*, *Neritina*, and *Lymnæa*; the marine types, however, being remarkable for their very small size, which is often not above one-third of their usual dimensions. There is an entire absence, except in the neighbourhood of the straits, of such essentially marine types as *Buccinum*, *Ostrea*, *Pecten*, *Patella*, and *Balanus*. It is interesting to remark that the Danish *Kjokkenmodding* contain abundance of oysters, and also of full-sized cockles, mussels, and periwinkles; from which it may be inferred that even within the human period the outside ocean had freer access to the basin of the Baltic than it has now,—probably through what is now the peninsula of Jutland, which seems at no remote period to have been an archipelago. (W. B. C.)

BALTIMORE, in Maryland, one of the largest and most flourishing cities in the United States of North America, is situated on the north side of the Patapsco River or Bay, 14 miles above its entrance into the Chesapeake, 37 miles N.E. of Washington, and 100 S.W. of Philadelphia. Lat.

39° 17′ N., long. 76° 36′ W. The natural advantages of this position were long overlooked by the settlers in the vicinity of the Chesapeake; and it was only in 1729 that they directed their attention to the place, and laid out a plan of the town. At that time a part of it was under cultivation as a farm, but all the rest was a wilderness. For some years its growth was by no means rapid, as it had to contend with all the obstacles that could be thrown in its way by the jealousy of older rivals. From an authentic sketch of Baltimore made in the year 1752, it appears that it then contained about twenty-five houses, only four of which were built of brick, the rest being of a more primitive structure. In 1768 it became the county town; and in 1775, according to a census then taken, it contained 564 houses, and 5934 inhabitants. From this time it rose rapidly into importance; and in 1780 became a port of entry, when a custom-house was opened. Previous to this all vessels trading to and from the port had to be entered, cleared, and registered at Annapolis. In December 1796 it obtained an act of incorporation. By the census of 1870 Baltimore contained 267,854 inhabitants.

The city is pleasantly situated on slightly undulating ground, and extends about 4½ miles from E. to W., and 3½ from N. to S., covering an area of 10,000 acres. It is divided into two nearly equal parts by a small stream called Jones's Falls, crossed by a number of bridges. The division east of the falls is nominally subdivided into two parts—Fell's Point and Old Town. The former, the most easterly part of the town, is the principal resort of seamen, and is the place where the shipbuilding and manufactures are principally carried on. The Old Town lies to the N. and W. of this. The portion west of the Falls is likewise divided into two parts, the city proper and Spring Garden. The former is the centre of trade, and the residence of the more wealthy inhabitants; while the latter, which is the extreme south-western quarter, and the lowest and most unhealthy portion of the city, is inhabited by the poorer classes. Baltimore contains about 200 churches, and has **Buildings** three universities, several colleges, 122 public schools, a state normal school, a manual labour school, besides numerous private schools and academies, an academy of art and science, an infirmary, hospitals, asylums, dispensaries, &c., three theatres, an opera-house, a museum, and many fine public buildings. The most imposing building in the city is the new city hall, one of the finest structures of the kind in the country. It occupies an entire square of ground, an area of about 26,000 square feet, near the centre of the city, and contains the various municipal offices. The style of architecture is the Renaissance, of which it is a fine specimen. The entire outer facing of the walls, the portico, and all the ornamental work, are of white Maryland marble; the inner walls and floors are of brick, and are fire-proof. It is four stories high, surmounted by a Mansard roof of iron and slate, with a dome and tower of iron on a marble base, rising to the height of 240 feet. The interior is very finely finished. It was begun in 1867, and cost about $2,600,000. Another important public building is that of the Peabody Institute, founded by the late George Peabody, Esq., of London, and endowed by him to the amount of $1,400,000. It has provisions for a public library, a gallery of art, and a conservatory of music, also for lectures and musical performances. It was incorporated in 1857. One wing of the building, which is immediately contiguous to the Washington monument, is completed, and the remainder is in progress. The completed wing is faced and ornamented with white marble, in a simple but massive and imposing style, and contains the library of over 56,000 volumes (1875), and a hall for lectures, concerts, &c. The custom-house is a spacious building, 225 feet long, by 141 feet wide. The principal room is 53 feet square, and is lighted by a dome 115 feet above the street. On its four sides are colonnades, the columns of which are each a single block of fine Italian marble. Baltimore has several splen- **Monuments** did monuments, which have acquired for it the name of "the Monumental City." The largest of these, erected to the memory of Washington, stands on an eminence of 150 feet, and has, with its base, an altitude of 200 feet. It is of white marble; the base is 50 feet square, and 24 feet in height, surmounted by a Doric column 25 feet in diameter at the base, with a spiral staircase in its interior, and on the summit is a statue of Washington, 13 feet high. The "Battle Monument," also of white marble, was erected by public subscription in 1815, to the memory of those who had fallen in defence of the city in the previous year. It is 52 feet high; the base is of Egyptian architecture; the column is in the form of a bundle of Roman fasces, upon the bands of which are inscribed the names of those whom it commemorates; and the whole is surmounted by a female figure, the emblematical genius of the city. The city

Water-supply. is supplied with water from Lake Roland, an artificial lake about 8 miles north of the city, of a capacity of 500,000,000 gallons, and from three other reservoirs, with an aggregate storage capacity of about 580,000,000 gallons, the common source of supply being Jones's Falls. There are also numerous public springs and fountains throughout **Parks.** the town. Baltimore has a number of parks and public squares, chief of which is Druid Hill Park, a tract of 700 acres on the extreme north-west of the city, possessing more natural beauties than any other in the United States.

Industries. The manufactures and commerce of Baltimore are very extensive and flourishing. There is scarcely a branch of industry that is not prosecuted to some extent in the city or its vicinity. Among these are shipbuilding, iron and copper works, woollen and cotton manufactures, pottery, sugar-refining, petroleum-refining, distilling, saddlery, agricultural implement-making, cabinet-making, tanning, &c. In the vicinity of Baltimore is found the finest brick-clay in the world, of which more than 100,000,000 bricks are made annually. The Abbott Iron-works, in the eastern part of the city, have the largest rolling-mills in the United States. An industry peculiar to Baltimore is the packing of oysters in air-tight cans for shipment to all parts of the world. The oysters are taken in the Chesapeake Bay. Fruits and vegetables are also packed in the same way, the entire trade consuming from twenty to thirty million cans annually. This city is one of the greatest flour-markets in the Union, and has a large export trade in tobacco. There belonged to the port of Baltimore (30th November 1874) 834 vessels, registering 84,900 tons, of which 66 vessels (22,000 tons) were engaged in foreign, and the rest in the coasting trade. These figures show a considerable reduction from those of 1860, as a result of the war between the States, during which many Baltimore vessels were enrolled under foreign flags, and have so remained. There are twenty-six banks, with a capital (in 1874) of $11,000,000, and seven savings banks; seventeen fire and marine and three life insurance companies, besides many agencies for other companies. The assessed value of taxable property of all kinds in Baltimore for the year 1870 was $207,181,550, and for the year 1875, $231,242,313, being an increase of $24,060,763. The harbour, which **Harbour.** consists of three parts, is excellent. Its entrance, between Fort M'Henry and the lazaretto, is about 600 yards wide, with 23 feet of water. This depth is continued with an increased width for a mile and a quarter, to near Fell's Point. The entrance to the second harbour is opposite Fell's Point, where the width is contracted to one-fourth of a mile, with a depth of 16 feet. Above this entrance it widens into an ellipse of a mile long, half a mile broad, and 15 feet deep. The third, or inner harbour, has a depth of 14 feet, and penetrates to near the centre of the city. Vessels of the largest class can lie at the wharves near Fell's Point, Locust Point, and Canton, and those of 500 tons can come into the inner harbour. The harbour **Railways.** is defended by Fort M'Henry. The railroads of Baltimore are,—The Philadelphia, Wilmington, and Baltimore line, opened in 1837, length 98 miles; the Northern Central, to Sunbury in Pennsylvania, completed in 1858, length 138 miles; the Baltimore and Potomac to the Potomac River, opened in 1873, length 73 miles, with a branch to Washington (on this road there is a tunnel a mile and three-quarters in length); the Baltimore and Ohio, the main stem of which goes to Wheeling, a distance of 379 miles, opened through in 1853. It has the Parkersburg Division, 104 miles; the Central Ohio Division, to Columbus, 513 miles from Baltimore; and the Lake Erie Division to Chicago, opened in 1874, 878 miles. The city is also traversed by numerous lines of horse-railways for the convenience of local travel. In healthfulness Baltimore is the fourth city in the Union, its annual death-rate being ·025. Its mean annual temperature is 56° Fahr.; the mean summer and winter temperatures 76° and 36° respectively.

BALUCHISTAN, a maritime country of Asia, whose coast is continuous with that of the north-western part of the Indian Peninsula. It is bounded on the N. by Afghanistan, on the E. by Sindh, on the S. by the Arabian Sea, and on the W. by Persia. The frontier between Persia and Baluchistan has been drawn by an English commission, sent out in 1870 under Sir F. Goldsmid, from Gwadur Bay (about 61° 36′ E. long.) northwards, to lat. 26° 15′ N., when it turns eastward to the Nihing River, following which N. and E. to its sources, it passes on to about 63° 12′ E. long., when it resumes a northerly direction to Jalk. As thus determined, Baluchistan has an area of about 106,500 sq. miles. It extends from lat. 24° 50′ to 30° 20′, and from long. 61° 10′ to 68° 38′; its extreme length from E. to W. being 500 miles, and its breadth 370.

The outline of the sea-coast is in general remarkably regular, running nearly due E. and W., a little N. of lat. 24° 16′ from Cape Monze, on the border of Sindh, to Cape Jewnee, near the River Dustee. It is for the most part craggy, but not remarkably elevated, and has in some places, for a considerable distance, a low sandy shore, though almost everywhere the surface becomes much higher inland. The principal headlands, proceeding from E. to W., are Cape Monze or Ras Moarree, which is the eastern headland of Sonmeanee Bay; Goorab Sing; Ras Arubah; Ras Noo, forming the western headland of Gwadel Bay; Ras Jewnee, forming the eastern point of Gwadur Bay, and Cape Zegin

Sketch Map of Baluchistan.

at its western extremity. There is no good harbour along the coast, though it extends about 600 miles; but there are several roadsteads with good holding-ground, and sheltered on several points. Of these the best are Sonmeanee Bay, Homara, and Gwadur. On the latter are situated a small town and a fort of the same name, and also a telegraph station of the Indo-European line.

Of the early history of this portion of the Asiatic continent little or nothing is known. The poverty and natural strength of the country, combined with the ferocious habits of the natives, seem to have equally repelled the friendly visits of

inquisitive strangers and the hostile incursions of invading armies. The first distinct account which we have is from Arrian, who, with his usual brevity and severe veracity, narrates the march of Alexander through this region, which he calls the country of the Oritæ and Gadrosii. He gives a very accurate account of this forlorn tract, its general aridity, and the necessity of obtaining water by digging in the beds of torrents; describes the food of the inhabitants as dates and fish; and adverts to the occasional occurrence of fertile spots, the abundance of aromatic and thorny shrubs and fragrant plants, and the violence of the monsoon in the western part of Mekran. He notices also the impossibility of subsisting a large army, and the consequent destruction of the greater part of the men and beasts which accompanied the expedition of Alexander. At the commencement of the 8th century this country was traversed by an army of the caliphate.

The country derives its name from the Baluches, but the Brahoes are considered the dominant race, from which the ruler of the country is always selected. From whatever quarter these may have arrived, they eventually expelled, under their leader Kumbur, the Hindu dynasty, which at that time governed the country, and conquered Baluchistan for themselves. The Baluches are a quite distinct race, and must have arrived in the country at a subsequent period, probably in small bodies, some of which may have come from Syria or from Arabia; in proof of this the Kyheree, for instance, possess a remarkably handsome breed of horses showing unmistakable Arab blood. Anyhow, so marked is the social distinction between Baluch and Brahoe, that when the khan assembles his forces for war the latter tribes demand, as their right, wheaten flour as a portion of their daily rations, while the Baluch tribes are only entitled to receive that made from a coarse grain called jowar. There is also a Persian colony known as the Dehwars; and a considerable number of Hindus, who appear to have been the first settlers in the Brahoe mountains on their expulsion from Sindh, Lus, and Mekran by the caliphs of Baghdad.

Taking a general view on the subject of the original inhabitants of Baluchistan, we may conclude that they have, from a very early date, been reinforced by emigration from other countries, and from stragglers dropped from the hosts of the numerous conquerors, from Alexander to Nadir Shah, who have passed and repassed through Baluchistan or its neighbourhood on their way to and from India. Thus we find the Saka tribe located on the plains of Gressia, on the borders of Mekran, the ancient Gedrosia, and still further to the west, the Dahoe. These tribes are on the direct line of Alexander's march; and we know that tribes of this name from the shores of the Caspian accompanied his army. In Sarawan we find the Sirperra, and Pliny tells us that a tribe called Saraparæ resided near the Oxus. Further, on the Dushti be doulets, a plain at the northern entrance of the Bolan Pass, we find the Kurds, a name, again, familiar as that of a celebrated and ancient nation. The names of numerous other tribes might be cited to support this view, but it would require too much space to follow up the subject. Both Brahoes and Baluches are Mahometans of the Suni persuasion.

The precise period at which the Brahoes gained the mastery cannot be accurately ascertained; but it was probably about two centuries ago. The last rajah of the Hindu dynasty found himself compelled to call for the assistance of the mountain shepherds, with their leader, Kumbur, in order to check the encroachments of a horde of depredators, headed by an Afghan chief, who infested the country, and even threatened to attack the seat of government. Kumbur successfully performed the service for which he had been engaged; but having in a few years quelled the robbers, against whom he had been called in, and finding himself at the head of the only military tribe in the country, he formally deposed the rajah and assumed the government.

The history of the country after the accession of Kumbur is as obscure as during the Hindu dynasty. It would appear, however, that the sceptre was quietly transmitted to Abdulla Khan, the fourth in descent from Kumbur, who, being an intrepid and ambitious soldier, turned his thoughts towards the conquest of Cutch-Gundava, then held by different petty chiefs, under the authority of the Nawabs of Sindh.

After various success, the Kumburanees at length possessed themselves of the sovereignty of a considerable portion of that fruitful plain, including the chief town, Gundava. It was during this contest that the famous Nadir Shah advanced from Persia to the invasion of Hindustan; and while at Kandahar, he despatched several detachments into Baluchistan, and established his authority in that province. Abdulla Khan, however, was continued in the government of the country by Nadir's orders; but he was soon after killed in a battle with the forces of the Nawabs of Sindh. He was succeeded by his eldest son, Hajee Mohummud Khan, who abandoned himself to the most tyrannical and licentious way of life, and alienated his subjects by oppressive taxation. In these circumstances Nusseer Khan, the second son of Abdulla Khan, who had accompanied the victorious Nadir to Delhi, and acquired the favour and confidence of that monarch, returned to Khelat, and was hailed by the whole population as their deliverer. Finding that expostulation had no effect upon his brother, he one day entered his apartment and stabbed him to the heart. As soon as the tyrant was dead, Nusseer Khan mounted the *musnud*, amidst the universal joy of his subjects; and immediately transmitted a report of the events which had taken place to Nadir Shah, who was then encamped near Kandahar. The shah received the intelligence with satisfaction, and despatched a firman, by return of the messenger, appointing Nusseer Khan beglerbey of all Baluchistan. This event took place in the year 1739.

Nusseer Khan proved an active, politic, and warlike prince. He took great pains to re-establish the internal government of all the provinces in his dominions, and improved and fortified the city of Khelat. On the death of Nadir Shah in 1747, he acknowledged the title of the king of Cabul, Ahmed Shah Abdulla. In 1758 he declared himself entirely independent; upon which Ahmed Shah despatched a force against him, under one of his ministers. The khan, however, raised an army and totally routed the Afghan army. On receiving intelligence of this discomfiture, the king himself marched with strong reinforcements, and a pitched battle was fought, in which Nusseer Khan was worsted. He retired in good order to Khelat, whither he was followed by the victor, who invested the place with his whole army. The khan made a vigorous defence; and, after the royal troops had been foiled in their attempts to take the city by storm or surprise, a negotiation was proposed by the king, which terminated in a treaty of peace. By this treaty it was stipulated that the king was to receive the cousin of Nusseer Khan in marriage; and that the khan was to pay no tribute, but only, when called upon, to furnish troops to assist the armies, for which he was to receive an allowance in cash equal to half their pay. The khan frequently distinguished himself in the subsequent wars of Cabul; and, as a reward for his services, the king bestowed upon him several districts in perpetual and entire sovereignty. Having succeeded in quelling a dangerous rebellion, headed by his cousin Beheram Khan, this able prince at length died in extreme old age, in the month of June 1795, leaving three sons and five daughters. He

was succeeded by his eldest son Muhmood Khan, then a boy of about fourteen years. During the reign of this prince, who has been described as a very humane and indolent man, the country was distracted by sanguinary broils; the governors of several provinces and districts withdrew their allegiance; and the dominions of the khans of Khelat gradually so diminished, that they now comprehend only a small portion of the provinces formerly subject to Nusseer Khan.

In 1839, when the British army advanced through the Bolan Pass towards Afghanistan, the conduct of Mehrab Khan, the ruler of Baluchistan, was considered so treacherous and dangerous, as to require "the exaction of retribution from that chieftain," and "the execution of such arrangements as would establish future security in that quarter." General Willshire was accordingly detached from the army of the Indus with 1050 men to assault Khelat. A gate was knocked in by the field-pieces, and the town and citadel were stormed in a few minutes. Above 400 Baluches were slain, among them Mehrab Khan himself; and 2000 prisoners were taken. Subsequent inquiries have, however, proved that the treachery towards the British was not on the part of Mehrab Khan, but on that of his vizier, Mahomed Hassein, and certain chiefs with whom he was in league, and at whose instigation the British convoys were plundered in their passage through Cutch-Gundava and in the Bolan Pass. The treacherous vizier, however, made our too credulous political officers believe that Mehrab Khan was to blame,—his object being to bring his master to ruin and to obtain for himself all power in the state, knowing that Mehrab's successor was only a child. How far he succeeded in his object history has shown. In the following year Khelat changed hands, the governor established by the British, together with a feeble garrison, being overpowered. At the close of the same year it was reoccupied by the British under General Nott. In 1841, Nusseer Khan, the youthful son of the slain Mehrab Khan, was recognized by the British, who soon after evacuated the country.

From the conquest of Sindh by the British troops under the command of the late General Sir Charles Napier in 1843 up to 1854, no diplomatic intercourse occurred worthy of note between the British and Baluch states. In the latter year, however, under the governor-generalship of the late marquis of Dalhousie, the late General John Jacob, C.B., at the time political superintendent and commandant on the Sindh frontier, was deputed to arrange and conclude a treaty between the Khelat state, then under the chieftainship of Meer Nusseer Khan, and the British Government. This treaty was executed on the 14th of May 1854, and was to the following effect:-

"That the former offensive and defensive treaty, concluded in 1841 by Major Outram between the British Government and Meer Nusseer Khan, chief of Khelat, was to be annulled.

"That Meer Nusseer Khan, his heirs and successors, bound themselves to oppose to the utmost all the enemies of the British Government, and in all cases to act in subordinate co-operation with that Government, and to enter into no negotiations with other states without its consent.

"That should it be deemed necessary to station British troops in any part of the territory of Khelat, they shall occupy such positions as may be thought advisable by the British authorities.

"That the Baluch chief was to prevent all plundering on the part of his subjects within, or in the neighbourhood of, British territory.

"That he was further to protect all merchants passing through his territory, and only to exact from them a transit duty, fixed by schedule attached to the treaty; and that, on condition of a faithful performance of these duties, he was to receive from the British Government an annual subsidy of 50,000 rupees (£5000)."

The provisions of the above treaty were most loyally performed by Meer Nusseer Khan up to the time of his death in 1856. He was succeeded by his brother, Meer Khodadad Khan, the present ruler, a youth of twelve years of age, who, however, did not obtain his position before he had put down by force a rebellion on the part of his turbulent chiefs, who had first elected him, but, not receiving what they considered an adequate reward from his treasury, sought to depose him in favour of his cousin Shere dil Khan. In the latter part of 1857, the Indian rebellion being at its height, and the city of Delhi still in the hands of the rebels, a British officer (Major Henry Green) was deputed, on the part of the British Government, to reside, as political agent, with the khan at Khelat, and to assist him by his advice in maintaining control over his turbulent tribes. This duty was successfully performed until 1863, when, during the temporary absence of Major Malcolm Green, the then political agent, Khodadad Khan was, at the instigation of some of his principal chiefs, attacked, while out riding, by his cousin, Shere dil Khan, and severely wounded. Khodadad fled in safety to a residence close to the British border, and Shere dil Khan was elected and proclaimed khan. His rule was, however, a short one, for, early in 1864, when proceeding to Khelat, he was murdered in the Gundava Pass; and Khodadad was again elected chief by the very men who had only the previous year caused his overthrow, and who had lately been accomplices to the murder of his cousin. Since the above events Khodadad has maintained his precarious position with great difficulty; but owing to his inability to govern his unruly subjects without material assistance from the British Government, which they are not disposed to give, his country has gradually fallen into the greatest anarchy; and, consequently, some of the provisions of the treaty of 1854 having been broken, diplomatic relations have been discontinued with the Khelat state since the end of 1874.

The territories of Baluchistan are now comprised under the following divisions—Jalawan, Sarawan, Khelat, Mekran, Lus, Cutch-Gundava, and Kohistan.

The most remarkable features of this extensive country are its rugged and elevated surface, its barrenness, and its deficiency of water. The mass of mountains which forms the eastern boundary of that division of Baluchistan called the Kohistan, or mountain territory, lying between the capital, Khelat (lat. 29° 1′ 38″ N., long. about 66° 39′ E.), and the plain country to the east of it, designated Cutchee, or Cutch-Gundava, is composed of several parallel ranges of limestone rock, in close proximity to each other, having a general strike of N.N.E. to S.S.W and a breadth of about 55 miles. This range originates in Afghanistan, and enters Baluchistan north of the Bolan Pass in about 30′ N. lat. and about 60° 30′ E. long. under the name Herbooe; and, after throwing out a branch to the eastward, which touches the River Indus at Sehwan, terminates under the designation of the Hala Mountains, at Cape Monze on the coast of the Arabian Sea, W. of Kurrachee, in about 25° N. lat. and 66° 68′ E. long., thus having a total length of upwards of 300 miles. The highest mountain of this range is the Chehil Tan, bearing about N. by E., 85 miles from Khelat, and attaining an altitude of 12,000 feet above the sea. The western range of the Herbooe Mountains in this portion of Baluchistan are barren and without timber, and scantily peopled with pastoral tribes of Brahoes, who emigrate to the plains of Cutchee on the approach of the winter months.

North of the Bolan River and Pass the Herbooe Mountains are met, in about lat. N. 30°, by confused ranges

of rough precipitous mountains, which extend to the eastward with a strike nearly E. and W. to the Sooliman range, in about 29° 5′ N. lat. and about 69° 30′ E. long. This tract is almost entirely inhabited by Murrees, Boogtees, and other tribes of Baluch plunderers, and is bounded on the N. by the province of Sewestan. South of these ranges lies the desert country, which touches the Sindh frontier in 28° 27′ N. lat.

The two principal water courses which drain the Kohistan portion of Baluchistan E. of Khelat are the rivers Bolan and Moola, the former rising about 60 miles N.E. of Khelat, the latter at Anjeera, lat. 28° 19′ N., long. about 66° 29′ E., about 45 miles south of that city. They both discharge themselves into the plains of Cutchee, the former at Dadur, lat. about 29° 28′ 51″ N., long. about 67° 26′ E., and the latter at Kotra near Gundava, lat. 28° 33′ 47″ N., long. about 67° 26′ E. There is at all seasons a plentiful supply of clear running water in these streams, which is entirely used up for irrigational purposes on issuing into the plains. They are subject to dangerous floods from sudden storms in the neighbouring mountains during the rainy season. The two easiest and safest passes from Central Asia into India take their names from these streams. South of the Moola the Gaj River issues into the plains, and its waters are also absorbed in cultivation. The Nara issues into the plains near Kujjuk, N.W. corner of Cutch-Gundava, in lat. about 29° 36′ N., and long. about 68° 2′ E.; ordinarily its water is utilized entirely for cultivation in its course through the Afghan province of Seebee; but at periods of heavy rains in the mountains it is liable to burst its banks, and then inundates immense tracts in the Cutchee desert to the south.

West of Khelat, as far as about 65° 30′ E. long., the mountain ranges have much the same strike, and are of the same nature as those to the eastward, but the ranges are much narrower, more defined, and of a lower altitude. The valleys between them vary from 5 to 15 miles in breadth; they are quite devoid of trees. The water-courses generally follow the direction of the hills from N. to S. and in some instances during heavy rains their waters reach the Arabian Sea; but as a general rule they are absorbed long before they reach the coast, partly in cultivation, but principally by the sandy arid nature of the soil and excessive dryness of the atmosphere, due, probably, to the proximity of the great desert west of Kharan, which extends to the confines of Persia. The most important of these water-courses is the Dustee or Mooleance.

The climate of Baluchistan is extremely various in the different provinces. The soil in general is exceedingly stony. In the province of Cutch-Gundava, however, it is rich and loamy, and so very productive, that, it is said, were it all properly cultivated, the crops would be more than sufficient for the supply of the whole of Baluchistan. Gold, silver, lead, iron, tin, antimony, brimstone, alum, sal-ammoniac, and many kinds of mineral salts, and saltpetre, are found in various parts of the country. The precious metals have only been discovered in working for iron and lead, in mines near the town of Nal, about 150 miles S.S.W. of Khelat. The different other minerals above enumerated are very plentiful. The gardens of Khelat produce many sorts of fruit, which are sold at a very moderate rate, such as apricots, peaches, grapes, almonds, pistachio nuts, apples, pears, plums, currants, cherries, quinces, figs, pomegranates, mulberries, plantains, melons, guavas, &c. All kinds of grain known in India are cultivated in the different provinces of Baluchistan, and there is abundance of vegetables. Madder, cotton, and indigo are also produced; and the latter is considered superior to that of Bengal. Great attention is given to the culture of the date fruit in the province of Mekran. The domestic animals of Baluchistan are horses, mules, asses, camels, buffaloes, black-cattle, sheep, goats, dogs, and cats, besides fowls and pigeons; but there are neither geese, turkeys, nor ducks. The wild animals are tigers, leopards, hyenas, wolves, jackals, tiger-cats, wild dogs, foxes, hares, mangooses, mountain goats, antelopes, elks, red and moose deer, wild asses, &c. Of birds they have almost every species to be met with either in Europe or India.

The principal towns in Baluchistan are as follows:—KHELAT is the capital of the whole country; *Mustoong*, of the province of Sarawan; *Kozdar*, of Jalawan; *Beyla*, of Beyla; *Kej*, of Mekran; *Bagh*, of Cutch-Gundava; and Dadur and Gundava are towns in the last-mentioned province.

The capital stands on an elevated site 7000 feet above the sea, on the western side of a well-cultivated plain or valley, about eight miles long and two or three broad, a great part of which is laid out in gardens and other enclosures. The town is built in an oblong form, and on three sides is defended by a mud wall, 18 or 20 feet high, flanked, at intervals of 250 yards, by bastions, which, as well as the wall itself, are pierced with numerous loopholes for matchlock-men. The defence of the fourth side of the city has been formed by cutting away perpendicularly the western face of the hill on which it is partly built. On the summit of this eminence stands the palace, commanding a distinct view of the town and adjacent country. That quarter of the hill on which the Khan's residence is erected has been enclosed by a mud wall, with bastions; the entrance to it is on the south-western side; and here, as well as at the city gates, which are three in number, there is constantly a guard of matchlock-men. Both town and citadel are, however, completely commanded by the surrounding hills, and are incapable of offering any resistance against artillery. Within the walls there are upwards of 2500 houses, and the number of these in the suburbs probably exceeds one-half of that amount. The houses are mostly built of half-burnt brick or wooden frames, and plastered over with mud or mortar. In general, the streets are broader than those of native towns, and most of them have a raised pathway on each side for foot-passengers, and have also an uncovered kennel in the centre, which is a nuisance, from the quantity of filth thrown into it, and the stagnant rain-water that lodges there. The upper stories of the houses frequently project across the street, and thereby render the part beneath them gloomy and damp. This seems a very rude attempt to imitate the bazaars of Persia and Cabul. The bazaar of Khelat is extensive, well furnished with every kind of goods; all the necessaries of life may be purchased there at a moderate price. The town is supplied with delicious water from a spring in the face of a hill on the opposite side of a plain, whence it meanders nearly through its centre, having the town and suburbs on one side, and on the other the gardens. It may be remarked of this spring, that the waters, at their immediate issue from the smaller channels, possess a considerable degree of tepidity until after sunrise, when they suddenly become exceedingly cold, and remain so during the day.

We have no data from which we can form an accurate computation of the population of Baluchistan, but it may be estimated at about 400,000. The two great races of Baluch and Brahoe, each subdivided into an infinite number of tribes, are clearly distinguished from each other by their language and appearance. The Baluch, or Baluchekee, language partakes considerably of the idiom of the modern Persian, although greatly disguised under a singularly corrupt pronunciation. The Brahoekee, on the other hand, has nothing analogous to Persian, but appears to contain a

great number of ancient Hinduwee words; and, as it strikes the ear, bears a strong resemblance to the dialect spoken in the Panjaub. The Baluches in general have tall figures, long visages, and raised features; the Brahoes, on the contrary, have short, thick bones, with round faces and flat lineaments.

The Baluches are a handsome, active race of men, not possessing great physical strength, but inured to changes of climate and season, and capable of enduring every species of fatigue. In their habits they are pastoral and much addicted to predatory warfare, in the course of which they do not hesitate to commit every kind of outrage and cruelty. Notwithstanding their predatory habits, however, they are considered to be a hospitable people. After the fashion of other barbarous tribes in that part of the world, they will protect and kindly entertain a stranger while their guest, but feel no scruple in robbing and murdering him as soon as he has left their precincts. They are indolent, and unless excited by amusement or war, or compelled to action by some urgent motive, spend their time in idleness, rude dissipation, and the enjoyment of such coarse luxuries as they can procure in lounging, gambling, smoking tobacco or hemp, and chewing opium. The tenets of their religion,—and still more, perhaps, their poverty,—preserve them from the abuse of fermented liquors. Their principal articles of food are milk in all its forms, the flesh of domestic animals, not excepting that of the camel, and game, including wild asses, the flesh of which is considered a delicacy. Their appetites are voracious; they consume incredible quantities of flesh when it can be obtained, and prefer it in a half-cooked state. They also use grain in the form of bread, and prepared variously otherwise; but they enjoy most such articles of food or condiment as possess a strong and stimulating flavour, as capsicum, onions, and garlic. Their indolence prompts them to keep as many slaves as they can obtain and support. Polygamy is universal. Some of the lower orders have as many as eight women, either as wives or mistresses, and the number is increased in proportion to the rank and means of the man. Wives are obtained by purchase, payment being made in cattle or other articles of pastoral wealth. The ceremony of marriage is performed by the moollah or priest; and on this occasion, as well as on some others affecting females, practices similar to those of the Levitical law are observed. For instance, in this country, as also among the Afghans, a man is expected to marry the widow of a deceased brother. When a death takes place, the body is watched for three successive nights by assembled friends and neighbours, who spend their time in feasting, so that the ceremony seems intended rather to furnish enjoyment to the living than to render honour to the dead.

The common dress of the Brahoes is a coarse white or blue calico shirt, buttoned round the neck, and reaching below the knee; their trousers are made of the same cloth, or of a kind of striped stuff called soosee, and puckered round the ankles. On their heads they wear a small silk or cotton quilted cap, fitted to the shape of the skull, and a *kummurbund* or sash, of the same colour, round their waists. The Baluches wear a similar dress, but a turban on the head and wide trousers unconfined at the ankle. In winter the chiefs and their relatives appear in a tunic of chintz, lined and stuffed with cotton; and the poorer classes, when out of doors, wrap themselves up in a surtout made of cloth, manufactured from a mixture of goats' hair and sheep's wool. The women's dress is very similar to that of the men; their trousers are preposterously wide, and made of silk, or a mixture of silk and cotton.

The fluctuation of power renders it difficult to define precisely the nature of the government of Khelat. During the reign of Nusseer Khan the whole kingdom might be said to have been governed by a complete despotism; yet that ruler so tempered the supreme authority by the privileges granted to the feudal chiefs within their own tribes, that, to a casual observer, it bore the appearance of a military confederation. The tribes all exercise the right of selecting their own *sirdar*, or head; and the khan has the power of confirming or disapproving of their nomination; but this power is never exercised, and appears to be merely nominal. The khan of Khelat declares war and makes treaties connected with the whole of Baluchistan, and can order the sirdar of each tribe to attend in person with his quota of troops. Agreeably to a code of regulations framed by one of the earliest princes of the Kumburanee dynasty, the entire administration of justice was vested in the person at the head of the government. The sirdar, however, has the power of adjusting petty quarrels, thefts, and disputed points of every description, among the inhabitants of a kheil or society; but, in all cases of importance, an appeal lies in the last instance to the khan at Khelat.

The amount of revenue enjoyed by the khan of Khelat is inconsiderable, as the ruling races, Baluch and Brahoe, pay no direct taxes, and their poverty and simple habits prevent them from contributing much indirectly. His income is therefore derived from his resources as a proprietor of lands or towns; from a proportion of the produce paid in kind by the Afghan, Dehwar, and Jet cultivators; from dues on direct and transit trade; and from arbitrary exactions, a never-failing mode with Eastern potentates of recruiting an exhausted treasury. Pottinger estimated the amount at 350,000 rupees, Masson, who had ample means of acquiring information through colloquial channels, at 300,000. At the present date (1875) it is 300,000 rupees or £30,000 at the utmost. With such a revenue it is obvious that no standing army can be maintained; and Masson, certainly very competent to the task of acquiring information on this subject, states that Mehrab Khan, "nearly destitute of troops in his own pay, was compelled, on the slightest cause for alarm, to appeal to the tribes, who attended or otherwise as suited their whims or convenience." Pottinger computed the number of available fighting men at 60,000. Mehrab Khan could on no occasion assemble more than 12,000; and in his final struggle for property, power, and life, the number of his troops did not amount to 3000. At the present time (1875) about 40,000 would probably be available if all attended the summons, but the utmost number the khan could collect would be about 10,000. All depends upon the state of the treasury, the cause of the war, and the power the khan may be able to exert over his chiefs. The Baluch soldier is heavily encumbered with arms, carrying a matchlock, a sword, a dagger, and a shield. Pottinger considered them good marksmen, and states that in action they trust principally to their skill in this respect, avoiding close combat; but their readiness in general to close with the British troops shows that he is in this instance mistaken. There were no Brahoes opposed to our forces at the battle of Meanee, nor were there any Baluches from Baluchistan. The levies of the Ameer of Sindh were principally composed of Sindee and Baluch tribes, who had long been settled in Sindh. The greater part serve on foot; but a number, not inconsiderable, have horses. Camels are only used by tribes on the western borders of Baluchistan in their predatory excursions.

BALUE, Jean, a French cardinal, who raised himself from a very mean station to dignity and honours. He was born of very humble parentage at Angle in Poitou, in 1421, and was first patronised by the bishop of Poitiers He eventually became almoner to Louis XI., and managed to secure a considerable share in the government; but

being detected in treasonable correspondence with the duke of Bourgogne, he was confined by Louis in an iron cage 8 feet square. On his release, however, eleven years afterwards, he was loaded with honours by Sixtus IV., was sent as legate to France, and received the bishopric of Albano. He died at Ancona in 1491.

BALUZE, ÉTIENNE, a celebrated French scholar, was born at Tulle on the 24th of December 1630, and died in July 1718. After completing his education at the university of Toulouse, he was invited by M. de Marca, afterwards archbishop of Paris, to undertake the superintendence of his library. De Marca died in 1662, and Baluze, after acting as librarian to Le Tellier and the archbishop of Auch, obtained in 1667 a similar situation with the famous Colbert, which he retained till 1700, some years after the death of that minister. His reputation and his mastery of French law and antiquities obtained for him in 1670 the professorship of canon law in the royal college, a chair founded expressly for him. On the fall of the Cardinal de Bouillon in 1710, Baluze, who had attached himself to his party, was removed by a *lettre de cachet* from Paris, and transferred from Rouen to Blois, Tours, and Orleans in succession. He obtained his recall in 1713, though he never recovered his professorship. Of Baluze's numerous works the best known is the *Capitularia Regum Francorum*, which is of considerable historical value. The *Miscellanea*, in 7 vols., contain several curious extracts from manuscripts found by him in the libraries at Paris.

BALZAC, HONORÉ DE, perhaps the greatest name in the post-Revolutionary literature of France, was born at Tours in 1799, and died in 1858. His date thus corresponds with the whole period of the rise, the acme, and the decline of the Romantic school, to which he can scarcely, however, be said to have belonged. It is true that he was inspired by many of the influences that animated Victor Hugo and his followers. Like them he was much occupied by the study of the fantastic element in mediæval art, so strongly opposed to the calm and limit of classical literature, like them he reproduced the remoter phases of life and passion, and thought that few subjects were so base or obscure as to be unworthy of artistic treatment. But there is something in the powerful personality of Balzac indicated by the colossal body, by the strong and sensual face, somewhat resembling the profile of the Emperor Nero, which preserved him from the mannerism of any school. He was never successful in reproducing the existence of the past, he was essentially the man of his own day, and *La Comédie Humaine* is as much the picture of the 19th, as the *Divina Commedia* is of the 13th century. The passions that move his characters are the intense desire of boundless wealth, of luxury, of social distinction; and though here and there his financiers, his journalists, his political intriguers, his sordid peasantry, are relieved by the introduction of some pure figure, like that of Eugénie Grandet, of David, or of Eve, there are only too many elaborate studies of creatures sunk below the surface of humanity, the embodiments of infinite meanness and nameless sin. He was merely "the secretary of society," he said, and "drew up the inventory of vices and virtues." His ambition was, "by infinite patience and courage, to compose for the France of the 19th century that history of morals which the old civilizations of Rome, Athens, Memphis, and India, have left untold." The consequence of this ambition is, that Balzac's voluminous romances have too often the air of a minute and tedious chronicle, and that the contemporary reader is wearied with a mass of details about domestic architecture, about the stock exchange, and about law, which will prove invaluable to posterity.

Balzac's private history, which may be traced through many passages of his novels, was a strange and not a happy one. He was early sent from his home in Tours to the college of Vendôme, where he neglected the studies and sports of childhood to bury himself in mystic books and mystic reveries. He has told the story of his school life in *Louis Lambert*, how he composed a *théorie de la volonté*, a theory which was to complete the works of Mesmer, Lavater, Gall, and Bichat. This promising treatise was burned by one of the masters of the school; and Balzac, falling into bad health, returned home. The next stage in his education was a course of study at the Sorbonne, and of lectures on law. In the offices of *avoués* and notaries he picked up his knowledge of the by-ways of chicanery,—knowledge which he uses only too freely in his romances. Nature did not mean Balzac for an advocate; he was constant in the belief in his own genius, a belief which for many years he had all to himself, and his family left him to work and starve, on the scantiest pittance, in a garret of the Rue Lesdiguières. There followed ten years of hard toil, poverty, experiments in this and that way of getting a living. These struggles are described in *Facino Cane*, in the *Peau de Chagrin*, and in a series of letters to the author's sister, Madame de Surville. Balzac found "three sous for bread, two for milk, and three for firing" suffice to keep him alive, while he devoured books in the library of the Arsenal, copied out his notes at night, and then wandered for hours among the scenes of nocturnal Paris. "Your brother," he writes to Madame de Surville, "is already nourished like a great man, he is dying of hunger." He tried to make money by scribbling many volumes of novels without promise, and borrowed funds to speculate in the business of printing. Ideas which have since made other men's fortunes failed in Balzac's hands, and he laid the foundations of those famous debts which in later life were his torment and his occupation. At length appreciation came, and with appreciation what ought to have been wealth. Balzac was unfortunately as prodigal of money as of labour; he would shut himself up for months, and see no one but his printer; and then for months he would disappear and dissipate his gains in some mysterious hiding-place of his own, or in hurried travelling to Venice, Vienna, or St Petersburg. As a child he had been a man in thought and learning; as a man he was a child in caprice and extravagance. His imagination, the intense power with which he constructed new combinations of the literal facts which he observed, was like the demon which tormented the magician with incessant demands for more tasks to do. When he was not working at *La Comédie Humaine*, his fancy was still busy with its characters; he existed in an ideal world, where some accident was always to put him in possession of riches beyond the dreams of avarice. Meantime he squandered all the money that could be rescued from his creditors on sumptuous apparel, jewels, porcelain, pictures. His excesses of labour, his sleepless nights, his abuse of coffee undermined his seemingly indestructible health. At length a mysterious passion for a Russian lady was crowned by marriage; the famous debts were paid, the visionary house was built and furnished, and then, "when the house was ready, death entered." Balzac died at the culmination of his fame, and at the beginning, as it seemed, of the period of rest to which he had always looked forward.

It is impossible to enter on a detailed criticism of Balzac's novels. In them he scales every height and sounds every depth of human character,—from the purity of the mysterious Seraphitus Seraphita, cold and strange, like the peaks of her northern Alps, to the loathsome sins of the Marnefs, whose deeds should find no calendar but that of Hell. In the great divisions of his *Comédie*, the scenes of private and of public life of the provinces and of the city,

in the philosophic studies, and in the *Contes Drolatiques*, Balzac has built up a work of art which answers to a mediæval cathedral. There are subterranean places, haunted by the Vautrins and "Filles aux yeux d'or;" there are the seats of the money-changers, where the Nucingens sit at the receipt of custom; there is the broad platform of everyday life, where the journalists intrigue, where love is sold for hire, where splendours and miseries abound, where the peasants cheat their lords, where women betray their husbands; there are the shrines where pious ladies pass saintly days; there are the dizzy heights of thought and rapture, whence falls a ray from the supernatural light of Swedenborg; there are the lustful and hideous grotesques of the *Contes Drolatiques*. Through all swells, like the organ tone, the ground-note and mingled murmur of Parisian life. The qualities of Balzac are his extraordinary range of knowledge, observation, sympathy, his steadfast determination to draw every line and shadow of his subject, his keen analysis of character and conduct. His defects are an over-insistence on detail, which hampers and bewilders rather than aids the imagination of his readers; his tortured style, "a special language forged out of all the slangs, all the terminologies of science, of the studio, the laboratory, the *coulisses*;" his fondness for dwelling on the morbid pathology of human nature. With all these defects, and with the difficulty of judging any one of his tales separately, because each is only a fragment in the development of the immense *Comédie Humaine*, Balzac holds a more distinct and supreme place in French fiction than perhaps any English author does in the same field of art. (A. L.)

BALZAC, JEAN LOUIS GUEZ DE, a celebrated French writer, was born at Angoulême in 1594. His father was possessed of considerable property, and he himself was early befriended by the Cardinal de la Valette, who took him in his train to Rome. His letters written from that place to his acquaintances and to many who held a high position at the French court, were expressed so admirably, and showed such powers of eloquence, as to gain for him the highest renown. On his return from Italy he was at once and everywhere received as a master in the art of composition. The most extravagant compliments were showered upon him, and his head appears to have been turned a little by his success. In 1624 a collection of his *Letters* was published, and was received with great favour by the public. Soon afterwards a direct charge of plagiarism was made against Balzac in a pseudonymous tract, *On the conformity of M. de Balzac's Eloquence with that of the Greatest Personages of Past and Present Time*. A terribly fierce paper war was excited by this pamphlet; and Balzac, in disgust, retired to his own estate, where he continued his labour of composition. In 1634 he expressed a desire to enter the Academy, and was at once elected with universal acclamation. He died at Paris in 1654. His fame rests entirely upon the *Letters*, which, though empty, bombastic, and affected in matter, are written with great skill, and show a real mastery over the language. They introduced a new style; and Balzac has thus the credit of being the first reformer of French prose, as his contemporary Malherbe was the first reformer of French poetry.

BAMBA, a province of Congo, on the western coast of Africa, lying to the S. of the River Ambriz. This district is fertile, abounds in gold, silver, copper, salt, &c., and is said to be thickly populated. Its chief town, which bears the same name, was formerly of considerable importance, the climate being remarkably healthy for that region of Africa.

BAMBARRA, a country of inner Africa, on the Joliba or Upper Niger. The principal towns are Segu, Sansading, Jamima, Mursha, Jabbi, Sai, Kullikoro, Maraca-Duba, and Damba, in many of which the Mahometans have mosques For further particulars see AFRICA, vol. i. p. 271.

BAMBARRA, a town of western Africa on a backwater of the Niger, of considerable commercial importance, and situated in a fertile plain, 115 miles S.S.W. of Timbuctoo. (See Barth's *Travels in Central Africa*, vol. iv. p. 354.)

BAMBERG, a town of Bavaria, in the circle of Upper Franconia, on the River Regnitz, 3 miles above its junction with the Maine, and 33 miles N. of Nuremberg, with which it is connected by railway. It is partially surrounded by walls and ditches, and is divided by the river and Ludwig's canal into three districts, which are connected by handsome bridges. The town is well built, and the streets are well paved and lighted. The cathedral, a noble structure in the Byzantine style of architecture, is surpassed by few of the kind in Germany. It was founded in 1004 by the Emperor Henry II., and finished in 1012, but was afterwards partially burnt, and rebuilt in 1110. It contains the tombs of the founder and his empress Cunigunde, Conrad III., Pope Clement II., &c., and numerous monuments and paintings by eminent masters. Among the other public buildings are St Martin's church, the palace (formerly the residence of the prince-bishops), town-house, and theatre. The Benedictine convent of St Michael was turned, in 1803, into a charitable institution for poor citizens known as Ludwig's hospital. Bamberg has numerous literary and charitable institutions, as the lyceum, gymnasium, polytechnic, normal, and medical schools, a library, museum, picture-gallery, hospital, and workhouse. The trade is considerable; cloths, sealing-wax, leather, tobacco, musical instruments, carriages, &c., are manufactured, and there are numerous breweries. The whole of the neighbouring district is like a vast garden, and furnishes large supplies of liquorice, carrots, aniseed, coriander, and other seeds. Bamberg was formerly the capital of an independent bishopric, which was secularized in 1801, and assigned to Bavaria in 1803. Population, 25,738.

BAMBOCCIO. See LAER, PETER VAN.

BAMBOO, a genus (*Bambusa*) of arborescent grasses very generally distributed throughout the tropical lands of the globe, but found and cultivated especially in India, China, and the East Indian Archipelago. There is a large number of species enumerated; but, as is the case with most plants under cultivation, much difficulty is found in distinguishing species from varieties produced by artificial selection. *Bambusa arundinacea* is the species most commonly referred to. It is a tree-like plant, rising to a height of 40, 60, or even 80 feet, with a hollow stem, shining as if varnished. The stem is extremely slender, not exceeding the thickness of 5 inches in some which are 50 feet high, and in others reaching 15 or 18 inches in diameter. The whole is divided into joints or septa called knots or internodes, the intervals between which in the case of some of the larger stems is several feet. These joints or divisions are formed by the crossing of the vascular bundles of fibres. They produce alternate lateral buds, which form small alternate branchlets springing from the base to the top, and, together with the narrow-pointed leaves issuing from them, give the plant an elegant feathered appearance as it waves in the wind. The rapidity of its growth is surprising. It attains its full height in a few months, and Mr Fortune records the observation of a growth of from 2 to 2½ feet in a single day. In Malabar it is said to bear fruit when fifteen years old, and then to die.

The bamboo is cultivated with great care in regular plantations by the Chinese. The plant is propagated by shoots or suckers deposited in pits 18 inches or 2 feet deep at the close of autumn or the beginning of winter. Various expedients are followed to obtain good bamboos; one of the most usual being to take a vigorous root and transplant

it, leaving only four or five inches above the joint next the ground. The cavity is then filled with a mixture of horse-litter and sulphur. According to the vigour of the root, the shoots will be more or less numerous; they are destroyed at an early stage during three successive years; and those springing in the fourth resemble the parent tree. The uses to which all the parts and products of the bamboo are applied in Oriental countries are almost endless. The soft and succulent shoots, when just beginning to spring, are cut over and served up at table like asparagus. Like that vegetable, also, they are earthed over to keep them longer fit for consumption; and they afford a continuous supply during the whole year, though it is more abundant in autumn. They are also salted and eaten with rice, prepared in the form of pickles, or candied and preserved in sugar. As the plant grows older, a species of fluid is secreted in the hollow joints, in which a concrete substance, highly valued in the East for its medicinal qualities, called *tabaxir* or *tabascheer*, is gradually developed. This substance, which has been found to be a purely siliceous concretion, is possessed of peculiar optical properties. As a medicinal agent the bamboo is almost or entirely inert, and it has never been received into the European materia medica. A decoction of the leaves of the plant is, however, employed in the East for pectoral affections, and the leaf-buds are said to be diuretic. The grains of the bamboo are available for food, and the Chinese have a proverb that it produces seed more abundantly in years when the rice crop fails, which means, probably, that in times of dearth the natives look more after such a source of food. The Hindus eat it mixed with honey as a delicacy, equal quantities being put into a hollow joint, coated externally with clay, and thus roasted over a fire. It is, however, the stem of the bamboo which is applied to the greatest variety of uses. Joints of sufficient size form water buckets; smaller ones are used as bottles, and among the Dyaks of Borneo they are employed as cooking vessels. Bamboo is extensively used as a timber wood, and houses are frequently made entirely out of the products of the plant; complete sections of the stem form posts or columns; split up, it serves for floors or rafters; and, interwoven in lattice-work, it is employed for the sides of rooms, admitting light and air. The roof is sometimes of bamboo solely, and when split, which is accomplished with the greatest ease, it can be formed into laths or planks. It is employed in shipping of all kinds; some of the strongest plants are selected for masts of boats of moderate size, and the masts of larger vessels are sometimes formed by the union of several bamboos built up and joined together.

The bamboo is employed in the construction of all kinds of agricultural and domestic implements, and in the materials and implements required in fishery. Bows are made of it by the union of two pieces with many bands; and, the septa being bored out and the lengths joined together, it is employed, as we use leaden pipes, in transmitting water to reservoirs or gardens. From the light and slender stalks shafts for arrows are obtained; and in the south-west of Asia there is a certain species of equally slender growth, from which writing-pens or reeds are made. A joint forms a holder for papers or pens, and it was in a joint of bamboo that silk-worm eggs were carried from China to Constantinople during the reign of Justinian. The outer cuticle of Oriental species is so hard that it forms a sharp and durable cutting edge, and it is so siliceous that it can be used as a whetstone. This outer cuticle, cut into thin strips, is one of the most durable and beautiful materials for basket-making, and both in China and Japan it is largely so employed. Strips are also woven into cages, chairs, beds, and other articles of furniture, Oriental wicker-work in bamboo being unequalled for beauty and neatness of workmanship. In China the interior portions of the stem are beaten into a pulp, and used for the manufacture of the finer varieties of paper. Bamboos are imported to a considerable extent into Europe for the use of basket-makers, and for umbrella and walking-sticks. In short, the purposes to which the bamboo is applicable are almost endless, and well justify the opinion that "it is one of the most wonderful and most beautiful productions of the tropics, and one of Nature's most valuable gifts to uncivilized man" (A. R. Wallace, *The Malay Archipelago*).

BAMBOROUGH, a village in Northumberland, on the sea-coast, 14 miles N. of Alnwick. It was a royal borough previous to the Norman Conquest, and returned two members to parliament in the 23d year of Edward I. Its ancient castle stands close to the sea on an almost perpendicular rock, 150 feet in height, and is accessible only on the south-east side. The first erection is ascribed by the Saxon chronicles to King Ida of Northumberland, who is said to have named it *Bebbanburh* after his queen Bebbe (547 A.D.) The principal events in its early history are the siege by Penda in 642, the ravages of the Danes in 993, the unsuccessful defence by De Mowbray against William Rufus, and numerous sieges during the Wars of the Roses. In the reign of Henry VII. it fell into decay. At length, in the 18th century, it became the property of Lord Crewe, bishop of Durham, who, in 1720, vested the castle and manor in trustees for charitable purposes. In virtue of this bequest a patrol is kept on the coast, apartments are provided for shipwrecked seamen, and a store house for salvage-goods, and granaries are maintained in order to supply corn to the poor at a cheap rate in times of scarcity. An infirmary, a dispensary, and a large library bequeathed by Dr. Sharp, are also maintained, while poor children receive gratuitous education at two "national" schools. Population in 1871, 320 in the village, and 3751 in the parish.

BAMBOUK, a country in the interior of Western Africa, situated between the Senegal and its tributary the Faleme, and extending from lat. 12° 30′ to 14° N., and from long. 10° to 12° 30′ W. It is traversed from N.W. to S.E. by the steep and wall-like range of the Tamba-Ura Mountains. The soil in a large part of the country is of remarkable fertility; rice, maize, millet, melons, manioc, grapes, bananas, and other fruits, grow almost without cultivation; the forests are rich in a variety of valuable trees; and extensive stretches are covered with abundant pasturage of the long guinea-grass. As a natural consequence there is great profusion of animal life. The inhabitants, a branch of the Mandingo race, have made but little progress in civilization. The one product of their country which really excites them to labour is gold; and even it is so common and accessible that the rudest methods of collection are deemed sufficient. The most remarkable deposit is at Natakoo, where a considerable hill seems to be wholly composed of auriferous strata. There is also a good mine at Kenieba. In exchange for the gold, cloth, ornaments, and salt—the last a most valuable article—are imported. The usual beast of burden is the ass, the horse being only possessed by the very wealthiest in the country. Sheep and cattle are both pretty numerous. Unfortunately, the climate is very unhealthy, especially in the rainy season, which lasts for about four months, from July or August. The chief towns are Bambouk, Salaba, and Konkuba. The Portuguese early penetrated into Bambouk, and were even for some time masters of the country; but the inhabitants made a general rising and completely drove them out. Remains of their buildings, however, are still to be seen. The French, soon after they had formed their settlement on the Senegal, turned their attention to this land of gold. It was not till 1716, however, that Compagnon, under the auspices of De la Brue, the governor of Senegal, succeeded, by great

address, and not without risk, in visiting various parts of the auriferous region; and his explorations were followed up by David, Levens, and others. Raffenel visited the country in 1844, and Pascal, a naval lieutenant, was there in 1859. A few commercial stations or *comptoirs* have recently been established.

BÁMIÁN, a once renowned city in the territory now subject to the Afghans, in 34° 50′ N. lat., 67° 44′ E. long. Its remains lie in a valley of the Hazara country, on the chief road from Kábul towards Turkestán, and immediately at the northern foot of that prolongation of the Indian Caucasus now called Koh-i Baba (see vol. i. pp. 227, 241). The passes on the Kábul side are not less than 11,000 and 12,000 feet in absolute height, and those immediately to the north but little inferior. The river draining the valley is one of the chief sources of the Surkháb or Aksarai, an important tributary of the Upper Oxus (*ibid.* p. 241). The prominences of the cliffs which line the valley are crowned by the remains of numerous massive towers, whilst their precipitous faces are for 6 or 7 miles pierced by an infinity of ancient cave-dwellings, some of which are still occupied. The actual site of the old city is marked by mounds and remains of walls, and on an isolated rock in the middle of the valley are considerable ruins of what appears to have been the acropolis, now known to the people as Ghúlgúlah. But the most famous remains at Bámián are two colossal standing idols, carved in the cliffs on the north side of the valley. Burnes estimates the height of the greater at 120 feet, the other at half as much. These images, which have been much injured, apparently by cannon-shot, are cut in niches in the rock, and both images and niches have been coated with stucco. There is an inscription, not yet interpreted or copied, over the greater idol, and on each side of its niche are staircases leading to a chamber near the head, which shows traces of elaborate ornamentation in azure and gilding. The surface of the niches also has been painted with figures. In one of the branch valleys is a similar colossus, somewhat inferior in size to the second of those two; and there are indications of other niches and idols. As seen from the rock of Ghúlgúlah, Bámián, with its ruined towers, its colossi, its innumerable grottoes, and with the singular red colour of its barren soil, presents an impressive aspect of desolation and mystery.

That the idols of Bámián, about which so many conjectures have been uttered, were Buddhist figures, is ascertained from the narrative of the Chinese pilgrim, Hwen Thsang, who saw them in their splendour in 630 A.D. His description of the position of the city and images corresponds accurately with modern reports. He assigns to the greater image, which was gilt (the object, probably, of the plaster coating), a height of 140 or 150 feet, and to the second 100. The latter would seem from his account to have been sheathed with copper. Still vaster than these was a recumbent figure, 2 miles east of Bámián, representing Sakya Buddha entering *Nirvána, i.e.,* in act of death. This was "about 1000 feet in length." No traces of this are alluded to by modern travellers, but in all likelihood it was only formed of rubble plastered (as is the case still with such *Nirvána* figures in Indo-China), and of no durability. For a city so notable Bámián has a very obscure history. It does not seem possible to identify it with any city in classical geography: *Alexandria ad Caucasum* it certainly was not. The first known mention of it seems to be that by Hwen Thsang, at a time when apparently it had already passed its meridian, and was the head of one of the small states into which the empire of the White Huns had broken up. At a later period Bámián was for half a century, ending 1214 A.D., the seat of a branch of the Ghori dynasty, ruling over Tokháristán, or the basin of the Upper Oxus. The place was long besieged, and finally annihilated (1222) by Chinghiz Khan, whose wrath was exasperated at the death of a favourite grandson by an arrow from its walls. There appears to be no further record of Bámián as a city; but the character of ruins at Ghúlgúlah agrees with traditions on the spot in indicating that the city must have been rebuilt after the time of the Mongols, and again perished. In 1840, during the British occupation of Kábul, Bámián was the scene of an action in which Colonel Denny with a small force routed Dost Mahommed Khan, accompanied by a number of Uzbeg chiefs. (Burnes, *Journey to Bokhara*; Masson's *Journeys*, and his papers in the *J. As. Soc., Bengal*; Julien, *Pèlerins Bouddhistes*; E. Thomas in *J. R. As. Soc.*, &c.) (H. Y.)

BAMPTON, REV. JOHN, founder of the series of divinity lectures at Oxford known as the *Bampton Lectures*, appears to have been born in 1689 and to have died in 1751. He was a member of Trinity College, Oxford, and for some time canon of Salisbury. His will directs that eight lectures shall be delivered annually on as many Sunday mornings in full term, "between the commencement of the last month in Lent term and the end of the third week in Act term, upon either of the following subjects:—to confirm and establish the Christian faith, and to confute all heretics and schismatics—upon the divine authority of the Holy Scriptures—upon the authority of the writings of the primitive fathers, as to the faith and practice of the primitive Church—upon the divinity of our Lord and Saviour Jesus Christ—upon the divinity of the Holy Ghost—upon the articles of the Christian faith as comprehended in the Apostles' and Nicene Creeds." The lecturer, who must be at least a Master of Arts of Oxford or Cambridge, is chosen yearly by the heads of colleges, and no one can be chosen a second time. The series of lectures began in 1780, and has continued to the present time unbroken, with the exception of the years 1834 and 1835, when no lecturers were appointed, and 1841, when no lectures were delivered. Several of the lecturers have been men of great eminence and ability; Heber, for instance, was selected in 1815, Whately in 1822, Milman in 1827, Horne in 1828, Hampden in 1832, Goulburn in 1850, Mansel in 1858, Liddon in 1866. The institution has done much to preserve, at least in some quarters, a high standard in English theology; and the lectures as a whole form a very valuable body of apologetic literature.

BANANA (*Musa sapientum*), a gigantic herbaceous plant belonging to the natural order *Musaceæ*, orginally a native of the tropical parts of the East, but now cultivated in all tropical and sub-tropical climates. It forms a spurious kind of stem, rising 15 or 20 feet by the sheathing bases of the leaves, the blades of which sometimes measure as much as 10 feet in length by 2 feet across. The stem bears several clusters of fruit, which somewhat resemble cucumbers in size and form; it dies down after maturing the fruit. The weight of the produce of a single cluster is sometimes as much as 80 lb, and it was calculated by Humboldt that the productiveness of the banana as compared with wheat is as 133 to 1, and as against potatoes 44 to 1. The varieties of banana cultivated in the tropics are as numerous as the varieties of apples in temperate regions, and the best authorities now agree that no specific difference exists between it and the plantain. The fruit is extensively used as food; and in many of the Pacific islands it is the staple on which the natives depend. In its immature condition it contains much starch, which on ripening changes into sugar; and as a ripe fruit it has a sweet but somewhat flavourless taste. From the unripe fruit, dried in the sun, a useful and nutritious flour is prepared. The following represents the percentage composition of the pulp of the ripe fruit:— Nitrogenous matter, 4·820; sugar, pectin, &c., 19·657; fatty matter, 0·632; cellulose, 0·200; saline matter, 0·791; water, 73·900. An analysis of the flour by Dr Murray Thomson yielded the following results:—Water, 12·33; starch, 71·60; gum and sugar, 6·82; nitrogenous matter, 2·01; cellulose, 5·99; oil, 0·50; salts, 0·64.

BANAT, a district in the south-east of Hungary, consisting of the three counties of Thorontal, Temeswar, and Krasso, which has strangely acquired this title, though it was never governed by a "ban." It is bounded by the Theiss, the Maros, and the Danube, forming almost a regular parallelogram. The soil is in many parts a remarkably rich alluvial deposit. Under the Turkish yoke it was allowed to lie almost desolate in marsh and heath and forest; but Joseph II. determined to render it, if possible, a populous and prosperous district. He accordingly offered land, at a very low rate, to all who were willing to settle within its borders. Germans, Greeks, Turks, Servians, Italians, and Frenchmen responded to his call, and soon developed the agricultural resources of the region. Canals were formed at great expense of labour; marshes and forests were cleared; and now the Banat is one of the most highly cultivated parts of the Austrian empire. Wheat, barley, oats, rye, rice, maize, flax, hemp, rape, sun-flowers, tobacco, grapes, and, in short, nearly all the productions of Europe, are successfully raised. The climate in summer is very like that of Italy, and in winter is milder than in other parts of Hungary. Nor is it any longer unhealthy, though, in 1777, Born spoke of it with horror as a realm of death, and the account given of it in 1802 by Dr Samuel Clarke was not much better. The scenery is extremely diversified, from the plains of Thorontal to the snowy mountains of Krasso. The mineral wealth is considerable, including copper, tin, lead, zinc, iron, and especially coal. Among its numerous mineral springs the most important are those of Menadia, which were known to the Romans as *Thermæ Herculis*. Not only there but in other parts of the Banat numerous remains of the Roman occupation still exist. The various origin of its inhabitants may still be easily traced,—the separate settlements having kept remarkably distinct, and in many cases preserving their native languages and customs. The chief town is Temeswar, and other places of importance are Lugos, Kikinda, Becskereh, and Werschitz. Population about 1,500,000.

See Griselini, *Versuch einer Gesch. des Temeswar Banats*, Vienna, 1785; Hietzinger, *Versuch einer Statistik der Militargrenze des Oesterreich Kaiserth.*, Vienna, 1781; Bohm, *Geschichte des Temeswar Banats*, Leipsic, 1861; Paget, *Hungary*, 1855.

BANBRIDGE, a town of Ireland, county of Down, on the Bann, 23 miles S.W. of Belfast, standing on the summit of an eminence. To facilitate access, a central carriageway, 200 yards long, has been cut through the main street to a depth of 15 feet, the opposite terraces being connected by a bridge. Banbridge is a neat town, with a handsome church, several chapels, a market house (built in 1831), and a court house. It is the principal seat of the linen trade in the county, and has extensive cloth and thread factories, bleachfields, and chemical works. Population in 1871, 5600.

BANBURY, a market-town, municipal and parliamentary borough, and railway junction, in the county of Oxford, 71 miles from London, and a little to the west of the River Cherwell and the Oxford and Birmingham canal. It is well built, and has two or three foundries, several breweries, and some other manufactures, but is chiefly dependent on the neighbouring villages which send their agricultural produce to its market. It was formerly famous for its cheese, and gives its name to a kind of cake of considerable repute. Its ancient cross, now destroyed, is celebrated in the well-known nursery rhyme. During the 17th century the inhabitants of Banbury seem to have been zealous Puritans, and are frequently satirized by contemporary dramatists (Chambers's *Book of Days*, vol. ii. p. 316). At a somewhat earlier period the grammar school, which is now defunct, was of such repute as to be chosen as the model for the constitution of the school of St Paul's. A school of science was erected in 1861. Banbury returns one member to parliament, and the borough (which is partly in Northamptonshire) had, in 1872, a population of 11,726, of whom 4122 were in the town.

Banbury Arms.

BANCA, BANKA, or BANGKA, an island off the east coast of Sumatra, and separated from it by the Strait of Banca, lies between lat. 1° 30′ and 3° 7′ S., and long. 105° 9′ and 106° 54′ E. It varies from 8 to 20 miles in breadth, and has an area of 5000 English square miles. Its mines of tin, which were discovered in 1710, are remarkably productive, and in 1872 yielded no less than 68,148 piculs, the average yield during the previous ten years being 73,961 piculs. The washing is almost wholly carried on by Chinese, and a large part of the metal finds its way to their country. Iron, copper, lead, silver, and arsenic, are also found in the island. The soil is generally dry and stony, and the greater part of the surface is covered with forests, in which the logwood tree especially abounds. Its mountains, which scarcely exceed 2000 feet in height, are covered with vegetation to their summits. They are of granitic formation, containing felspar, quartz, mica, and tourmaline. Population, 54,339, including 17,070 Chinese, 37,070 natives, 116 Europeans, and 56 Arabs. Muntak, the capital, has upwards of 3000 inhabitants. "The houses, which mostly belong to Chinamen, are neatly built and well painted; the streets are kept in good repair, and the whole place has an air of enterprise and thrift" (*vide* Bickmore's *East Indian Archip.*, 1868). There are several other forts on the island. It belongs to the Dutch, who derive from it upwards of 3,000,000 guilders, or £250,000, of annual income, after the expenses of the administration are paid.

See map of Sumatra.

BANCROFT, RICHARD, Archbishop of Canterbury in the reign of James I., distinguished as an inflexible opponent of Puritanism, was born at Farnworth in Lancashire in 1544. He was educated at Cambridge University, studying first at Christ's College, and afterwards at Jesus College. He took his degree of B.A. in 1567, and that of M.A. in 1570. Ordained about that time, he was named chaplain to Dr Cox, then bishop of Ely, and in 1575 was presented to the rectory of Teversham in Cambridgeshire. The next year he was one of the preachers to the university, and in 1584 was presented to the rectory of St Andrew's, Holborn. His unquestionable abilities, and his zeal as a champion of the church in those unsettled times, secured him rapid promotion, and at length the highest ecclesiastical position in the land. He graduated B.D. in 1580, and D.D. five years later. In 1585 he was appointed treasurer of St Paul's Cathedral, London. On February 9, 1589, he preached at Paul's Cross a sermon on 1 John iv. 1, the substance of which was a passionate attack on the Puritans. He described their speeches and proceedings, caricatured their motives, denounced the exercise of the right of private judgment, and set forth the divine right of bishops in such strong language that one of the queen's councillors held it to amount to a threat against the supremacy of the Crown. Sixteen days after the publication of this ecclesiastical manifesto, Bancroft was made a prebendary of St Paul's. Within a few years he was advanced to the same dignity in the collegiate church of Westminster, and in the cathedral church of Canterbury. He was chaplain successively to Lord Chancellor Hatton and Archbishop Whitgift. In May 1597 he was consecrated bishop of London; and from this time, in consequence of the age and incapacity for business of Archbishop Whitgift, he was virtually invested with the power of primate, and had the sole management of

ecclesiastical affairs. Among the more noteworthy cases which fell under his direction were the proceedings against Martin Mar-Prelate, Cartwright and his friends, and the pious Penry, whose "seditious writings" he caused to be intercepted and given up to the Lord Keeper. In 1600 he was sent on an embassy, with others, to Embden, for the purpose of settling certain matters in dispute between the English and the Danes. This mission, however, failed. Bishop Bancroft was present at the death of Queen Elizabeth. He took a prominent part in the famous conference of the prelates and the Presbyterian divines held at Hampton Court in 1604. By the king's desire he undertook the vindication of the practices of confirmation, absolution, private baptism, and lay excommunication; he urged, but in vain, the re-inforcement of an ancient canon, "that schismatics are not to be heard against bishops;" and in opposition to the Puritans' demand of certain alterations in doctrine and discipline, he besought the king that care might be taken for a *praying clergy;* and that, till men of learning and sufficiency could be found, godly homilies might be read and their number increased. In the capacity of a commissioner for ecclesiastical causes (1603), he advocated severe measures for the suppression of "heresy and schism," treating books against Episcopacy as acts of sedition, and persecuting their authors as enemies of the state. In March 1604, Bancroft, in consequence of the death of the primate, was appointed by royal writ president of Convocation then assembled; and he there presented for adoption a book of canons collected by himself. In the following November he was elected successor to Whitgift in the see of Canterbury. He had now but six years of life before him. He continued to show the same zeal and severity as before, and with so much success that Lord Clarendon, writing in his praise, expressed the opinion that "if Bancroft had lived, he would quickly have extinguished all that fire in England which had been kindled at Geneva." In 1605 he was sworn a member of the Privy Council. The same year he engaged in a contest with the judges, and exhibited articles of complaint against them before the lords of the council; but these complaints were overruled. He enforced discipline and exact conformity within the church with an iron hand; and forty-nine ministers of the church were deprived of their livings for disobedience to his injunctions. In 1608 he was chosen chancellor of the University of Oxford. One of his latest public acts was a proposal laid before the parliament for improving the revenues of the church. In the last few months of his life he took part in the discussion about the consecration of certain Scottish bishops, and it was in pursuance of his advice that they were consecrated by several bishops of the English Church. By this act were laid the foundations of the Scottish Episcopal Church. Archbishop Bancroft was "the chief overseer" of the authorised version of the Bible, published within a year of his death. He died at Lambeth Palace, November 2, 1610. His literary remains are very few and unimportant.

BÁNDÁ, a district of British India, in the Allâhâbâd division, under the Lieutenant-Governor of the North-Western Provinces, lies between 24° 59′ 15″ and 25° 55′ 30″ N. lat., and 80° 2′ 45″ and 81° 38′ E. long. It is bounded on the N. by the district of Fathipur, from which it is separated by the River Jamná; on the N.E. by the districts of Fathipur and Allâhâbâd; on the S.E. by the native state of Riwá; on the S. and S.W. by some of the petty states of Bundelkhand; and on the W. and N.W. by the district of Hamírpur. Area, 3030 square miles, of which 1390 are under cultivation, 848 cultivable but not cultivated, 108 revenue free, and 684 uncultivable waste. The census of 1872 took the area at 2908·68 square miles, and returned the district population at 697,610 souls,—viz., Hindus, 657,107; Mahometans, 40,497; Christians, 6. Average density, 230 persons to the square mile. Of the population in 1872, 2897 were landed proprietors, 42,230 agriculturists, and 63,644 non-agriculturists. In some parts the district rises into irregular uplands and elevated plains, interspersed with detached rocks of granite; in others it sinks into marshy lowlands, which frequently remain under water during the rainy season. The sloping country on the bank of the Jamná is full of ravines. To the S.E. the Vindhya chain of hills takes its origin in a low range not exceeding 500 feet in height, and forming a natural boundary of the district in that direction. The principal river of the district is the Jamná, which flows from north-west to south-east, along the N.E. boundary of the district for 125 miles. Its most important tributaries within the district are the Ken, Bágain, Paisuní, and Ohán, all of which take their rise in the Vindhya hills. The principal towns and market villages in the district are Mau, Májhgáon or Rájápur, Marká, Samgará, Augásí, Chillá, and Barágáon, all situated on the bank of the Jamná.

The black soil of the district yields abundant crops of wheat, barley, maize, millet of various sorts, rice, and pulses. Hemp, oil-seeds, sugar, and indigo are also grown, but by far the most important crop is cotton, for which the district is so celebrated that the produce is distinguished in commerce as "Bándá Cotton." The estimated acreage under the principal crops—Gram (*Cicer arietinum*), 138,662 acres; wheat, 134,247; maize, 126,198; cotton, 69,667; barley, 60,976; rice, 20,987; total, 550,737 acres, or 860·52 square miles. The total cultivated area of the district is returned at 1390 square miles. The manufactures of Bándá consist of coarse cotton-cloth, sackcloth, and stone handles for knives. Iron and building stone form the only mineral products. The revenue of the district amounted in 1870-71 to £167,488, the expenditure being £63,425. Since the acquisition of the country by the British, eight settlements of the land revenue have been made at different periods. The last (1834-35) of these adjusted the demand at £134,904, and the total collections amounted in 1870–71 to £131,275. In 1871 the regular police force of 620 men was maintained at a cost of £8920, while a rural constabulary of 2552 men was maintained at the cost of the landholders and villagers. In 1871-72 there were 214 schools in the district, with an average daily attendance of 4695 pupils; expenditure, £2194, of which Government paid £754. Bándá district has only two towns containing upwards of 5000 inhabitants, viz., Bándá (27,746) and Girwán (6670). Bándá, the headquarters of the district, lies on the right bank of the River Ken, in lat. 25° 28′, long. 80° 23′. Thirty-six miles of the Jalalpur branch of the East Indian Railway lie within the district, and eleven first-class roads afford good means of communication—the most important road, both commercially and for military purposes, being that from Mánikpur to Chillá. The climate of Bándá is cold in the winter months, and terribly hot in summer. Frost is rare, except in the moist land adjoining the rivers; the hot winds frequently cause deaths among the natives from exposure to the mid-day heat. Rainfall in 1870-71, 51·3 inches.

Bándá has formed an arena of contention for the successive races who have struggled for the sovereignty of India. Kalinjar town, then the capital, was unsuccessfully besieged by Mahmud of Ghazní in 1023 A.D.; in 1196 it was taken by Kutab-ud-dín, the general of Muhammad Ghorí; in 1545 by Sher Shah, who, however, fell mortally wounded in the assault. About the year 1735 the Rájá of Kalinjar's territory, including the present district of Bándá, was bequeathed to Bájí Ráo, the Marhattá Peshwá; and from the Marhattás it passed by the treaties of 1802-3 to the Company.

BANDA ISLANDS, a group in the East Indian Archipelago, lying to the S. of Ceram, in lat. 4° 30′ S. and long. 129° 50′ E. They are ten or twelve in number, and have an area of about 7150 square miles. Their volcanic origin is distinctly marked. Banda Lantoir, which derives its name from the *lontar* or Palmyra palm, is the largest of the group. From the sea this island appears lofty,—its sides being steep, and crowned by a sort of table-land which extends nearly from one end to the other. The whole is one continuous forest of nutmeg and *Canari* trees, the latter being planted to screen the former from the wind. The unhealthiness of Lantoir has prevented it from becoming the seat of government, for which in other respects it would naturally be chosen. The village of Selam contains the ruins of the chief Portuguese settlement. A considerable

fort, called Hollandia, commands the harbour. Banda Neira lies S. of Lantoir. It is the seat of the Dutch resident, whose jurisdiction extends not only over the Banda Islands, but also over a part of Ceram and several other small groups. Fort Nassau, which was built in 1609, is the chief defence of the islands; and to the right and left of it extends the village of Neira. Gunong Api is to the north of Neira, and derives its name *Fire Mountain*—from its large cone-shaped volcano, which rises 2320 feet above the level of the sea, and is constantly emitting smoke. The peak was ascended by Professor Reinwardt in 1821, by M. S. Muller in 1828, and in 1865 by Mr Bickmore, who has given an interesting account of the adventure. Eruptions took place in 1586, 1598, 1609, 1615, 1632, 1690, 1696, 1712, 1765, 1775, 1778, 1820, 1824; and earthquakes without eruptions occurred in 1629, 1683, 1710, 1767, 1816, and 1852. On the last occasion the sea swept up in an enormous wave over Fort Nassau. Pulo Way—The Water Island—lies north of Neira. It is about 400 or 500 feet high, consists of coral rock, and is esteemed the healthiest of the group. Pulo Rond or Roon—the Chamber Island—is about four miles further N., and was at one time the seat of an English "factory." Rosyngain, about seven miles S.E. of Lantoir, is likely to become of some importance for its gold-mines. It was formerly a convict station for Amboyna. Pulo Pisang—Banana Island—two miles N.E. of Neira, produces fine fruits. The other islands Craka, Capella, Sonangy, &c., are uninhabited. In the space between Banda Lantoir and the islands of Banda Neira and Gunong Api there is a very good harbour, formed with entrances both from the E. and W., which enable vessels to enter it from either of the monsoons. These channels are well defended with several batteries, particularly the western one, which is very narrow. Between Gunong Api and Banda Neira there is a third channel into this harbour from the N., but it is navigable for small vessels only. The principal articles of commerce in the Banda group are nutmegs and mace. The native population having been cleared off by the Dutch, the plantations were worked by slaves and convicts till the emancipation of 1860. The introduction of Malay and Chinese labourers has since taken place. The plantations or *perken* can neither be sold nor divided. About 700,000 lb or upwards of nutmegs are obtained in a year, with a proportionate quantity of mace. The imports are provisions, cloth, and iron-ware from Batavia, and various native productions from the Aru Islands, Ceram, &c.

The Banda Islands were discovered and annexed by the Portuguese Abreus about 1511; but in the beginning of the 17th century his countrymen were expelled by the Dutch. In 1608 the English built a factory on Pulo Way, which was demolished by the Dutch as soon as the English vessel left. Shortly after, however, Banda Neira and Lantoir were resigned by the natives to the English, and in 1620 Pulo Roon and Pulo Way were added to their dominions; but, in spite of treaties into which they had entered, the Dutch attacked and expelled their British rivals. In 1654 they were compelled by Cromwell to restore Pulo Roon, and to make satisfaction for the massacre of Amboyna; but the English settlers not being adequately supported from home, the island was retaken by the Dutch in 1664. They retained undisturbed possession of their conquests in this quarter of the globe until the year 1796, when the Banda Islands, along with all the other Dutch colonies, were conquered by the British. They were restored by the treaty of Amiens in the year 1800, again captured, and finally restored by the treaty of Paris concluded in 1814. In the Presidency of Banda there are 111,194 inhabitants, of whom 6000 belong to Neira.

See Wallace's *Malay Archipelago*; Bickmore's *Indian Archipelago*; Linden's *Banda en Zijne bewoners*, 1873; *Trans. of Dutch Geog. Soc.*, 1874.

BANDELLO, MATTEO, an Italian novelist, was born at Castelnuovo, near Tortona, about the year 1480. He received a very careful education, and entered the church, though he does not seem to have prosecuted his theological course with great zeal. For many years he resided at Mantua, and superintended the education of the celebrated Lucrezia Gonzaga, in whose honour he composed a long poem. The decisive battle of Pavia, which gave Lombardy into the hands of the emperor, compelled Bandello to fly; his house at Milan was burnt and his property confiscated. He took refuge with Cesar Fregoso, an Italian general in the French service, whom he accompanied into France. In 1550 he was raised to the bishopric of Agen, a town in which he resided for many years before his death in 1562. Bandello wrote a number of poems, but his fame rests entirely upon his extensive collection of *Novelle*, or tales, which have been extremely popular. They belong to that species of literature of which Boccaccio's *Decameron* and the queen of Navarre's *Heptameron* are, perhaps, the best known examples. The common origin of them all is to be found in the old *Fabliaux* of the French Trouveurs, though some well-known tales are evidently Eastern, and others classical. Bandello's novels are esteemed the best of those written in imitation of the *Decameron*, though Italian critics find fault with them for negligence and inelegance of style. They have little value in a purely literary point of view, and many of them are disfigured by the grossest obscenity. Historically, however, they are of no little interest, not only from the insight into the social life of the period which they afford, but from the important influence they exercised on the Elizabethan drama. The stories, on which Shakespeare based several of his plays, were supplied by Bandello, probably through Belleforest or Paynter (see Simrock, *Quellen des Shakespeare*). The same is true of Massinger, Beaumont and Fletcher, and others. The most convenient edition of Bandello is that in 9 vols., 1813.

BANDINELLI, BARTOLOMMEO or BACCIO, a Florentine sculptor, was born in 1487, and died 1559. His father was an eminent goldsmith, distinguished for his exquisite designs in chasing gold and silver ornaments; and in this domestic school Bandinelli obtained the first elements of drawing. Showing a strong inclination for the fine arts, he was early placed under Rustici, a sculptor, and a friend of Leonardo da Vinci, with whom he made rapid progress. The ruling motive in his life seems to have been jealousy of Michel Angelo, one of whose cartoons he is said to have torn up and destroyed. Vasari, who gives a very full history of his life, manifests the greatest dislike for his moral character, but at the same time gives him the highest praise as an artist. He is regarded by some as inferior in sculpture only to his great rival, Michel Angelo; at all events, his productions entitle him to a very high place among Italian sculptors. His best works are the marble colossal group of Hercules and Cacus in the Piazza del Gran Duca; his group of Adam and Eve; his exquisite *bassi-rilievi* in the choir of the cathedral of Florence; his copy of the Laocoon; and the figures of Christ and Nicodemus on his own tomb. (See Vasari, *Lives*, iii. 232–296.)

BANDINI, ANGELO MARIA, an Italian author, was born at Florence on the 25th Sept. 1726. Having been left an orphan in his infancy, he was supported by his uncle, Joseph Bandini, a lawyer of some note. He received his education among the Jesuits, and showed a special inclination for the study of antiquities. His first work was a dissertation, *De Veterum Saltationibus*, published in 1749.

In 1747 he undertook a journey to Vienna, in company with the bishop of Volterra, to whom he acted in the capacity of secretary. He was introduced to the emperor, and took the opportunity of dedicating to that monarch his *Specimen Litteraturæ Florentinæ*, which was then printing at Florence. On his return he took orders, and settled at Rome, passing the whole of his time in the library of the Vatican, and in those of the Cardinals Passionei and Corsini. The famous obelisk of Augustus, at that time disinterred from the ruins of the Campus Martius, was described by Bandini in a learned folio volume *De Obelisco Augusti*. Shortly after he was compelled to leave Rome on account of his health and returned to Florence, where he was appointed librarian to the valuable library bequeathed to the public by the Abbé Marucelli. In 1756 he was preferred by the emperor to a prebend at Florence, and appointed principal librarian to the Laurentian library. During forty-four years he continued to discharge the duties of this situation, and died in 1800, generally esteemed and regretted. On his deathbed he founded a public school, and bequeathed the remainder of his fortune to other charitable purposes. The most important of his numerous works are the *Catalogus Codd. MSS. Græc., Lat., Ital., Bib., Laurent.*, 8 vols., 1767–1778, and the *Vita e Lettere d' Amerigo Vespucci*, 1745.

BANDON, or BANDONBRIDGE, an inland town and parliamentary borough of Ireland, in the county of Cork, and twenty miles by rail from the county town, is situated on both sides of the River Bandon, which is here crossed by a bridge of six arches. It has two churches, a handsome Roman Catholic chapel, Protestant and Methodist places of worship, a convent, two market-houses, a spacious quay on the south side of the river, an infirmary, a hospital, a dispensary, several public libraries and reading-rooms, an endowed school, a court-house, a bridewell, and barracks. Its manufacture of woollen and cotton goods have much declined; but there are distilleries, breweries, tanneries, and flour-mills. Population in 1871, 6131.

BANFF, the county town of Banffshire, is a place of great antiquity; according to tradition, it was at times the residence of Malcolm Canmore. It was visited by David I. and his son Henry; and there is a charter of Malcolm IV., signed at Banff the eleventh year of his reign, which corresponds with 1163. The church was given to the monastery of Arbroath by William the Lion, and a convent of Carmelite or White Friars is mentioned in a charter by Robert I., 1324. The town is said to have lost many of its ancient grants, but these, it is added, were renewed in 1324 by King Robert the Bruce, and in 1372 by Robert II. The natural situation of the town is beautiful, having its south-eastern exposure on a gentle slope, the wide blue sea on its N., the River Deveron on the E., and on the S. the richly-wooded country with the magnificent mansion and grounds of the earl of Fife. The streets are well and regularly built and paved, and are remarkable for their cleanliness. The principal buildings are Banff Castle, a plain modern building, belonging to the earl of Seafield, erected upon the site of an old castle, in which Archbishop Sharp was born; the county court buildings; the town-house, surmounted by a spire 100 feet high; a prison; parish church, Episcopal church and parsonage, Free church, United Presbyterian, Independent, Methodist, and Roman Catholic places of worship; Chalmers' Hospital; a mason lodge, of tasteful architecture; the academy, a modern edifice of Grecian design, capable of containing 600 scholars, to which there is attached an extensive museum. There are large and well-conducted seminaries for young ladies, also several libraries, a club-room, branch banks and a savings-bank, public baths, hotels, custom-house, gas and water works, &c. The *Banffshire Journal*, a weekly newspaper, with an extensive circulation, is published on Tuesdays. At one period Banff carried on a considerable manufactory of stockings and linen yarn. A branch of the Great North of Scotland Railway, which leaves Inveramsay Junction and terminates at Macduff, is the direct communication from Aberdeen, and has a station at Bridge of Banff. Another line of railway, which has its terminus at the harbour of Banff, runs in connection with Portsoy, and joins the Great North of Scotland Railway at Grange, near Keith. The principal exports are grain, cattle, salmon, herrings, haddocks, pork, butter, and potatoes. The river fishing is the property of the earl of Fife, with a sea-line extending a considerable distance on each side of the river mouth. The burgh is under the jurisdiction of a provost, three bailies, and five councillors, who manage all the town's affairs. Mr Alexander Cassie of London, a native of Banff, some thirty years ago, left to the poor of the town about £20,000, the interest of which is divided twice a year among the poor. A few years ago, Mr Alexander Chalmers of Clunie, a general merchant and shipowner in Banff, left about £70,000 to build and endow a hospital for sick and destitute. The building, which is near the harbour, has somewhat the appearance of Donaldson's Hospital at Edinburgh.

The town of Macduff, which is fast rising into importance, has a good harbour, branch banks, &c. It is about a mile to the E. of Banff, with which it has communication by a stone bridge of seven arches across the Deveron. Its trade in shipping, &c., is more extensive than that of Banff, to which burgh it was united by the Reform Act. It was an old burgh of barony, called Doune, but soon after it was acquired by the Duff family its name was changed to Macduff. A harbour was then erected, and in 1783 it was made a burgh by George III. Macduff is locally situated within the parish of Gamrie, and has an independent municipal government. Banff and Macduff unite with Elgin, Cullen, Inverurie, Kintore, and Peterhead, in sending a member to parliament. Population within the parliamentary boundaries in 1871, about 4000; municipality, 3557. The weekly market-day of Banff is Friday, on which day a corn market is held; and there are two annual fairs.

BANFFSHIRE, a maritime county in the N.E. of Scotland, lying between lat. 57° 6′ and 57° 42′ N., and long. 2° 15′ and 3° 40′ N., and bounded on the N. by the Moray Firth, E. and S. by Aberdeenshire, and W. by Morayshire and part of Inverness-shire. It has an area of 686 square miles, or 439,219 statute acres, its extent from N. to S. being 50 miles, and from E. to W. 32 miles,— its average breadth not exceeding 14 miles. It contains 21 parishes, and parts of 10 others. Its royal and parliamentary burghs are Banff, Macduff, and Cullen; and its principal harbours are at Banff, Macduff, Cullen, Portsoy, Buckie, and Portgordon. The parliamentary burghs are contributory to Elgin, and the county returns a member to parliament. The parliamentary constituency in 1874–5 was 1737. Many of the schoolmasters, with those of the counties of Aberdeen and Moray, share in Dick's bequest.

The surface of Banffshire presents a very diversified aspect. The lower district is mostly a fine open country of a rich, deep, and highly-cultivated soil, agreeably diversified with gentle risings and young plantations. The upper district is mountainous and, at a distance, wears a bleak, forbidding appearance. But the scene changes on a nearer approach. Extensive farms are found embosomed in its fertile and well-cultivated glens. Some of the mountains are covered with trees in full luxuriance of growth; some presenting a beautiful intermixture of rock and copse, while others are covered with brown heath. The Spey flows along its western, and the Deveron along its eastern boundary; and both yield a considerable revenue from their salmon fish-

ings. The principal mountains of Banffshire proper are Benrinnes and the Knockhill; but Cairngorm, Ben Macdhui, and Ben Aven, the highest summits in Britain, lie on or close to the boundary. The principal noblemen's and gentlemen's seats are Duff House, Cullen House, Park House, Troup House, Forglen House, Drummuir, Kininvie, Balvenie, Aberlour, and Rothiemay. Several of these are elegant mansions, and most of them are surrounded by extensive and tastefully laid-out plantations. The natural woods are inconsiderable both in extent and value.

The geology of Banffshire is very closely connected with that of the neighbouring counties of Aberdeen and Moray, from which it is divided by no natural boundaries. Gneiss, and to a greater extent mica slate, form the lowest stratified rocks running nearly south-west from the coast between Cullen and Portsoy to the upper valleys of the Fiddach, Deveron, and Aven rivers. Generally they are fine grained slaty rocks, and form low rounded mountains, of no great beauty, but decomposing into soils of considerable fertility. In many places the mica slate alternates or passes into quartzite, which differs from it chiefly in the almost entire absence of mica. Quartzite in a more independent form is seen on the coast between Cullen and Buckie, and forms also the Durn Hill near Portsoy, the Binn of Cullen, the Knockhill, and much of the high ground to the south. Where it prevails the soil is far from fertile, and the white, weather-beaten mountains have a very sterile aspect. Connected with this series also beds of limestone are very common, and have been quarried in many places, as near Boyne Castle, Sandend, and Fordyce in the north, and in the interior near Keith, Mortlach, and Tomintoul.

Clayslate occurs in considerable abundance in Banffshire, in some places perhaps merely a finer variety of mica slate, in others coarser in texture, or so-called greywacke. Large masses are seen near Boharm, and from Dufftown south to Kirkmichael. It also forms the north coast from Knock Head by Banff, Macduff, and Gamrie, to the Troup Head, often rising into bold, lofty cliffs, and extends south to Gartly. In several places it is wrought for roofing slates both in this county and in Aberdeenshire. Though no fossils have yet been found in these strata, there is little doubt that they are more or less metamorphosed representatives of the lower portions of the Palæozoic (Silurian and Cambrian) formations.

Resting on these rocks Devonian or Old Red Sandstone and conglomerate beds are seen in a few places. Thus the Morayshire beds cross the Spey near Fochabers, running along the coast to Buckie, and in the Tynet Burn have yielded many characteristic fossil fishes. Gamrie, at the north-east extremity of the county, is also well known for similar remains occurring in calcareous nodules embedded in a bluish grey marly rock, from which they are washed out by a small stream on its way to the sea. The more important species are *Cheiracanthus Murchisoni*, *Cheirolepis Uragus*, *Coccosteus cuspidatus*, *Diplopterus affinis*, *Glyptolepis elegans*, *Osteolepis arenatus*, and *Pterichthys Milleri*. In the interior, near Tomintoul, another large deposit of red sandstone occurs, probably of the same age, but as yet no organic remains have been found in this locality. Indications of still more recent formations are seen in the chalk flints common in the vicinity of Portsoy, and in the Oolite fossils found in the brick clays at Blackpots. The raised beach with recent shells, more than 200 feet above the sea-level, near the old church of Gamrie, is also interesting. As in other parts of Scotland, the surface of the country is covered with masses of boulder clay and stratified drift beds, the materials often derived from a considerable distance and some of the granite boulders several tons in weight.

The most important igneous rock is granite. This rock, a portion of the great central mass of the Grampians, forms the mountains in the extreme south of the country round the sources of the Aven. Benrinnes also consists of it, and smaller masses are seen in Glenlivet and other localities. The well-known "graphic granite" forms a vein on the coast near Portsoy, and gets its name from the quartz and felspar crystals appearing on the polished surface like rude letters. Syenite, a compound of hornblende and felspar, covers a large district running south from near Portsoy to Rothiemay and Huntly in Aberdeenshire. The serpentine of Portsoy, though long known, and said to have been at one time extensively wrought and even sent to France as an ornamental stone, is now almost neglected. Rocks of a similar character may be traced pretty much in a south-west direction to near the sources of the Deveron, and from that into the upper parts of the Don in Aberdeenshire.

Some interesting minerals have been found in Banffshire. Among them may be mentioned magnetite, chromite, and asbestos at Portsoy; fluorite near Boharm, at Keith, and on the Aven; also cyanite and chiastolite in clayslate at Boharm. Attempts were made many years ago to work a vein of sulphuret of antimony near Keith; and more recently mines of hæmatite were opened near Arndilly on the Spey.

The agriculture of Banffshire is conducted upon the newest and most approved principles. The soil, though varying even in adjacent fields, is in general rich and productive, yielding fair crops of wheat, and excellent crops of barley, oats, &c.; and the grass and green crops are equally abundant. About 163,000 acres are under cultivation, the extent of the farms is in general from 150 to 200 arable acres, independently of moorland and pasture-grounds. The duration of leases is nineteen years; although there are still some individuals who possess on liferent, and a few leases are held for a longer term. The whole of the farms, even the smallest pendicles, are under regular rotations of cropping, generally a five or seven course shift. The fields are well laid out and subdivided, and properly cleaned and manured; for which last purpose large quantities of lime, bone-dust, and guano are annually imported. The ridges are all straight; and the fields, at least many of them, are enclosed with stone dykes or other fences. The swamps and wet grounds have also been drained and cultivated, so as to effect a total revolution in the ancient modes of agriculture within the county. The cattle and stock hold a high character; and there are several herds of pure short-horns and pure polled Aberdeenshire cattle maintained in the county. This district was much indebted to one of the earls of Findlater, who, as early as the year 1754, not only introduced and exemplified, on some of his own farms, the most approved practices then known in England, but held out liberal encouragement to his tenants to follow his example. His descendants, the earls of Seafield, have also done much to improve the family estates, adding to them many thousands of acres of arable land; and it may be said with truth that one of the earls was the greatest planter of trees in Great Britain within the present century. In 1846 this nobleman received the honorary gold medal of the Highland and Agricultural Society of Scotland, for his vast and thriving plantations of useful timber trees, in the counties of Banff, Moray, and Nairn. From the year 1811 to 1845, he had planted 18,938,224 Scotch firs, 11,904,798 larches, 843,450 hardwoods; making the enormous aggregate of 31,686,472 forest trees, planted in 8223 acres of enclosed ground.

This county also owes much to the earls of Fife, by whose generous efforts and taste for improvement a vast amount has been done in planting and reclaiming land, by favourable leases to the tenantry, and allowances for draining, &c.

Latterly, improvement has been promoted by agricultural associations, annual premiums being given for the best specimens of live stock and the best productions of the soil. The Banffshire Agricultural Association has two shows yearly for all sorts of stock and produce and agricultural implements, with premiums for superiority in various breeds of cattle, poultry, &c. The valued rental of the county is now upwards of £224,250 sterling.

The manufactures of Banffshire are very unimportant, the inhabitants being principally engaged in agriculture and the rearing of cattle. The salmon-fishery is actively prosecuted on the rivers, and herring and other fisheries on the coast. Distilling is largely carried on in Glenlivet and other places; and there is a woollen factory at Keith.

Banffshire was the scene of many bloody conflicts between the Scots and their Danish invaders. From 1624 to 1645 it was the theatre of almost incessant struggles, and the Covenanting troubles of that period, combined with the frequent conflicts of the clans, were productive of serious evils. Several remains of antiquity are pointed out in different parts of the country, such as the sculptured stone at Mortlach, and the churches of Cullen and Fordyce. Ruins of castles and traces of encampments are often to be met with, and a great number of cairns and tumuli are also found. Among the distinguished men whom Banffshire has produced, the following may be mentioned:—Archbishop Sharp of St Andrews; George Baird, distinguished for his services as sheriff of the county during the time of the Covenanters; Thomas Ruddiman, the grammarian; Walter Goodall, the defender of Mary Queen of Scots; Dr Alexander Geddes; and James Ferguson, the astronomer. The population of the county in 1861 and in 1871 was as follows:—

	Houses.			Persons.		
	Inhabited.	Uninhab.	Building.	Male.	Female.	Total.
1861	11,091	318	92	28,000	31,215	59,215
1871	11,603	370	80	29,367	32,656	62,023

See Robertson's *Collections for a History of the Shires of Aberdeen and Banff*, Spalding Club; Shaw's *History of the Province of Moray*; Cordiner's *Antiquities of the North of Scotland*; and various statistical accounts of Banffshire.

BANGALORE, the administrative capital and most important town of the chief commissionership of Mysore, also a large military cantonment, situated in 12° 58′ N. lat., and 77° 38′ E. long. In 1872 the total population of the Bangalore municipality amounted to 191,300; municipal income in 1872–73, £19,090; expenditure, £17,496; average rate of taxation, 2s. per head of the population. For the protection of the town, a municipal police, consisting of 22 officers and 124 men, was maintained in 1872–73, at a total cost of £2756. Bangalore commands the province of Mysore from a military point of view. The elevation of the district on which it stands renders it healthy for English troops; and a large European and Native force is quartered at the military cantonment,—the Native force in 1872–73 consisting of six regiments of cavalry, numbering 2095 officers and men, and four regiments of infantry, numbering 2149 officers and men. The principal institution of the town is the Bangalore High School or Central College for the province, attended by between four and five hundred pupils. The average annual charge of educating each pupil in 1872–73 was £3, 4s. 6d., of which £2, 3s. 9d. was contributed by the state. Mr Thornton thus writes regarding the history of the town:—

The foundation of the present fort was laid by a descendant of Kempe-Goud, a husbandman of the neighbouring country, who, probably in the 16th century, had left his native village to avoid the tyranny of the *wadeyar* of that place, and settled on a spot a few miles to the north of Bangalore. To the peaceful occupation of a farmer he added that of a warrior, and his first exploit was the conquest of this place, where, and at Savendrug, his family subsequently erected fortresses. Bangalore, with other possessions, was, however, wrested from them by Bijápur. Somewhat later we find it enumerated among the *jágírs* of Sháhjí, father of Sivají, the founder of the Marhattá sway; and at an early period of his career in the service of the Bijápur state, that adventurer seemed to have fixed his residence there. It appears to have passed into the possession of Venkojí, one of the sons of Sháhjí; but he having occupied Tanjor, deemed Bangalore too distant, especially under the circumstances of the times, to be safe. He accordingly, in 1687, entered into a bargain for its sale to Chik Deo, Rájá of Mysore, for three lacs of rupees; but before it could be completed, Kasim Khán, commander of the forces of Aurangzeb, marched upon the place and entered it almost without resistance. This event, however, had no other result than to transfer the stipulated price from one vendor to another; for that general, not coveting the possession, immediately delivered it over to Chik Deo on payment of the three lacs. In 1758, Nanjiráj, the powerful minister of the Rájá, caused Bangalore to be granted, as a *jágír* or fief, to Haidar Alí, afterwards usurper of Mysore, who greatly enlarged and strengthened the fort, which, in 1760, on his expulsion from Seringapatam, served as his refuge from destruction. In 1791 it was stormed by a British army commanded by Lord Cornwallis.

The subsequent history of Bangalore belongs to the general events of Mysore, the province of which it forms the political capital. Bangalore is now one of the handsomest English stations in India, with noble public buildings, spacious and artistically laid out gardens, broad smooth roads, well-supervised bazaars, and a good water supply. The markets display almost every sort of English and Indian fruit or vegetable. Bangalore forms the residence of the chief commissioner of Mysore and the principal officers of his administration, and is well worthy of its place as the political and military capital of the province.

BANGKOK, a city of Siam, which was raised to the rank of capital in 1769. It is situated on both sides of the River Menam, about 20 miles from the sea, in lat. 13° 38′ N. and long. 100° 34′ E. The river is navigable to the city for vessels of 350 tons, but there is a bar at its mouth, which at the lowest ebbs has only six feet of water, and at no time has more than fourteen. The general appearance of Bangkok is very striking, alike from its extent, the strange architecture of its more important buildings, and the luxuriant greenness of the trees with which it is profusely interspersed. The streets are in many cases traversed by canals, and the houses raised on piles, while a large part of the population dwell in floating houses moored along the river sides in tiers three or four deep. The nucleus of the city on the eastern bank is surrounded by a wall 30 feet high, and 10 or 12 feet thick, relieved by numerous towers and bastions; but the rest of the city stretches irregularly for full seven miles along each side of the river, and in some places attains nearly as great a breadth,—the Menam itself being about a quarter of a mile across. All the ordinary buildings are composed of wood or bamboo work; but the temples and palaces are of more solid construction, and are gorgeously ornamented. The spires, and in some cases the whole edifices, are covered with gilding, or many-coloured mosaic of the most grotesque description, while the roofs are adorned with fantastic ridges and gables. In all there are upwards of a hundred temples in the city and suburbs. The palace of the "First King" is enclosed by high white walls, which are about a mile in circumference. It consists of a large number of different buildings for various purposes—temples, public offices, seraglios, the stalls for the sacred elephant, and accommodation for thousands of soldiers, cavalry, artillery, and war elephants, an arsenal, a theatre, &c. The hall of audience, in which the throne of the king stands, is situated in the middle of the principal court. The temples are of great richness, floored with mats of silver, and stored with monuments and relics. In one of them is a famous jasper statue of Buddha. The population of the city is of various nationalities,—Burmese, Peguans, Cambodians, Cochin-Chinese, Malays, Indo-Portuguese, and others, besides the

two predominant classes, the Chinese and Siamese. There is great commercial activity, the principal articles of trade being sugar, pepper, and rice. The supplies of the last article can be brought from a long way inland by means of the river and various canals, such as the *Petrio*, which joins the Bang-Pa-Kong at Kanat. Cardamoms, timber, and tin are also largely exported. European manufactures are extensively imported, the natives being very ready to adopt new methods and machinery; and steam-mills for various purposes are being set up. The river is kept clear by a steam-dredger, and iron bridges of European construction are built across the canals. Gas is used in the palaces of the kings and the houses of many of the nobility. A considerable number of European firms carry on business in the city, and the English Government maintains a consul. Christian missions, both Protestant and Roman Catholic, are maintained, the latter church having established a bishopric. The population is said to amount to 400,000.

The reader will find much curious information on Bangkok in Crawford's *Embassy to Siam*, 2 vols. 1830 (plan at p. 214 of vol. ii.); Pallegoix's *Description du royaume Thai, ou Siam*, 1854; and Bowring's *Siam*, 1857. See also *Jahresbericht des Vereins für Erdk. zu Dresden*, viii. and ix.

BANGOR, a parliamentary borough and market-town of Carnarvonshire, North Wales, nine miles N.E. of Carnarvon, to which it is a contributory borough. It consists mainly of one narrow crooked street of nearly a mile in length, stretching N.E. and S.W. through a romantic valley between two ridges of rock. It stands near the northern entrance of the Menai Strait, and the beauty of its scenery attracts thousands of visitors every year. The principal buildings are the cathedral, episcopal palace, deanery-house, Roman Catholic chapel, several dissenting meeting-houses, free schools, union poorhouse, infirmary, market-house (1862), assembly rooms, temperance hall, three banks, and railway station. The cathedral is an embattled cruciform structure, with a low massive tower crowned with pinnacles. It occupies the site of a more ancient edifice, originally founded about 525, but destroyed by the English in 1071. It was afterwards rebuilt, but suffered severely in the wars between the Welsh and Henry III.; and in 1402 it was burned down during the ravages of Owen Glendower. For more than ninety years it remained in ruins. The choir was rebuilt by Bishop Dean in the time of Henry VII., and the tower and nave were added by Bishop Skeffington in 1532. The principal trade of Bangor consists in the export of slates, which are raised in the quarries six miles distant, and conveyed by a railway to Port Penrhyn, at the mouth of the River Cegid, a little to the east of the town. This port is accessible for vessels of from 200 to 300 tons at all states of the tide, and has a quay upwards of 300 yards in length. Population of burgh in 1871, 9859.

BANGOR, a seaport and market-town of Ireland, county Down, on the south side of Belfast Lough, 12 miles E.N.E. of Belfast. It carries on a considerable trade in cotton and linen and embroidered muslin, and has a bank, a market-house, a parish church, several chapels, and a public library. It is greatly frequented as a bathing-place, especially by the people of Belfast. Remains of an ancient abbey, said to have been destroyed by the Danes in 820, are still to be seen. Population in 1871, 2560.

BANGOR, a seaport town in the state of Maine, North America, capital of the county of Penobscot, on the river of that name, at its junction with the Kenduskeag, 60 miles from the sea. Lat. 44° 47′ 50″ N., long. 68° 47′ W. It was incorporated as a town in 1791, and raised to the rank of a city in 1834. The harbour is spacious, and affords anchorage for the largest vessels at high tide. The chief article of trade is timber, which employs about 2000 ships annually; and there are saw-mills, planing-mills, ship-yards, foundries, and manufactories of furniture. There are numerous good schools arranged on a graduated scale, and churches of about ten different denominations. A theological seminary belonging to the Congregationalists was founded in 1816. A library, instituted in 1843, has upwards of 11,000 volumes. Population in 1870, 18,289.

BANIALUKA, a town and fortress of Turkey, in the eyalet of Bosnia, situated on the Verbas or Verbitza, a navigable tributary of the Save. Its warm baths, for which it is still known, would seem, from the antiquities discovered on the spot, to have been frequented by the Romans. There are upwards of forty mosques in the town, and one of them is regarded as the finest in Turkey. An active trade is carried on, and gunpowder and cloth are manufactured, while in the neighbourhood silver-mining is also prosecuted with success. Banialuka was for a long time the seat of the Bosnian governors, and has been frequently exposed to the vicissitudes of war. In 1688 it was captured for the Austrians by Louis of Baden. Population, 15,000.

BANIM, JOHN, an Irish novelist of great power and ability, was born at Kilkenny in 1798. He received a good education, and at a very early age gave evidence of remarkable genius. In his thirteenth year he entered Kilkenny College, where many other eminent Irishmen have received their training, and devoted himself specially to drawing and painting, in which he became so proficient that he resolved to adopt the profession of an artist. He accordingly proceeded to Dublin and studied for two years in the schools connected with the Royal Society, where he obtained high prizes. For some time afterwards he taught drawing in his native town, and while doing so had the misfortune to fall violently in love with one of his pupils. His affections were returned, but the parents of the young lady interfered and removed her from Kilkenny. She pined away and died in two months. The occurrence made a deep impression on Banim's mind, and this, together with his exposure to the weather on the night of her funeral, caused a severe illness which completely shattered his health. After a partial recovery he set out for Dublin and settled finally to the work of literature. He published a poem, *The Celts' Paradise*, and had some success as a writer for the stage. During a short visit to Kilkenny he married, and at the same time planned, in conjunction with his brother Michael (born 1796), a series of tales illustrative of Irish life. He then set out for London, the great centre of literary activity, and supported himself by writing for magazines and for the stage. A volume of miscellaneous essays was published anonymously in 1824, called *Revelations of the Dead Alive*. In April 1825 appeared the first series of *Tales of the O'Hara Family*, which achieved immediate and decided success. One of the most powerful of them, *Crohoore of the Bill Hook*, was by Michael Banim. In 1826 a second series was published, containing what is decidedly one of the best Irish novels in our literature, *The Nowlans*. John's health had almost entirely given way, and the next effort of the "O'Hara family" was almost entirely the production of his brother Michael. *The Croppy, a Tale of* 1798, is hardly equal to the earlier tales, though it contains some wonderfully vigorous passages. *The Denounced, The Mayor of Windgap, The Ghost Hunter* (by Michael Banim), and *The Smuggler*, followed in quick succession, and were received with considerable favour. Banim, meanwhile, had completely broken down in health, and had become much straitened in circumstances. During his absence in France a movement to relieve his wants was set on foot by the English press, headed by Sterling in the *Times*. A sufficient sum was obtained to remove him from any danger of actual want, and to this Government afterwards added a pension

of £150. He settled in Windgap Cottage, a short distance from Kilkenny; and there, a complete invalid, he passed the remainder of his life. His last piece of literary work was the novel, entitled *Father Connell.* He died in July 1842, aged 44. Banim's true place in literature is to be estimated from the merits of the *O'Hara Tales;* his later works, though of considerable ability, are not unfrequently prolix, and are marked by too evident an imitation of the *Waverley Novels.* The *Tales*, however, show him at his best; they are masterpieces of faithful delineation. The strong passions, the lights and shadows of Irish peasant character, have rarely been so ably and truly depicted. The prevailing quality is a wonderful vehemence, combined with a gloominess extending at times to natural phenomena as well as to the characters of the tale; the incidents are striking, sometimes even horrible, and it is not without some justice that the authors have been accused of *sensationalism*, of straining after melodramatic effect. The lighter, more joyous side of Irish character, which appears so strongly in Lover, does not receive due prominence from the Banims. (See P. J. Murray, *Life of John Banim*, 1857.)

BANJARMASSIN, a district in the south-east of Borneo, which was incorporated by the Dutch in consequence of the war of 1860, in regard to the succession in the sultanate, which had been under their protection since 1787. It is watered by the river system of the Banjar, and traversed by a chain of mountains that in some places reaches the height of 3000 feet. The district has been divided by the Dutch into the residency of Kween and the sub-residencies of Amuntal and Martapura. The town of Martapura was the seat of the sultan from 1771. The principal productions of the district are gold, diamonds, coal, pepper and other spices, drugs, edible birds' nests, gum, wax, rattans, &c. The inland portion is covered with forest, while the flat and swampy seaboard is largely occupied by rice-fields. The inhabitants, who are for the most part Dayaks, are roughly estimated from 300,000 to 600,000.

BANJARMASSIN, the chief town of the above district, also known as Fort Tatas, is situated about 15 miles from the mouth of the Banjar, in lat. 3° 23′ S., long. 114° 37′ E. The most of the houses are built on piles, as the town is subject to frequent inundations. In 1700 the East Indian Company established a factory here; but the place was found to be unhealthy, and the Company's servants were finally attacked by the natives, whom they repulsed with great difficulty. The settlement was abandoned. The English again seized Banjarmassin in 1811, but restored it in 1817. The trade consists in the export of the products of the surrounding country and the import of cloth, Chinese pottery, all kinds of metal goods, opium, tobacco, and salt. The population is of a very mixed character, and is estimated at upwards of 30,000. Of the commercial community the Chinese form a very important portion. The coal mines, discovered in 1846 at Mount Pengaron, to the E., are largely worked by the Dutch.

BANKING

A BANK, in its simplest form, is an institution where money may be deposited for safe keeping; but banks are usually established to lend as well as to receive money; and the profits of a banker are commonly derived from the excess of the interest he receives from those indebted to him over the interest he allows, so far as he allows any, to those who have deposited money with him. Early denunciations of usury (Exod. xxii. 25) show the antiquity of the practice of lending money at interest; but this must have long preceded the origin of the business of both borrowing and lending money. When this first appeared it was not, at least in modern Europe, a distinct profession, but was undertaken by goldsmiths and dealers in precious metals. In the progress of the separation of employments, which is a characteristic of an advancing society, banking became a business of its own, which has again been subdivided into many branches independently pursued. It was, for example, formerly generally allowed to be part of the business of a banker to borrow money by issuing promissory notes payable to bearer, which passed from hand to hand as money, within the sphere of the operations of the banks, and banks thus borrowing money were called *Banks of Issue;* but it has been contended of late years that the function of issuing notes passing by delivery as money should be reserved for the state, or for some institution controlled and directed by the state; and we shall have hereafter to notice the controversy that has arisen on this point, and the steps that have been taken in consequence of it. An explanation of the different species of banks will also properly be deferred till a later stage, but it will be convenient here to give a general sketch of the nature of the business of an ordinary banker. We have said he receives and lends money; he may receive money either on a deposit or on a current or drawing account. When money is received on deposit it is commonly repayable to the depositor alone, to whom a deposit note or receipt is given; but it may also be paid to any one to whom the depositor gives an order on the bank either endorsed on the deposit note or receipt or accompanying it. If the banker undertakes to pay interest on deposits, the rate varies according to the length of the notice the depositor agrees to give before withdrawing the money, the ability of the banker to deal with it being, of course, dependent upon the time he may rely upon keeping it. When money is received on a current or drawing account, the customer of the banker draws it out, as he requires, by means of orders, to which the specific name cheques is given; and, partly for convenience and partly by way of security against fraud, bankers are in the habit of giving their customers books of forms of cheques consecutively numbered. Cheques are generally payable to the person in whose favour they are drawn (the payee) or bearer, though they are sometimes payable to the payee or order, in which case endorsement by the payee is necessary before the money can be received. By the usage of bankers in the United Kingdom a "crossed" cheque, that is, a cheque across the face of which two parallel lines, with the name of a banker or the words "—— & Co." inserted between them, have been drawn, has been long held payable by the banker on whom it is drawn to the payee alone or to another banker; and this usage received the force of law by statutes of the present reign (19 and 20 Vict. c. 25, and 21 and 22 Vict. c. 79).

Bankers lend money by opening credits in their books, against which their favoured customers may draw to the extent of the credits opened; by discounting bills; by the purchase of securities; or by advancing money on securities, &c., &c. It will have been gathered that they also undertake the business of collecting the money for cheques, for bills, and for other securities as they mature, which they may have received from their customers. The labour of collection is much facilitated in England by the fact that bills of exchange are almost invariably made payable in London, and that every country banker has a correspondent among the London bankers who collects for him and pays for him; and the London bankers again maintain an

establishment called the Clearing-house (see p. 328), where their clerks meet to effect their interchanges.

Banking appears to have reached a high state of development among the ancients. The bankers of Greece (τραπεζῖται) and Rome (*argentarii*, *mensarii*, *nummularii*) exercised nearly the same functions as those of the present day, except that they do not appear to have issued notes. They received money on deposit, to be repaid on demands made by cheques or orders, or at some stipulated period, sometimes paying interest for it, and sometimes not. Their profits arose from their lending the balance at their disposal at higher rates of interest than they allowed the depositors. They were also extensively employed in valuing and exchanging foreign moneys for those of Athens, Corinth, Rome, &c., and in negotiating bills of exchange. In general they were highly esteemed, and great confidence was placed in their integrity. The rate of interest charged by the bankers was sometimes very high, but that was not a consequence, as has been alleged, of their rapacity, but of the defective state of the law, which, as it gave every facility to debtors disposed to evade payment of their debts, obliged the bankers to guarantee themselves by charging a proportionally high rate of interest.[1] Banking reappeared in Italy upon the revival of civilization. The bank of Venice is reputed the first in date in the history of modern Europe; but it did not become a bank, as we understand the term, till long after its foundation. Historians inform us that the republic being hard pressed for money, was obliged, upon three different occasions, in 1156, 1480, and 1510, to levy forced contributions upon the citizens, giving them in return perpetual[2] annuities at certain rates per cent. The annuities due under the forced loan of 1156 were, however, finally extinguished in the 16th century; and the offices for the payment of the annuities due under the other two loans having been consolidated, eventually became the Bank of Venice.[3] This might be effected as follows:—The interest on the loan to Government being paid punctually, every claim registered in the books of the office would be considered as a productive capital; and these claims, or the right of receiving the annuity accruing thereon, must soon have been transferred, by demise or cession, from one person to another. This practice would naturally suggest to holders of stock the simple and easy method of discharging their mutual debts by transfers on the office books, and as soon as they became sensible of the advantages to be derived from this method of accounting, bank-money was invented. It will, however, be seen that the establishment thus described was at first no more than the transfer office of a National Debt, transfers of which were accepted at par in discharge of private debts, and it is indeed said that the funded debt transferred sometimes commanded an agio or premium above the current money of the republic. This establishment was ruined, after passing through many changes, by the invasion of the French in 1797.

The origin of modern banking may be traced to the money-dealers of Florence, who were in high repute as receivers on deposit and lenders of money in the 14th century; and banking was indeed practised at Florence in the 13th if not in the 12th century. Mr Macleod writes (*Banking*, vol. i. 289)—

"The names of the Bardi, Acciajuoli, Peruzzi, Pitti, and Medici were famous throughout Europe. In 1345 the Bardi and the Peruzzi, the two greatest mercantile houses in Italy, failed. Edward III. owed the Bardi 900,000 gold florins, which his war with France prevented him paying; and the king of Sicily owed them 100,000 gold florins. The deposits of citizens and strangers with the Bardi were 550,000 gold florins. The Peruzzi were owed 600,000 gold florins by Edward III., and 100,000 by the king of Sicily, and the deposits they owed their customers were 350,000 gold florins. The fall of these two great pillars of credit involved that of multitudes of other smaller establishments, and, says Villani (*Istor. Fiorent.*, xii. 55), the community of Florence had never been thrown into such ruin and disorder before. And thereupon he breaks out against the folly of his fellow-citizens entrusting their money to the care of others for the love of gain. The city, however, recovered from this terrible disaster, and we find that between 1430 and 1433 seventy-six bankers at Florence lent 4,865,000 gold florins. At one time Florence is said to have had eighty bankers, but not any public bank."

The business of banking was not introduced into England till the 17th century, when it began to be undertaken by goldsmiths in London, who appear to have borrowed it from Holland. It was attacked as innovations commonly are. Mr Gilbart, in his *History and Principles of Banking*, quotes, from a pamphlet published in 1676, entitled *The Mystery of the New-Fashioned Goldsmiths or Bankers Discovered*, a passage that may be reproduced,—

"Much about the same time—the time of the civil commotion—the goldsmiths (or new-fashioned bankers) began to receive the rents of gentlemen's estates remitted to town, and to allow them, and others who put cash into their hands, some interest for it if it remained but a single month in their hands, or even a lesser time. This was a great allurement for people to put money into their hands, which would bear interest till the day they wanted it; and they could also draw it out by one hundred pounds or fifty pounds, &c., at a time as they wanted it, with infinitely less trouble than if they had lent it out on either real or personal security. The consequence was that it quickly brought a great quantity of cash into their hands, so that the chief or greatest of them was now enabled to supply Cromwell with money in advance, on the revenues, as his occasion required, upon great advantages to themselves."

Sir Josiah Child also attacked "that innovated practice of bankers in London" in his *New Discourse of Trade*, though he subsequently became himself a banker; and his house, Messrs Child & Co., of Temple Bar, and the house of Messrs Hoare, in Fleet Street, still survive as the only private banks now in existence in London which were established previous to the Bank of England.

Foundation and Early History of the Bank of England.

The Bank of England, which has long been the principal bank of deposit and circulation in Great Britain, and indeed in Europe, was founded in 1694. Its principal projector, Mr William Paterson, an intelligent Scotch gentleman, was afterwards engaged in the ill-fated Darien enterprise. Government being at the time much distressed for want of money, partly from the defects and abuses in the system of taxation, and partly from the difficulty of borrowing because of the supposed instability of the Revolutionary establishment, the bank grew out of a loan of £1,200,000 for the public service. The subscribers, besides receiving 8 per cent. on the sum advanced as interest, and £4000 a year as the expense of management, in all £100,000 a year, were incorporated into a society denominated the Governor and Company of the Bank of England. The charter is dated the 27th of July 1694. It declares, amongst other things, that they shall "be capable, in law, to purchase, enjoy, and retain to them and their successors, any moneys, lands, rents, tenements, and possessions whatsoever; and to purchase and acquire all sorts of goods and chattels whatsoever, wherein they are not restrained by Act of Parliament; and also to grant, demise, and dispose of the same.

"That the management and government of the corporation be committed to the governor and twenty-four direc-

[2] The annuities of the forced loan of 1480 were to be suspended during periods of war.

[3] Cleirac, *Du Negoce, de la Banque*, &c. (Bordeaux, 1656), pp. 112-117, a scarce and valuable volume.

tors, who shall be elected between the 25th of March and the 25th day of April each year, from among the members of the company duly qualified.

"That no dividend shall at any time be made by the said governor and company, save only out of the interest, profit, or produce arising by or out of the said capital, stock, or fund, or by such dealing as is allowed by Act of Parliament.

"They must be natural-born subjects of England, or naturalized subjects; they shall have in their own name, and for their own use, severally, viz., the governor at least £4000, the deputy-governor £3000, and each director £2000, of the capital stock of the said corporation.

"That thirteen or more of the said governors and directors (of which the governor or deputy-governor must be always one) shall constitute a court of directors, for the management of the affairs of the company, and for the appointment of all agents and servants which may be necessary, paying them such salaries as they may consider reasonable.

"Every elector must have, in his own name and for his own use, £500 or more capital stock, and can only give one vote. He must, if required by any member present, take the oath of stock, or the declaration of stock in case he may be one of the people called Quakers.

"Four general courts shall be held in every year, in the months of September, December, April, and July. A general court may be summoned at any time, upon the requisition of nine proprietors duly qualified as electors. The majority of electors in general courts have the power to make and constitute bye-laws and ordinances for the government of the corporation, provided that such bye-laws and ordinances be not repugnant to the laws of the kingdom, and be confirmed and approved according to the statutes in such case made and provided."

The corporation is prohibited from engaging in any sort of commercial undertaking other than dealing in bills of exchange, and in gold and silver. It is authorised to advance money upon the security of goods or merchandise pledged to it, and to sell by public auction such goods as are not redeemed within a specified time.

It was also enacted, in the same year in which the bank was established, by statute 6 William and Mary, c. 20, that the bank "shall not deal in any goods, wares, or merchandise (except bullion), or purchase any lands or revenues belonging to the Crown, or advance or lend to their majesties, their heirs or successors, any sum or sums of money, by way of loan or anticipation on any part or parts, branch or branches, fund or funds of the revenue, now granted or belonging, or hereafter to be granted, to their majesties, their heirs and successors, other than such fund or funds, part or parts, branch or branches of the said revenue only on which a credit of loan is or shall be granted by Parliament." And in 1697 it was enacted, that the "common capital or principal stock, and also the real fund, of the governor and company, or any profit or produce to be made thereof, or arising thereby, shall be exempted from any rates, taxes, assessments, or impositions whatsoever during the continuance of the bank; that all the profit, benefit, and advantage from time to time arising out of the management of the said corporation, shall be applied to the uses of all the members of the said association of the governor and company of the Bank of England, rateably and in proportion to each member's part, share, and interest in the common capital and principal stock of the said governor and company hereby established."

In 1696, during the great recoinage, the bank was involved in great difficulties, and was even compelled to suspend payment of its notes, which were at a heavy discount. Owing, however, to the judicious conduct of the directors, and the assistance of the Government, the bank got over the crisis. But it was at the same time judged expedient, in order to place it in a situation the better to withstand any adverse circumstances that might afterwards occur, to increase the capital from £1,200,000 to £2,201,171. In 1708 the directors undertook to pay off and cancel one million and a half of exchequer bills they had circulating two years before, at 4½ per cent., with the interest upon them, amounting in all to £1,775,028, which increased the permanent debt due by the public to the bank, including £400,000 then advanced in consideration of the renewal of the charter, to £3,375,028, for which they were allowed 6 per cent. The bank capital was then also doubled, or increased to £4,402,342. But the year 1708 is chiefly memorable in the history of the bank, for the Act previously alluded to, which declared, that during the continuance of the corporation of the Bank of England "it should not be lawful for any body politic, erected or to be erected, other than the said governor and company of the Bank of England, or of any other person whatsoever, united or to be united in covenants or partnership, exceeding the number of six persons, in that part of Great Britain called England, to borrow, owe, or take up any sum or sums of money on their bills or notes payable on demand, or in any less time than six months from the borrowing thereof." This proviso is said to have been elicited by the Mine Adventurers Company having commenced banking business and begun to issue notes. It will be seen on examination that the proviso did not prohibit the formation of associations for general banking business; it simply forbade the issue of notes by associations of more than six partners; but the issue of notes was regarded as so essential to the business of banking, that it came to be believed that joint-stock banking associations were absolutely prohibited in England, and no such association was founded until after the legislation of 1826 (see p. 322) expressly permitting them to be established. The charter of the Bank of England, when first granted, was to continue for eleven years certain, or till a year's notice after the 1st of August 1705. The charter was further prolonged in 1697. In 1708, the bank, having advanced £400,000 for the public service, without interest, the exclusive privileges of the corporation were prolonged till 1733. And in consequence of various advances made at different times, the exclusive privileges of the bank were continued by successive renewals till the 1st of August 1855, with the proviso that they might be cancelled on a year's notice to that effect being given after the said 1st of August 1855.

We subjoin an account of the successive renewals of the charter, of the conditions under which these renewals were made, and of the variations in the amount and interest of the permanent debt due by Government to the bank, exclusive of the dead weight

Date of Renewal.	Conditions under which Renewals were made and Permanent Debt contracted.	Permanent Debt. £	s.	d.
1694	Charter granted under the Act 5 and 6 Will. III. c. 20, redeemable upon the expiration of twelve months' notice after the 1st August 1705, upon payment by the public to the bank of the demand therein specified. Under this Act the bank advanced to the public £1,200,000 in consideration of their receiving an annuity of £100,000 a year, viz., 8 per cent. interest and £4000 for management.................... ..	1,200,000	0	0

1764	Charter continued by 4 Geo. III. c. 25, till twelve months' notice after the 1st of August 1786, on payment, &c.			
	Under this Act the bank paid into the Exchequer £110,000, free of all charge.			
1781	Charter continued by 21 Geo. III. c. 60, till twelve months' notice after the 1st of August 1812, on payment, &c.			
	Under this Act the bank advanced £30,000,000, for the public service for three years, at 3 p. cent.			
1800	Charter continued by 40 Geo. III. c. 28, till twelve months' notice after the 1st of August 1833, on payment, &c.			
	Under this Act the bank advanced to Government £3,000,000 for six years without interest; but in pursuance of the recommendation of the committee of 1807, the advance was continued, without interest, till six months after the signature of a definitive treaty of peace.			
	In 1816, the bank, under authority of the Act 56 Geo. III. c. 96, advanced at 3 per cent., to be repaid on or before the 1st of August 1833......	3,000,000	0	0
1833	Charter continued by 3 and 4 Will. IV. c. 98, till twelve months' notice after the 1st of August 1855, with a proviso that it may be dissolved on twelve months' notice after the 1st of August 1855, on payment, &c.	14,686,000	0	0
	This Act directs that in future the bank shall deduct £120,000 a year from their charge on account of the management of the public debt; and that a fourth part of the debt due by the public to the bank, or £3,671,000, be paid off....	3,671,000	0	0
	Permanent advance by the bank to the public, bearing interest at 3 per cent., independent of the advances on account of dead weight, or other public securities held by it......	11,015,000	0	0
1844	Charter continued by 7 and 8 Vict. c. 32, till twelve months after the 1st of August 1855, on payment, &c.			
	This Act exempts the notes of the bank from all charge on account of stamp-duty, and directs that in future the bank shall deduct a further sum of £180,000 a year from the charge on account of the management of the public debt. It also allows notes of the value of £14,000,000 to be issued on securities, separates the banking from the issuing department of the establishment, and effects other important changes.			
1861	The Act 24 and 25 Vict. c. 3, provides fresh terms of payment to endure until the 5th April 1886. The amount to be deducted to be £60,000 *plus* the whole allowance out of profits of issue, making in all at that time £188,078, and now (1875) about £200,000.			
	The amount to be issued on securities was raised to £15,000,000 on 21st February 1866.			

The capital of the bank on which dividends are paid has never exactly coincided with, though it has seldom differed very materially from, the permanent advance by the bank to the public. We have already seen that it amounted in 1708 to £4,402,342. Between that year and 1727 it had increased to near £9,000,000. In 1746 it amounted to £10,780,000. From this period it underwent no change till 1782, when it was increased 8 per cent., amounting to £11,642,400. It continued stationary at this sum down to 1816, when it was raised to £14,553,000 by an addition of 25 per cent. from the profits of the bank, under the provisions of the Act 56 Geo. III. c. 96. The Act for the renewal of the charter 3 and 4 Will. IV. c 98, directed that the sum of £3,671,700, being the fourth part of the debt due by the public to the bank, should be paid to the latter, giving the bank the option of deducting it from its capital. But that has not been done; and after sundry changes, the capital of the bank amounts, as formerly, to £14,553,000.

The Bank of England has been frequently affected by panics amongst the holders of her notes. In 1745 the alarm occasioned by the advance of the Highlanders, under the Pretender, as far as Derby, led to a run upon the bank; and in order to gain time to effect measures for averting the run, the directors adopted the device of paying in shillings and sixpences! But they derived a more effectual relief from the retreat of the Highlanders, and from a resolution agreed to at a meeting of the principal merchants and traders of the city, and very numerously signed, declaring the willingness of the subscribers to receive bank-notes in payment of any sum that might be due to them, and pledging themselves to use their utmost endeavours to make all their payments in the same medium.

During the tremendous riots in June 1780, the bank incurred considerable danger. Had the mob attacked the establishment at the commencement of the riots, the consequences might have proved fatal. But they delayed their attack till time had been afforded for providing a force sufficient to insure its safety. Since that period a considerable military force occupies the bank every night as a protection in any emergency that may occur.

Progress of Banking in England down to Restriction Order of 1797.

The business of banking had meanwhile been undertaken in several of the country towns of England. The still existing bank of Messrs Smith & Co. of Nottingham, the parent of the London establishment of Messrs Smith, Payne, and Smiths, claims to have been established in 1688; the Bristol Old Bank (Messrs Baillie, Cave, and Co.) dates from 1750; the Hull Old Bank (Messrs Pease and Co.) from 1754; and many other country banks trace back their history to the latter half of the last century. It is believed that all these bankers issued their own notes payable to bearer as part of their business; and they were not very scrupulous in regard to the magnitude of the sums for which they were given. The Bank of England had not issued any notes for less than £20 previously to 1759; when it commenced the issue of £10 notes; but the country bankers put in circulation notes for such small sums that Parliament enacted, in 1775, that none should be issued for less than £1. In 1777 this minimum limit was further raised to £5, but in spite of this restriction the number and the amount of the issues of the country bankers soon become dangerously multiplied. The termination of the American War was followed by a great industrial and commercial development at home. Agriculture, commerce, and, still more, manufactures, into which Watt and Arkwright's inventions had been lately introduced, immediately began to advance with a rapidity unknown at any former period. In consequence, that confidence which had either been destroyed, or very much weakened by the disastrous events of the war, was fully re-established. The extended transactions of the country required fresh facilities for carrying them on, and these were supplied in the utmost profusion. The number of banks, which in 1784 was certainly under 150, increased so rapidly, that in 1792 they amounted to about 350. In consequence, a banking office was opened in every market-town and in most considerable villages. And such being the case, it is needless, perhaps, to add, that the prudence, capital, and connections of those who set up these establishments were but little attended to. The great object of a large class of traders was to obtain discounts; and the bankers of an inferior description were equally anxious to accommodate them. All sorts of paper were thus forced into circulation, and enjoyed nearly the same degree of esteem. The bankers and those with whom they dealt had the fullest confidence in each other. No one seemed to suspect that there was anything hollow or unsound in the system. Credit of every kind was strained to the utmost; and the available funds at the disposal of the bankers were reduced far below the level which the magnitude of their transactions required to render them secure.

The catastrophe which followed was such as might easily have been foreseen. The currency having become redundant, the exchanges took an unfavourable turn in the early part of 1792. A difficulty of obtaining pecuniary accommodation in London was not long after experienced; and, notwithstanding the efforts of the Bank of England to mitigate the pressure, a violent revulsion took place in the latter part of 1792 and the beginning of 1793. The failure of one or two great houses excited a panic which proved fatal to many more. Out of the 350 country banks in England and Wales, when this revulsion began, about 300 were compelled to stop payments, and upwards of 50 were totally destroyed, producing by their fall an extent of misery and bankruptcy till then unknown in the country.

Attempts have sometimes been made to show that this crisis was not occasioned by an excess of paper money having been forced into circulation, but by the agitation caused by the war then on the eve of breaking out. But there does not seem to be any good grounds for this opinion. The symptoms of an overflow of paper—a fall of the exchange, and an efflux of bullion—took place early in 1792, or about twelve months before the breaking out of hostilities.

Suspension of Cash Payments in 1797.

The year 1797 is a most important epoch in the history of English banking. Owing partly to events connected with the war then carried on, to loans to the Emperor of Germany, to bills drawn on the treasury at home by the British agents abroad, and partly, and chiefly, perhaps, to the advances most unwillingly made by the bank to Government, which prevented the directors from having a sufficient control over their issues, the exchanges became unfavourable in 1795, and in that and the following year large sums of specie were drawn from the bank. In the end of 1796 and beginning of 1797, considerable apprehensions were entertained of invasion, and rumours were propagated of descents having been actually made on the coast. In consequence of the fears that were thus excited runs were made on the provincial banks in different parts of the country; and some of them having failed, the panic became general and extended itself to London. Demands for cash poured in from all quarters upon the bank, which, on Saturday the 25th of February 1797, had only £1,272,000 of cash and bullion in its coffers, with

every prospect of a violent run taking place on the following Monday. In this emergency, an order in council was issued on Sunday the 26th, prohibiting the directors from paying their notes in cash until the sense of Parliament should be taken on the subject. And after Parliament met, and the measure had been much discussed, it was agreed to continue the restriction till six months after the signature of a definitive treaty of peace.

As soon as the order in council prohibiting payments in cash appeared, a meeting of the principal bankers, merchants, traders, &c., of the metropolis, was held at the Mansion-house, when a resolution was agreed to, and very numerously signed, pledging, as had been done in 1745, those present to accept, and to use every means in their power to make bank-notes be accepted, as cash in all transactions. This resolution tended to allay the apprehensions that the restriction had excited.

Parliament being in session at the time, a committee was immediately appointed to examine into the affairs of the bank; and their report put to rest whatever doubts might have been entertained with respect to the solvency of the establishment, by showing, that at the moment when the order in council appeared, the bank was possessed of property to the amount of £15,513,690, after all claims upon it had been deducted. This suspension of cash payments being naturally followed by a withdrawal of gold from circulation, made it necessary to allow of the issue of notes of a smaller denomination than £5, and the statute of 1777 was accordingly also suspended.

Much difference of opinion has existed with respect to the policy of the restriction in 1797; but, considering the peculiar circumstances under which it took place, its expediency seems abundantly obvious. The run did not originate in any over-issue of bank paper, but grew entirely out of political causes. So long as the alarms of invasion continued, it was clear that no bank paper immediately convertible into gold would remain in circulation. And as the bank, though possessed of ample funds, was without the means of instantly retiring its notes, it might, but for the interference of Government, have been obliged to stop payments, an event which, had it occurred, might have produced consequences fatal to the public interests.

The error of the Government did not consist in their coming to the assistance of the bank, but in continuing the restriction after the alarm of invasion had ceased and there was nothing to hinder the bank from safely reverting to specie payments.

It had been generally supposed, previously to the passing of the Restriction Act, that bank-notes would not circulate unless they were immediately convertible into cash. But the event showed that this was not really the case. Though the notes of the Bank of England were not, at the passing of the Restriction Act, declared by law to be legal tender, they were rendered such in practice, by being received as cash in all payments on account of Government, and by the vast majority of individuals. For the first three years of the restriction, their issues were so moderate that they not only kept on a par with gold, but actually bore a small premium. But in 1801, 1802, and 1803, they were so much increased that they fell to a discount of from 8 to 10 per cent. In 1801 they again recovered their value; and from that year to 1808, both inclusive, they were at a discount of 2½ per cent. In 1809 and 1810, however, the directors appear to have embarked on a new course, and to have entirely lost sight of the principles by which their issues had previously been governed; for the average amount of bank-notes in circulation, which had not exceeded 17½ millions, nor fallen short of 16½ millions, in any one year, from 1802 to 1808, both inclusive, was in 1809 raised to £18,927,833, and in 1810 to £22,541,523. The issues of country bank paper were increased in a still greater proportion; and, as there was no corresponding increase of the business of the country, the discount on bank-notes rose from 2½ in 1808 to from 13 to 16 per cent. in 1809 and 1810.

This depreciation in the value of bank paper being accompanied by a corresponding fall in the exchange attracted the attention of the public and the legislature. In consequence, the House of Commons appointed, in 1810, a committee to inquire into the subject; and having examined several witnesses, the committee in their report, which was both an able and a celebrated paper, justly ascribed the fall in the value of bank paper, as compared with gold, to its over-issue; and recommended, in the view of correcting the existing evil and of preventing its recurrence, that within two years the banks should be obliged to resume specie payments. But this recommendation not being adopted, the over-issue of paper went on increasing. In 1812 it was at an average discount, as compared with bullion, of 20 per cent.; in 1813, of 23 per cent.; and in 1814, when the maximum of depreciation was attained, it was at 25 per cent.

At the period when the restriction on cash payments took place in 1797, it is supposed that there were about 280 country banks in existence; but so rapidly were these establishments multiplied, that they amounted to above 900 in 1813. The price of corn, influenced partly by the depreciation of the currency and the facility with which discounts were obtained, but more by deficient harvests and the unprecedented difficulties which the war threw in the way of importation, rose to an extraordinary height during the five years ending with 1813. But the harvest of that year being unusually productive, and the intercourse with the Continent being then also renewed, prices, influenced by both circumstances, sustained a very heavy fall in the latter part of 1813 and the beginning of 1814. And this fall having ruined a considerable number of farmers and produced a general want of confidence, such a destruction of provincial paper took place as has rarely been paralleled. In 1814, 1815, and 1816, no fewer than 240 country banks stopped payment; and *eighty-nine* commissions of bankruptcy were issued against these establishments, being at the rate of *one* commission against every *ten and a half* of the total number of banks existing in 1813.

The great reduction that was thus suddenly and violently brought about in the quantity of country bank paper, by extending the field for the circulation of Bank of England paper, raised its value in 1817 nearly to a par with gold. The return to cash payments being thus facilitated, it was fixed, in 1819, by the Act 59 Geo. III. c. 78, commonly called Sir Robert Peel's Act, that they should take place in 1823. But to prevent any future over-issue, and at the same time to render the resumption as little burdensome as possible, it was enacted, in pursuance of a plan suggested by Mr Ricardo, that the banks should be obliged, during the interval from the passing of the Act till the return to specie payments, to pay its notes, if required, in bars of standard bullion of not less than sixty ounces' weight. This plan was not, however, acted upon during the period allowed by law; for, a large amount of gold having been accumulated at the bank, the directors preferred recommencing specie payments on the 1st of May 1821.

The fluctuations, referred to above, in the value of paper were exceedingly injurious. From 1809 to 1815, the creditors of every antecedent contract, land-holders whose estates had been let on lease, stockholders and annuitants of every description—all, in short, who could not raise the nominal amount of their claims or incomes proportionally to the fall in the value of money, were to that extent losers. The injustice that would have been done to the creditors of the state and of individuals, who had made their loans

in gold, or paper equivalent to gold, by raising the denomination of the coin twenty-five per cent., however gross and palpable, would not have been greater than was actually done them in 1814, by compelling them to receive payment of their just debts in paper depreciated to that extent.

It is true, that after a currency has been for a considerable period depreciated, as much injustice is done by raising, as was previously done by depressing, its value. But there is good reason to doubt whether the depreciation from 1809 to 1815 (for the depreciation of 2½ per cent. during the six preceding years is too inconsiderable to be taken into account) extended over a sufficiently lengthened period to warrant the Legislature in departing from the old standard. It is needless, however, to offer any opinion on this rather difficult point, for we have seen that the value of paper was raised in 1816 and 1817 almost to par by accidental circumstances without any interference on the part of Government or of the bank. Sir Robert Peel's Act, to which this rise had been ascribed, not being passed till 1819, could have nothing to do with what occurred two or three years previously. Its object was twofold, to redeem the pledge given by Parliament to restore the old standard on the return of peace, and to shut the door against any fresh depreciation of paper.

History of Banking from the Resumption of Cash Payments to the Crisis of 1825.

The resumption of cash payments did not, however, put an end to the vicissitudes of banking. Notwithstanding the ample experience that had been supplied by the occurrences of 1792–93 and 1814–16, of the mischievous consequences of the issue of paper by the country banks, and of their want of solidity, nothing whatever was done, when provision was made for returning to specie payments, to restrain their issues, or to place them on a better footing. The consequences of such improvidence were not long in manifesting themselves. The prices of corn and other agricultural products, which had been greatly depressed in consequence of abundant harvests, in 1820, 1821, and 1822, rallied in 1823, and the country bankers immediately began to enlarge their issues. It is unnecessary to inquire into the circumstances which conspired, along with the rise of prices, to promote the extraordinary rage for speculation exhibited in 1824 and 1825. It is sufficient to observe, that in consequence of their operation, confidence was very soon carried to the greatest height. It did not seem to be supposed that any scheme could be hazardous, much less wild or extravagant. The infatuation was such, that even the most considerate persons did not scruple to embark in visionary and absurd projects; while the extreme facility with which discounts were procured upon bills at very long dates, afforded the means of carrying on every sort of undertaking. The most worthless paper was readily negotiated. Many of the country bankers seemed, indeed, to have no other object than to get themselves indebted to the public. And such was the vigour and success of their efforts to force their paper into circulation, that the amount of it afloat in 1825 is estimated to have been nearly 60 per cent. greater than in 1823. The consequences of this extravagant and unprincipled conduct are well known. The currency having become redundant, the exchanges began to decline in the summer of 1824. The directors of the Bank of England having unwarily entered, in the early part of that year, into an engagement with the Government to pay off such holders of 4 per cent. stock as might dissent from its conversion into a 3½ per cent. stock, were obliged to advance a considerable sum on this account after the depression of the exchange. But despite this circumstance, they might and ought to have taken measures, in the latter part of 1824 and the earlier part of 1825, by lessening their issues to stop the efflux of bullion. But not being sufficiently alive to the urgency of the crisis, the London currency was not materially diminished till September 1825. The recoil, which would have been less severe had the efforts of the bank to prevent the exhaustion of its coffers taken place at an earlier period, was most appalling. The country banks began to give way the moment they experienced a considerably increased difficulty of obtaining accommodation in London, and confidence and credit were immediately at an end. Suspicion having awakened from her trance, distrust had no limits. All classes of depositors made haste to call up the sums they had entrusted to the care of the banks. There was also a run upon them for payment of their notes, not in the view of sending the gold as a mercantile adventure to the Continent, but to escape the loss which it became obvious the holders of country paper would have to sustain. *Sauve qui peut* was the universal cry; and the destruction was so sudden and extensive, that in less than six weeks above seventy banking establishments were swept off, and a vacuum was created in the currency which absorbed from eight to ten millions of additional issues by the Bank of England, at the same time that myriads of those private bills that had previously swelled the amount of the currency, and added to the machinery of speculation, were wholly destroyed.

It may be worth while, perhaps, to observe that it has been alleged, in opposition to what is now stated, that the difficulties of the bank in 1825 were not caused by any excess either of its issues or of those of the country banks, but by the too great amount of the capital, that is of coin and bullion, it had lent; and in proof of this allegation, we are referred to the increase of nearly eight millions in the amount of securities which the bank held in August 1825 over their amount in August 1822, and to the simultaneous decrease of nearly six and a half millions in the amount of bullion in its coffers.[1] But a little consideration will suffice to show the futility of this statement. No issue of notes can be said to be in itself excessive. Whether it is or is not in excess depends upon its relation to the amount of coin and bullion reserved by the issuing bank in its coffers. The Bank of England enlarged its issues disproportionately and took no steps, or none of sufficient energy, to reduce the amount of notes in circulation till long after the exchange had become unfavourable, and bullion was demanded of it for exportation. The accumulation of securities was the necessary result of this radical error. The currency having become redundant in 1824, the notes of the bank were returned upon it for gold, so that its securities were augmented at the same time that its means of dealing with the unfavourable exchange were impaired. It is to be remembered, that the efflux of bullion showed conclusively that, however issued, and whether greater or less than at former periods, the paper afloat was in excess, and that its reduction had become indispensable. And such being the case, it was the duty of the bank directors, as soon as they felt the drain for gold setting steadily against them, to adopt every means in their power, by raising the rate of interest, selling securities, and otherwise, to reduce their issues, and restore

the exchange to par. And had they done this at a sufficiently early period, it is all but certain the bank would not have lost more than two or three millions of bullion; whereas, by their following a different line of conduct, and deferring the adoption of vigorous repressive measures till too late a period, it was drained of about seven millions of bullion, and its safety seriously compromised before it could stop the drain.[1]

Legislation of 1826—*Suppression of £1 Notes—Joint-Stock Banks of Issue authorized.*

Notwithstanding the fact that nations are slow and reluctant learners, the events of 1825-26, taken in connection with those of the same sort that had previously occurred, produced a conviction of the necessity of doing something that should at least improve the system of country banking in England. But the measures adopted with this view were very far indeed from effectually securing their object. The law of 1708, limiting to six the number of partners in banking establishments issuing notes, was repealed; and it was enacted, that banks with any number of partners might be established for the issue of notes anywhere beyond sixty-five miles from London, and that banks not issuing notes might be established in London itself with any number of partners. The circulation of notes for less than five pounds in England and Wales was at the same time forbidden. It was intended to extend the same prohibition to Scotland and Ireland, but the opposition to the proposal excited in these countries was too strong to be overcome. Sir Walter Scott threw himself zealously into the controversy, and by his *Letters of Malachi Malagrowther*, helped to make the resistance effectual.

The suppression of £1 notes was advantageous in shutting up one of the principal channels by which the inferior class of country bankers got their paper into circulation, to the frequent loss of the poorer classes; but it is now generally admitted that the balance of argument is in favour of the issue of notes of this denomination by the Bank of England or some agency of the state, under conditions ensuring their convertibility.

The second branch of the banking legislation of 1826 was for some time a comparative failure. Those who supposed that joint-stock banks would be immediately set on foot in all parts of England, were a good deal disappointed with the slowness with which they spread for some years after the Act permitting their establishment was passed. The heavy losses occasioned by the downfall of most of the joint-stock projects set on foot in 1824 and 1825, made all projects of the same kind be looked upon for a considerable period with suspicion, and deterred most persons from embarking in them. But this caution gradually wore off; and the increasing prosperity of the country, and the difficulty of vesting money so as to obtain from it reasonable return, generated anew a disposition to adventure in hazardous projects. A mania for embarking in speculative schemes acquired considerable strength in 1834; and during 1835 and part of 1836, it raged with a violence but little inferior to that of 1825. It was at first principally directed to railroad projects; but it soon began to embrace all sorts of schemes, and, among others, joint-stock banks, of which an unprecedented number were projected in 1835. The progress of the system was as follows:—

	Banks.
In 1826 there were registered	6
In 1827	1
In 1828	5
In 1829	4
In 1830	3
In 1831	8
In 1832 there were registered	10
In 1833	13
In 1834	8
In 1835	45
In 1836	11
Total	114

In point of fact, however, the number of banks created in 1835 and 1836 was vastly greater than appears from this statement. It seems that, at an average, each of the 56 banks established in those years, like those previously established, had from four to five branches; and as these branches transacted all sorts of banking business, and enjoyed the same credit as the parent establishment, from which they were frequently at a great distance, they were, to all intents and purposes, so many new banks; so that, instead of 56, it may safely be affirmed that from about 220 to 280 new joint-stock banks were opened in England and Wales in 1835 and 1836, but mostly in the former year.

In January, February, and March 1836, when the rage for establishing joint-stock banks was at its height, the exchange was either at par, or slightly in our favour, showing that the currency was already up to its level, and that if any considerable additions were made to it, the exchange would be depressed, and a drain for bullion be experienced. But these circumstances, if ever they occurred to the managers of the joint-stock banks, do not seem to have had, and could not in truth be expected to have, any material influence over their proceedings. Their issues, which amounted on the 26th of December 1835 to £2,799,551, amounted on the 25th of June 1836 to £3,588,064, exclusive of the vast mass of additional bills, cheques, and other substitutes for money they had put into circulation. The consequences were such as every man of sense might have foreseen. In April 1836 the exchange became unfavourable, and bullion began to be demanded from the Bank of England. The directors, that they might the better meet the drain, raised the rate of interest in June from 4 to 4½ per cent., and this not being enough sufficiently to lessen the pressure on the bank for discounts, they raised it in August from 4½ to 5 per cent. But during the whole of this period the country banks went on increasing their issues; and the issues of the joint-stock banks rose from £3,588,064 in June, to no less than £4,258,197 on the 31st of December, being an increase of nearly 20 per cent. after the exchange was notoriously against the country; and the most serious consequences were apprehended from the continued drain for bullion.

It may, perhaps, be supposed that the increased issue of the joint-stock banks would be balanced by a corresponding diminution of the issues of the private banks, and that on the whole the amount of their joint issues might not be increased. This, however, was not the case. Some private banks were abandoned in 1836, and others incorporated with joint-stock banks; and it is further true, that those which went on managed their affairs with more discretion than their associated competitors. But, from the 26th of September 1835 to the 31st of December 1836, the issues of the private banks were diminished only £159,087, whilst those of the joint-stocks were increased during the same period £1,750,160, or more than *ten times* the falling off in the others.

These statements show the inexpediency of leaving the issue of paper to the unregulated discretion of an indefinite number of competing banks. Its issue ought in all cases to be governed by the state of the exchange, or rather, as already stated, by the influx and efflux of bullion. But previously to 1844, the provincial banks might go on over-issuing for a lengthened period without being affected by a demand for bullion, or even for Bank of England paper.

[1] It may be observed that Mr McCulloch (on whose contributions to the seventh and eighth editions of this work the present article is based) pointed out in a paper in the *Scotsman*, published in 1825, what would be the inevitable result of the bank allowing the drain of bullion to run its course, viz., that it would be drained of its last sovereign, and obliged to stop payments; and that it could not avert this result otherwise than by narrowing its issues, and raising the value of the currency. The directors did this at last, but they ought to have done it nearly twelve months sooner.

In the end, no doubt, an efflux of the former was sure, by rendering money and all sorts of pecuniary accommodation scarce in the metropolis, to affect the country banks as well as the Bank of England; and then the injury to industry, occasioned by the withdrawal of their accustomed accommodations from a great number of individuals, was severe in proportion to the too great liberality with which they had previously been supplied. This was especially the case in 1836, when the Bank of England, by bolstering up the Northern and Central Bank, averted, though but for a while, the bankruptcy of that establishment, which had no fewer than forty branches, and, by doing so, is said to have prevented the occurrence of a panic that might have proved fatal to many other joint-stock and private banks. Still, however, the shock given to industrial undertakings, by the revulsion in the latter part of the year, and in 1837, although unaccompanied by any panic, was very severe. All sorts of commercial speculations were for a while completely paralyzed, and there were but few districts in which great numbers of individuals were not thrown out of employment. In Paisley, Birmingham, and most other towns, the distress occasioned by the revulsion was very general and long-continued. And owing to the Bank of England having delayed, in 1838 and the earlier part of 1839, to take efficient measures for the reduction of its issues, despite the unmistakable evidence of their being redundant, the bullion in its coffers was reduced in September 1839 to £2,406,000; and, but for the efficient assistance obtained from the Bank of France, its stoppage could hardly have been averted.

Act of 1844—*Objections to and Defence of that Act—Suspensions of in* 1847, 1857, *and* 1866.

This perilous experience having again forcibly attracted the public attention to the state of the banking system, Sir Robert Peel was induced to attempt its improvement. The clause in the Act 3 and 4 Will. IV. c. 9, which renewed the bank charter in 1833, gave Parliament power to revise or cancel it in 1845, and thus afforded a legitimate opportunity for the introduction of the new system. It was indispensable, in attempting to obviate the defects inherent in our currency, to proceed cautiously, to respect, as far as possible, existing interests, and to avoid taking any step that might excite the fears or suspicions of the public; but the measures which Sir Robert Peel introduced and carried through Parliament in 1844 and 1845, for the improvement of the English banking system, were so skilfully contrived as to provoke little opposition, at the same time that they effected most important and highly beneficial changes.

The measures in question consisted of the Act 7 and 8 Vict. c. 32, which refers to the Bank of England and the English country banks; and the Acts 8 and 9 Vict. c. 38, 37, referring to the banks of Scotland and Ireland. These statutes were intended to obviate the chances of over-issue, by limiting the power to issue notes payable on demand, and by making the amount of such notes in circulation vary with the amount of bullion in the possession of the issuers, and this object has been perfectly attained. The statutes have as completely failed to attain a second object contemplated by their author—that of preventing great and rapid fluctuations in the rate of discount; and the truth is now recognized, that the power of over-issuing notes is one of many causes which may conduce to variations in the rate of discount and by no means the most efficient of them. In dealing with the Bank of England, Sir Robert Peel adopted the proposal previously made by Lord Overstone,[1] for effecting a complete separation between the issuing and banking departments of that establishment, and giving the directors full liberty to manage the latter at discretion, while they should have no power whatever over the other.

The notes of the Bank of England in circulation for some years previously to 1844 rarely amounted to twenty, or sunk so low as sixteen millions. And such being the case, Sir Robert Peel was justified in assuming that the circulation of the bank could not, in any ordinary condition of society, or under any merely commercial vicissitudes, be reduced below fourteen millions. And the Act of 1844 allowed the bank to issue this amount upon securities, of which the £11,015,100 lent by the bank to the public was the most important item. Inasmuch, however, as the issues of the provincial banks were at the same time limited in their amount, and confined to certain existing banks, it was further provided, in the event of any of these banks ceasing to issue notes, that the Bank of England might be empowered, by order in council, to issue, upon securities, two-thirds, and no more, of the notes which such banks had been authorised to issue. Under this condition, the total secured issue of the bank has (1875) been increased from £14,000,000 to £15,000,000. *But for every other note which the issue department may at any time issue over and above the maximum amount* (£15,000,000) *issued on securities, an equal amount of coin or bullion must be paid into its coffers.* And hence, under this system, the notes of the Bank of England are rendered really and truly equivalent to gold, while their immediate conversion into that metal no longer depends, as it previously did, on the good faith, the skill, or the prudence of the directors. And these important results have been attained without imposing any burden of which any one has any right to complain. Our currency rests on the fundamental principle, that all debts above forty shillings shall be paid in gold. But individuals and associations, including the banking or commercial department of the bank, have the option, if they prefer it, to exchange gold for bank-notes, and to make use of the latter in their dealings with the public. Hence, if A or B goes to the issuers of paper, and gets 100 or 500 notes from them in exchange for an equivalent amount of gold, it is his own convenience he has exclusively in view. He was at full liberty to use gold, but he preferred exchanging it for notes because he could employ the latter more advantageously. This is the way in which paper is issued under the Act of 1844; and such being the case, it is contradictory to say that it is productive either of hardship or inconvenience.

It is alleged that the new system is injurious by shackling the bank in the use of its credit, and the answer is, that it does this in order to prevent the greater injury of over-issues of paper. The Act prevents the bank from issuing substitutes for money which do not represent money. It does not absorb or lock up a single sixpence worth of capital, nor does it interfere in any manner of way with its employment. The gold in the issue department of the bank was not purchased by the bank, and does not belong to it. The bank is its keeper, but not its owner. It belongs to the public, or to the holders of bank-notes, who deposited it in the bank in exchange for notes, with and under the express stipulation, that on paying the latter into the bank they should receive back their gold. Any interference with these deposits would be an interference with property held in pledge for others, that is, it would be an act precisely of the same kind with that which exposes private bailees to penal servitude.

But though the bank directors may not lay violent hands on the property of the public, the bank, it is obvious, has at this moment the same absolute command over its entire capital and credit, that it would have were the Act of 1844

[1] In tracts published in 1837 and 1840, and in his evidence before a committee of the House of Commons in the latter year.

non-existent. Apart from the practice of issuing transferable notes, the bank is free from all restraint, and is in precisely the same situation as other banking or mercantile establishments. Its directors may lend or not lend as they please, and may lay down such conditions as they please in regard to the interest and the terms of loans and discounts. In short, they may do whatever they like with their own; but farther they are not permitted to go. They may not substitute shadows for realities. They cannot, whether to assist others, or to relieve themselves from embarrassment, issue a single note except upon a deposit of bullion. But this rule does not operate on the bank only. It applies to all individuals and associations. And to relax it in any degree would be—disguise it as one may—to authorize an issue of fictitious or spurious paper, and consequently to vitiate the currency and to abuse credit in the way that is sure to be in the end the most disastrous.

This statement shows the groundless nature of the charge which is often made against the Act of 1844, that under its operation the bank runs the risk of being brought to a stop, though it may have some five, six, or even eight millions bullion in its coffers. For it is plain that two things are confounded in this charge, which are quite distinct, and have no necessary connection with each other, viz., the proceedings of the bank in the capacity of issuer of notes, and its proceedings in the capacity of a banking company. In the former capacity it is all but impossible that it should be brought to a stop; and if such a thing should happen, there would not then be an ounce of bullion in its coffers. It is not, however, impossible nor even very improbable, that the bank should be brought, in its mercantile capacity, into difficulties, while there may be a large amount of bullion in the issue department. But, though such should be the case, is that any reason why the bank directors should be permitted to draw on funds that do not belong to them, and over which they have no control? Supposing the bank was in difficulties, is it to be allowed to right itself by setting aside the principle of *meum* and *tuum*, and seizing on what belongs to others? The directors would be the first to repudiate such a doctrine, which must be rejected by all men who have any sense of honour or regard for character.

One of the most plausible objections to the Act of 1844 is that it "limits the currency;" that it makes no provision for the increasing demands of the public; and confines us in 1875, when the exports will probably exceed 220 millions, to the same amount of money as in 1844, when the exports did not exceed 58½ millions. The simple truth, however, is that the Act allows money to be imported and exported, to be retained or sent elsewhere, just as it is wanted, and what it does limit is the uncontrolled issue of paper representatives of money, which experience proved were too often emitted without any reference to the reserves of money kept to maintain the convertibility of the paper issued. The £14,000,000 (now £15,000,000) issued on securities is the only thing that is limited in the Act; everything else varies with the varying condition and circumstances of the country, including the means by which the use of money may be economized. In the week ending the 7th July 1875, the issue department of the bank had issued notes to the amount of £41,029,955, being no fewer than £26,029,955 over and above the amount authorized to be issued on securities. And if the country had really required a larger supply of money, that is, if more coins, or paper equivalent to coins, could have been absorbed into the circulation without rendering the currency redundant, and depressing the exchange, the additional quantity would have been forthwith supplied. For, under such circumstances, merchants, bankers, and money-dealers, would have realized a certain and immediate profit by carrying bullion to the mint or the bank, that they might obtain coins, or notes, or both, with which to increase the currency. It is one of the chief merits of the Act of 1844, that, under its agency, the supply of money is not to any extent or in any degree regulated or influenced by the proceedings of the bank or the Government. They have nothing to do in the matter, unless it be to coin the bullion which individuals or firms carry to the mint for that purpose, and to exchange, when called upon, notes for coins, and coins for notes. The supply of money, like that of all non-monopolized articles, is wholly dependent upon, and is determined by the free action of the public. It would, indeed, be quite as true to say, that the Act of 1844 limits the amount of corn, of cloth, or of iron produced in the country, as that it limits the amount of money. It maintains the value of the notes issued by the bank on a level with the coins for which they are substitutes; but beyond that its effect is *nil*. It has nothing whatever to do with the greater or less amount of the coin and notes of trustworthy convertibility put into circulation. That depends entirely on the estimate formed by the public of its excess or deficiency, an estimate which when wrong is sure to be corrected by the exchanges.

We may add, that no inference can ever be safely drawn from the number of notes or coins, or both, afloat in a country, as to whether its currency be, or be not, in excess. That is to be learned by the state of the exchange, or by the influx and efflux of bullion. If the imports of bullion exceed the exports, it shows that the currency is in some degree deficient; while, if the exports exceed the imports, it shows that the currency is in excess, and that no additions can be made to it without farther depressing the exchange and increasing the drain of bullion. When the imports and exports of bullion are about equal, then of course the currency is at about its proper level. These are the only criteria by which anything can ever be correctly inferred in regard to the deficiency or excess of currency. Its absolute amount affords hardly even a basis for conjecture. When there is little speculation or excitement, an issue of 25 or 27 millions bank-notes may be in excess; while, at another time, and with a different state of trade and speculation, an issue of 35 or 37 millions of notes may not be enough. Except in periods of internal commotion, or when we are disturbed by alarms of invasion, the state of the exchange is the only, as it is the infallible, test of the sufficiency and insufficiency of the currency. We may further state, that those who are in the habit of complaining of the limitation of the currency by the Act of 1844, almost uniformly underrate its amount. We have already seen that, in the week ending the 7th July 1875 the notes issued by the issue department of the bank amounted to £41,029,955, and of these £12,453,415 were in the banking department of the bank, leaving a balance of £28,576,540 in the hands of the general public; and this latter sum is, we are told, the real amount of the issues. But this is falling into the rather serious blunder of mistaking a part for the whole. The notes in the banking department of the bank make not only a part, but a most important and active part, of the currency of the country. They constitute the means, along with the bullion in the same department, with which the bank carries on her banking business, and are as evidently a portion of the currency as the notes in the tills of private bankers and the pockets of individuals. The notes in the banking department of the bank must therefore never be omitted in estimating the amount of notes in circulation. The latter, and the notes out of the issue department, are identical; and, in a general point of view, it matters not a straw whether they are in the hands of the banking department of the bank or of individuals.

So far we have dealt with the legislation of 1844 in its bearing on the Bank of England. The desire of Sir Robert Peel reached beyond this, but he was unable to complete his policy. He rightly held that experience had shown that the balance of advantages lay on the side of the suppression of all note issues except that of the Bank of England, as reformed by him, or of some similar supplementary establishments regulated in the same manner. But it was obviously impossible to prohibit, without compensation, the future exercise by country bankers of the rights they had legitimately acquired; and as it was not easy to buy up the existing privileges of the private and joint-stock banks, Sir Robert Peel allowed them to remain under conditions prohibiting their extension, and he apparently hoped that country issues would gradually disappear before the rivalry of Bank of England notes. The Act of 1844, accordingly, enacted that no new bank for the issue of notes should be established in any part of the United Kingdom; and that the *maximum* issue of notes by the existing country banks of England should in future be limited to the average amount which they had respectively in circulation during the twelve weeks preceding the 27th April 1844. It was also ordered that the names of the partners in joint-stock and other banks should be periodically published. A provision was also enacted under which an issuing bank could resign its privilege by composition with the Bank of England. The existing law was maintained preventing the issue of any notes other than the Bank of England in London, and the establishment, within sixty-five miles of London, of any branch of an English joint-stock bank having the privilege of issue.[1]

The convertibility of the Bank of England notes has been perfectly maintained since 1844, and the management of English banks, whether private or joint-stock, has been sound and judicious, the cases of failure among them being few and contrasting strongly with the recurrent epidemics of insolvency of earlier experience. It must, however, be admitted that the variations in the rate of discount charged by the bank have been much more numerous and violent since 1844 than they were before, and on three occasions—in 1847, 1857, 1866—it has been judged necessary to authorize a suspension of the Act so far as to allow the bank directors the power to strengthen the banking department by recourse to the reserves of the issue department. In each case the suspension of the Act arrested and allayed the panic prevailing up to the moment of suspension, and in 1866 it was not, in fact, found necessary to exercise the power to borrow from the issue department which had been conceded to the directors. We must proceed to inquire whether the Act of 1844 is to be blamed for the increase in the number of changes of the rate of discount which has since been experienced, and whether this increase and the suspension of the Act in time of trial constitute a reason for its abrogation or for a modification of its provisions.

In the first place, the increased number of changes in the rate of discount is more apparent than real. The management of the Bank of England has become responsive to the movement in the value of money in the open market in a degree unknown before this generation. The rate of discount outside the bank changed rapidly and often before 1844, but its fluctuations were to a large extent prevented from affecting the Bank of England. Previously to the modification of the Usury Laws in 1839, the bank could not charge more for loans than 5 per cent., and for some considerable period after the restriction had been removed the directors, influenced, in part at least, by their accustomed habit on several occasions, permitted the bank to be involved in difficulties which might have been averted by their sooner raising the rate of discount. Strict limitation in the number and class of customers with whom the bank would do business, and a refusal to rediscount bills that had been already discounted by money-dealers, made it possible to keep the bank rate below the rates of the open market without exposing the resources of the establishment to an exhausting demand.

Next, it is to be observed that the methods of economizing the use of money by the development of banking have been extraordinarily multiplied since 1844. The Bank Act, as we have shown, in no way operates to diminish the supply of money in the country; on the contrary, it tends to increase it, since it forbids any extension of the use of notes issued on credit as a substitute for money. The effect of the Act has therefore been to neutralize rather than to stimulate the process of economy in the use of money to which we have called attention. But the transactions of bankers—the issue of cheques, the negotiation of bills, &c., &c.—have multiplied out of all proportion to the stock of ready money on which they rest, and the mass of transitory credits being constantly increasing while the reserves of cash suffers little change, there naturally and necessarily follows an increased sensibility in the equilibrium of the money market, with constant oscillations in the rate of interest. But although the increase in the number of changes of discount since 1844 has not been as great as may at first seem apparent, and so far as the increase has been real it must be chiefly attributed to the growing disproportion between the magnitude of transitory credits at any time existing and the reserve of cash kept on hand, yet it may be freely admitted that it is not improbable that changes have from time to time happened that might not have occurred supposing the separation of the banking and issue departments had not been established. It is evident that if the cash in the two departments had been equally accessible to the bank directors, a withdrawal of money which is now thrown upon one department would not have caused so great a change in the proportion between liabilities and reserve as is now exhibited; and if the directors had reason to believe that the withdrawal was no more than a temporary efflux to the provinces or elsewhere, to be followed by a speedy reflux, they might have been bolder in abstaining from raising the rate of discount. But this action or rather inaction would have been indulged in at the price of a certain risk to the convertibility of the note, which is now avoided, and if it should appear in the end that the directors had erred in supposing the movement of money to be but temporary, they would see reason to regret that they had not been forced to stringent action at the beginning of it. The oscillations experienced in the rate of discount, oscillations which after all indicate nothing more than the natural movement in the value of a medium which is the first to be agitated by changes in value of every other commodity, are cheaply purchased as the price of the permanent and perfect equality of the bank-note and the money it represents. The repeated suspensions of the Act of 1844 in time of trial do, *prima facie*, present a much stronger argument for the repeal of the statute. Legislation which breaks down upon critical occasions discredits the Legislature that decreed it; and it is not to be denied that the mere suspension of the Act has more than once operated as a charm to allay feelings of panic among bankers, money-dealers, and merchants. It must also be admitted that Sir Robert Peel, in common with the earlier advocates of the policy of the Act, believed that it would prevent the recurrence of commercial crises. It is strange that such an anticipation should have been entertained. Whoever will reflect on the nature of the organization of credit in the commercial world, and on the timid and self-

[1] The provisions regulating the issues of Scotch and Irish banks will be found below, p. 332 *sqq*.

protecting instincts of men, especially of capitalists, will be forced to confess that the recurrence of crises must be accepted as inevitable. The more highly developed is the economy of money the greater must be the sum which banks and bankers are liable to be called upon to repay on demand or at short notice in proportion to the reserves of money kept in their coffers; and the greater also must be the amount of bills falling due daily, and largely met as they fall due by the proceeds of bills drawn daily and discounted as drawn. The smoothness of action of the commercial machine evidently depends upon the continuance of that confidence which is ordinarily felt by the creditor-class in the solvency of debtors, and any access of distrust may easily produce consequences culminating in a crisis. Bankers who are at once debtors and creditors are necessarily constrained to protect themselves in such periods of defective confidence by declining to meet the applications for loans and discounts which are forced upon them; and a sharp competition ensues for the possession of the ready money that is available in the market. The pressure is concentrated upon the Bank of England, and the publicity of the condition of that institution, consequent upon the weekly issue of its balance-sheet, lets all men know the rate of decline of its cash reserve. At such a time an accident may cause the spirit of caution to pass into apprehension and panic. The fear that the cash balances of the banking department may be exhausted incites bankers to hasten to anticipate one another in withdrawing any reserve they may have kept at the bank, and the rate of diminution of the cash of the department is accelerated. It is obvious that the condition we have described is in its origin independent of any particular regulations adopted with respect to the note-circulation of a community; and it has, in fact, been experienced in Great Britain under all varieties of laws, and in the United States, in Northern and Southern Germany, and in the British colonies under an equally wide dissimilarity of currency-regulations. Our history previous to 1844 shows that such a condition may be aggravated, if not precipitated, by an antecedent issue of notes increasing the proportion between the volume of transitory credits and the cash available to meet instantaneous demands; and as long as the issue of notes was unrestricted, bankers could never resist the temptation to make up, by an increase in their issues, any diminution in their available cash, a cause directly provocative of a further diminution by its effect on adverse exchanges, and therefore producing a sharper reaction when the necessity was at last recognised of recovering the balance between their cash in hand and their liabilities. The Act of 1844 cannot prevent panic, but it prevents bankers from resorting to causes which aggravate panics, and it moreover supplies a means of allaying the unreasoning terror in which panics culminate. Were it not for the separation of the issue and the banking departments we should be constrained to witness and tolerate periodical suspension of cash payments, as this would be the only means left of appeasing alarm; and this desperate expedient has been, in fact, employed over and over again, under such circumstances, both in England and elsewhere. The Act of 1844 gives us a less dangerous, though by no means a perfectly harmless, power. When the minds of creditors are unhinged, and all are competing for money which is not in existence in sufficient quantities to satisfy their demands, the announcement that the Government has authorized the bank directors to suspend the action of the Act and to fall back on the resources of the issue department operates as a charm. The mere announcement is often enough to put an end to the panic previously prevailing, the feverish fit passes away, and the customary temper of confidence is more or less slowly restored.

We conclude that the existence of the Act of 1844 is justified even when it is suspended, for it provides, in the maintenance of the cash reserves of the issue department, a stock of money, the unlocking of which furnishes the means of arresting panic which would otherwise have to be sought in a periodic suspension of cash payments. It has naturally been asked whether the law might not be saved the apparent discredit involved in its being set aside by an act of the Executive Government, acting on the faith of a subsequent indemnity from Parliament, by the embodiment in it of a power authorizing its suspension under circumstances that provoke its suspension. Mr Lowe, as Chancellor of the Exchequer, introduced into the House of Commons, in 1873, a bill having this object. He proposed that the Bank Act might be suspended by order of the Government of the day when the *minimum* rate of discount had reached 12 per cent., when the exchanges were favourable to England, and when the governor and deputy-governor of the bank certified that panic had caused a large portion of the bank notes nominally in circulation to be locked up and withdrawn from circulation. The authority of Mr Gladstone's administration had declined when this bill was introduced, and it was not well received. It was contended that the conditions proposed by Mr Lowe had not always existed when the Act had been suspended, and they would be so rarely satisfied that the power of suspension promised by the bill could never be exercised. It was further contended that Mr Lowe's attempt was necessarily impracticable. In seeking to define beforehand the conditions of suspension of the Bank Act, he tried to define the conditions of a panic; and to attempt to define the conditions of that which is in its essence unreasonable was a logical contradiction. A panic has no laws: it has no fixed shape. It is precipitated we know not how; and we are in the midst of it before we are aware. As it is thus impossible to prescribe beforehand the conditions of panic, it may reasonably be thought that it is better to leave to the Government of the day the responsibility of acting when a panic has demonstrated its existence. Mr Lowe's bill, assailed from many quarters, was withdrawn without the opinion of Parliament being taken on its merits, and no attempt has been since made to bring the subject before the Legislature.

We have already said that Sir Robert Peel contemplated an ultimate extinction of all note issues save that of the Bank of England; and he probably expected that the substitution of Bank of England notes for all others would not be long delayed. The progress actually achieved towards this end has been very slow. Out of 204 private banks in England and Wales left by the Act of 1844, with total privileged issues of £5,153,407, no more than 85 have ceased to issue; and the amount they issued which is now withdrawn was £1,283,041. Of joint-stock banks 18 have ceased to issue £842,453, out of 72 having privileged issues of £3,495,446. Only one Scotch bank has ceased to issue notes since the Scotch Act of 1845, and no alteration whatever has taken place in the fixed issues of the Irish banks. It may be added that the provisions of the Act of 1844, relied upon by Sir Robert Peel for bringing about by arrangement a substitution of Bank of England notes for those of privileged bankers, have been for many years entirely neglected. With these facts before us it is not surprising that, in 1865, Mr Gladstone, as Chancellor of the Exchequer under Lord Palmerston, should have submitted to the House of Commons a bill dealing with the subject. By it, it was proposed that private banks of issue in England and Wales should be released from the existing restriction that the numbers of partners must not exceed six, and that joint-stock banks should be allowed to come within the circle of sixty-five miles from London upon their

undertaking to pay annually to the Exchequer a duty at the rate of 2 per cent. (altered in committee on the bill first to 1½ and then to 1 per cent.) on their average issues, and that thereupon their privileges of issue should be assured to them until 1890 (altered in committee to 1875 and 1880), after which these privileges should cease and determine. The bill was purely permissive; but it was thought by its author that a large proportion of the English banks of issue would place themselves under its operation, and further legislation would be practicable with respect to the rest. The bill, however, was less and less approved as it became better known, and it was ultimately withdrawn. From that time no legislation on the subject has been contemplated until the session 1875, when the action of the Scotch banks in establishing head offices in London was followed by an agitation described in the section on Scotch banks (p. 332), which has resulted in the appointment of a select committee on the law of banking and of note issues.

The Select Committee thus appointed has received a vast mass of evidence on the law and practice of banking and of the issue of notes, but the session has been allowed to close without any attempt being made to report on the subject of the committee's inquiries, and no practical action is expected to follow the termination of its labours. It must be admitted that the obstacles to legislation, supposing legislation to be desirable, are considerable. The bankers of the kingdom are largely represented on both sides of the House of Commons, and they are on the whole well contented with the present state of the law, while the great body of the public are profoundly ignorant and uninterested in it. The inaction to be overcome is so great, and the force available is so limited, that nothing will be done except under the influence of a commercial crisis, when almost anything may be done. The aim of economists and statesmen should be to produce a body of authority that may command respect even in the midst of universal agitation; and the inquiries of the Select Committee to which we have referred might be useful for this purpose, if they had been pursued with any discrimination. As it is, the evidence received by the committee will probably serve as a quarry to which wisdom and unwisdom may equally resort for facts and arguments.

At the risk of stating something that may appear too obviously true to require statement, we would submit that the question, whether bankers should be permitted to issue notes, must be determined upon a balance of opposing considerations of expediency. Many of the advocates and supporters of Sir Robert Peel's legislation of 1844 have said, apparently with a conviction that they were expressing an axiomatic truth, that the issue of notes was no part of the business of a banker. Mr. Gladstone has, within the past session, spoken in this sense. The force of assertions of this kind cannot be admitted. There is no law of nature limiting the action of a banker within the bounds sought to be prescribed; and if we accept as the definition of a banker a person whose business it is to borrow and lend money, we cannot but recognize in the issue of transferable notes a most convenient process of carrying on this business. A banker who issues notes borrows so much from the persons from time to time holding them, and this money he has lent to the customers indebted to him. The reasons of convenience which justify a prohibition of the liberty of issue are, first, that experience has shown that this process of borrowing is too potent and too easily abused to the precipitation and aggravation of commercial crises; and, secondly, that the great and almost insuperable difficulty of refusing to receive notes which have obtained general currency makes it most desirable that such notes should possess some better guarantee than can be always forthcoming of the solvency of private issuers. These are the reasons which prevail to uphold Sir Robert Peel's legislation, and which impel us to consider what means may be discovered of perfecting his policy by the unification of issues throughout the kingdom.

We believe the propagation of clear ideas on the subject of the note currency, and the acceleration of the time when one currency only shall be in circulation, would both be greatly facilitated by a mechanical and local separation of the issue department from the Bank of England. Much confusion of thought still prevails by reason of the fact that the Bank of England is used as the agent for managing what is now a state issue, resting, so far as it is uncovered by specie, upon state security. If the business of issuing notes were removed bodily from the Bank of England and located in a Government office, and the name of the notes at the same time changed, it could not fail to be seen that the business left behind in Threadneedle Street differed in no essential particular from that of any other banker in Lombard Street, and much of the superstitious regard of the City for the Bank of England, and trust in its assistance in time of trouble, would be rapidly destroyed. It would then be understood that the cry for ministerial interference at the time of crises and of incipient crises was nothing more than a claim for the nation to cover with its credit those who had not been prudent enough to maintain adequate reserves for their own defence; and, as this would be understood beforehand, it would induce the consequence of greater circumspection on the part of dealers in money and a less temptation to rely on extraneous aid. The purely mechanical act of removing the issue of notes from Threadneedle Street would make the facts of the situation plain, and would bring about an alteration of conduct among London bankers, so that it should conform to the facts thus perceived. It has for some time past been clearly perceived that the delicacy of the condition of the money market in London has been much exaggerated, and the feverish tendency to crises materially excited, because the cash reserves kept by the London bankers are disproportionately small compared with the amount of their instantaneous liabilities. Competition has, of course, been a considerable element in causing this attenuation of cash reserves. Each joint-stock bank has struggled after that increase of credit which follows an increase of dividends; and the unproductive cash balances on hand have been kept down to the lowest limit. They would, however, never have been reduced to such narrow dimensions but for the reliance placed on the assistance of the Bank of England in the last extremity; and if it were made plain that the Bank of England is itself nothing more than a big joint-stock bank, this reliance would disappear. Many schemes, equally ingenious and chimerical, have been recently put forth for compelling bankers to keep larger reserves of cash in proportion to their deposits. The true way to remove the danger always threatening us under the system that exists is to produce a conviction among bankers that they must not expect help elsewhere if they become distressed through a default in their own reserves of cash.

If the separation of the issue department from the rest of the Bank of England was completed by its transfer to a Government office under the management of State agents, the unification of the issues of the kingdom might be accomplished by legislation akin to that adopted by the United States in relation to the national banks. Each bank of issue might be required to withdraw its own notes and to receive and put out in exchange for them notes emanating from the State establishment, but bearing a statement on their face of the banks through which they were issued. Government securities should be deposited by

the issuing banks for the amounts thus put into circulation, which must not exceed the amount of their existing authorized issues; and the interest on these securities would be paid to the banks, less a fixed charge to defray the cost of preparing and issuing the notes delivered to them. The notes thus issued would be payable at the central State office, and would circulate throughout the kingdom; but as often as they were brought back to the central office they would be cleared again by the several issuing banks for reissue, unless the latter desired to retire from the arrangement, in which case the issuing bank would redeem the notes it issued, which would be cancelled, and the securities deposited, or a corresponding part of them, would be handed back. It would not be improper to force this plan on the acceptance of the privileged banks of issue, although we believe it would be freely accepted, inasmuch as their notes would at once acquire currency throughout the kingdom without discrimination of locality in exchange for the deposit of security, and the gain they now realize from the issue of notes would be left undiminished. We must, however, repeat the expression of the conviction that neither this nor any other change of the present system can be regarded as practicable until the impulse of agitating circumstances has stirred up Parliament to face the question.

Different Species of Banks—The Clearing-house—Authorization of Banks with Limited Liability.

We have elsewhere hinted at the subdivision of the business of banking which has accompanied the development of commerce. A banker borrows and lends money, but the conditions under which money is borrowed or lent may be extremely various, and the different classes of bankers are distinguished from one another by differences in the rules which they observe in borrowing or lending. Bankers may borrow money on call, at deposit, on debentures, at interest, or without interest, and they may lend on open credits, by discounting bills, by advances on mortgage repayable in instalments or otherwise, &c., &c.

Banks of Deposit.—These banks receive money on deposit, that is to say, on conditions that a certain prescribed notice shall be given of the time of withdrawal. They allow interest, and they usually lend a large proportion of their money on securities which are not at any moment immediately capable of being realized.

Land Mortgage Banks may be classed with banks of deposit, but they are also accustomed to borrow on debentures repayable at the end of one, two, three, or a larger number of years, at rates of interest varying with the period of the debenture. These institutions were first started for the purpose of granting facilities to the mortgagers of land. The money received on debentures was lent out again to proprietors and purchasers of land, who repaid their debts by annual instalments. It was in this way that the legislation of Stein was facilitated in Germany; the peasant being able to obtain at once from the Land Mortgage Bank the capital necessary to redeem the feudal rights of his lord, a debt which he repaid by a series of annual payments often corresponding to what he had previously paid as rent, until he became an absolutely unincumbered owner of the fields he cultivated.

Credit Companies, such as the *Crédit Foncier*, the *Crédit Mobilier*, &c., &c., are strictly analogous to land mortgage banks, except that they invest their funds in loans on the security of general industrial undertakings, to which business they have added the function of negotiators of direct loans between companies formed for the conduct of such undertakings and the capitalist public.

Discount Banks and *Discount Agencies* borrow money on call or deposit, and lend it exclusively in the discount of bills and negotiable securities, which they often rediscount with capitalists desirous of investing their money in forms capable of being speedily realized.

Trust Associations borrow money on debentures and invest it in the loans of foreign states or similar securities,—the principle of such an association being that the original investor can be secured against the default of any one borrower by the receipt of a high average rate of interest and the general solvency of the rest.

Savings-Banks are institutions established for the receipt of the smaller savings of the poor. As at present existing they are divided into two classes, the Trustees' Savings-banks and the Post Office Savings-banks; but it seems probable that some rearrangement of their machinery will be made in the next session of Parliament. For further particulars see SAVINGS-BANKS.

Allusion has already been made (*ante*, p. 316) to the Clearing-house. This institution was established, just a century ago, as a place where the clerks of the bankers in the City of London could assemble daily to exchange with one another the cheques drawn upon and bills payable at their respective houses. Before the Clearing-house existed, each banker had to send a clerk to the places of business of all the other bankers in London to collect the sums payable by them in respect of cheques and bills; and it is obvious that much time was consumed by this process, which involved also the use of an unnecessary quantity of money and corresponding risks of safe carriage. In 1775 the common centre of exchange was agreed upon. Its use was confined to the bankers,—at that time and long afterwards exclusively private bankers,—doing business within the City, and the bankers in the west end of the metropolis used some one or other of the City banks as their agent in clearing, a practice which still continues. When the joint-stock banks were first established the jealousy of the existing banks was powerful enough to exclude them altogether from the use of the Clearing-house; and some years elapsed before this feeling was removed so as to allow them to be admitted.

At first the Clearing-house was simply a place of meeting, but it came to be perceived that the sorting and distribution of cheques, bills, &c., could be more expeditiously conducted by the appointment of two or three common clerks to whom each banker's clerk could give all the instruments of exchange he wished to collect, and from whom he could receive all those payable at his own house. The payment of the balance settled the transaction, and an analysis of the statistics of the Clearing house by the late Mr Babbage (*Jour. Statist. Soc.*, March 1856) shows that the amount of cash that passed was often less than 4 per cent. of the total sums cleared. Latterly, however, the arrangements of the Clearing house have been further perfected, so that neither notes nor coin are now required. The Clearing house, as well as each banker using it, has an account at the Bank of England, and the balances due at the close of each day's transactions are settled by transfers from one account to another at the bank.

The use of the Clearing-house was still further extended in 1858, so as to include the settlement of exchanges between the country bankers of England. Before that time each country banker receiving cheques on other country bankers sent them to those other bankers by post (supposing they were not carrying on business in the same place), and requested that the amount should be paid by the London agent of the banker on whom the cheques were drawn to the London agent of the banker remitting them. Cheques were thus collected by correspondence, and each remittance involved a separate payment in London. In 1858 it was proposed to set up a country clearing-house in

London; but it was suggested by Sir John Lubbock that the existing establishment could accomplish what was desired, and this was eventually done. A country banker now sends cheques on other country banks to his London correspondent, who exchanges them at the Clearing-house with the correspondents of the bankers on whom they are drawn. (Sir John Lubbock, *Jour. Statist. Soc.*, Sept. 1865.) It will be easily understood that an extraordinary economy in the use of coin has resulted from these arrangements; and in the paper by Sir John Lubbock to which we have referred, he gives statistics showing that out of the sum of a million paid into the bank in which he is a partner, only £21,500 consists of bank-notes and £6210 of coin. An ordinary weekly clearing varies from 100 to 130 millions; in 1868 the weekly average was, however, no more than £65,397,075, from which it rose continuously to an average of £116,254,717 in 1873. There was a little falling off in 1874, which is now being recovered.

Up to the year 1858 banking companies could not be constituted with limited liability of partners except by way of privilege under special Acts of Parliament, Royal Charters, or Letters Patent; and although the Bank of England, and the three oldest established banks in Scotland, were thus favoured without any consequent deterioration in the character of their management, abundant arguments were adduced in deprecation of a general law on the subject. In 1858, however, an Act was passed authorizing the formation and registration of banking companies with limited liability, and also enabling existing unlimited companies to register as associations with a limited liability of partners, subject to a proviso that, if the bank was a bank of issue, the liability of its partners should remain unlimited in respect of such issue. Several banks have been established and registered under this law, and no evil results have been observed to follow.

Present Management of the Bank of England.

When the charter was renewed in 1833, the notes of the Bank of England were made legal tender everywhere in England except at the bank. Of the wisdom of this regulation no doubt can be entertained. Bank-notes are necessarily always equivalent to bullion; and by making them substitutes for coin at country banks, the demand for the latter during periods of alarm or runs is materially diminished, and the stability of the bank and of the pecuniary system of the country proportionally increased.

Since 1826 the bank has established branches in some of the great commercial towns. The mode and terms of conducting business at these have been described as follows:—

"The branch bank at Swansea [and the same is true of those established in other places] is to be a secure place of deposit for persons having occasion to make use of a bank for that purpose; such persons are said to have *drawing accounts:* to faciliate to the mercantile and trading classes the obtaining discounts of good and unexceptionable bills, founded upon real transactions, two approved names being required upon every bill or note discounted; these are called *discount accounts*. The applications of parties who desire to open discount accounts at the branch are forwarded to the parent establishment for approval, and an answer is generally received in about ten days. When approved, good bills may be discounted at the branch without reference to London. Bills payable at Swansea, London, or any other place where a branch is established, are discounted under this regulation. The dividends on any of the public funds, which are payable at the Bank of England, may be received at the branch by persons who have opened 'drawing accounts,' after signing powers of attorney for that purpose, which the branch will procure from London. No charge is made in this case, except the expense of the power of attorney and the postages incurred in transmitting it. Purchases and sales of every description of Government securities are effected by the branch at a charge corresponding to that made by the local bankers where the branch is situated. A commission, including brokerage in London, and all expenses of postage, is charged on paying at the Bank of England bills accepted by persons having drawing accounts at Swansea, such bills to be advised by the branch; also for granting letters of credit on London, or on the other branches. The branch grants bills on London, payable at seven days' date, without acceptance, for sums of £10 and upwards. Persons having drawing accounts at Swansea may order money to be paid at the bank in London to their credit at Swansea, and *vice versa*, at a charge of 6d. in lieu of postage. The branch may be called upon to change any notes issued and *dated* at Swansea; but they do not change the notes of the bank in London, nor receive them in payment, unless as a matter of courtesy where the parties are known. Bank post bills, which are accepted and due, are received at the branch from parties having drawing accounts, and taken to account without any charge for postage; but unaccepted bank post bills, which must be sent to London, are subject to the charge of postage, and taken to account when due. No interest is allowed on deposits. No advance is made by the branch upon any description of landed or other property, nor is any account allowed to be overdrawn. The notes are the same as those issued by the parent establishment, except being dated Swansea, and made payable there and in London. No note issued exceeds the sum of £500, and none are for a less amount than £5."

The Bank of England transacts the whole business of Government. "She acts not only," says Adam Smith, "as an ordinary bank, but as a great engine of state. She receives and pays the greater part of the annuities which are due to the creditors of the public; she circulates Exchequer bills; and she advances to the Government the annual amount of the land and malt taxes, which are frequently not paid till some years thereafter."

The Bank of England rarely discounts bills that have more than two, or at most three months to run, and it were well were this rule generally observed by other establishments. The discounting of bills at long dates is a powerful stimulus to unsafe speculation. When individuals obtain loans which they are not to be called upon to pay for six, twelve, or, perhaps, eighteen months, they are tempted to adventure in speculations which are not expected to be wound up till some proportionally distant period; and as these not unfrequently fail, the consequence is that, when the bills become due, there is commonly little or no provision made for their payment. In such cases the discounters, to avert an imminent loss, sometimes consent to renew the bills. But, while a proceeding of this sort is rarely productive of ultimate advantage to either party, the fact of its having taken place makes other adventurers reckon that, in the event of their speculations proving to be less successful than they anticipated, their bills will be treated in the same manner, and thus aggravates and extends the evil.

In other respects, too, the discount of bills at long dates, or their renewal, or the making of permanent loans, is altogether inconsistent with sound banking principles, for it prevents the bankers from having that command over their resources which is advantageous at all times, and indispensable in periods of difficulty or distress.

In the discounting of bills, a great deal of stress is usually laid, or pretended to be laid, on the distinction between those that arise out of real transactions and those that are fictitious or that are intended for accommodation purposes. The former are said to be legitimate, while the latter are stigmatized as illegitimate. But Mr Thornton [1] has shown that the difference is neither so well marked nor so wide as many suppose. A notion seems to be generally entertained that all real bills are drawn against produce of one sort or other, which (or its value) is supposed to form a fund for their payment. Such, however, is not always, nor even most commonly, the case. A, for example, sells to B certain produce, for which he draws a bill at sixty days' date. But prices are rising, trade is brisk, or a spirit of speculation is afloat, and, in a week or two (sometimes much less), B sells the produce at an advance to C, who thereafter sells it to D, and so on. Hence it may, and, in fact, frequently does happen, that bills amounting to

[1] On the Paper Credit of Great Britain, cap. 2.

four, five, or even ten times the value of a quantity of merchandise, have grown out of its successive sales, before the first bill of the series has become due. And not only this, but bills are themselves very frequently rediscounted; and in this case the credit of the last endorser is generally the only thing looked to; and there is not, perhaps, one case in ten in which any inquiries are made in regard to the origin and history of the bills, though they are often of the most questionable description.

On the whole, therefore, it would seem that the real or presumed solvency of the parties signing a bill, and responsible for its payment, is the only safe criterion by which to judge whether it should or should not be discounted. But the fact of a merchant or other trader offering accommodation bills for discount ought unquestionably to excite a suspicion that he is trading beyond his capital. Inquiries of the most searching description should forthwith be instituted; and unless satisfactory explanations are given, his paper should be rejected. On the same principle, the offering of bills for rediscount ought to awaken suspicions of the bankers and others who resort to so questionable a mode of carrying on business. But, except in so far as a feeling of distrust may be thus very properly excited, there does not appear to be anything in an accommodation bill *per se* to hinder it from coming within the pale of negotiability. It is a mode of obtaining a loan from a bank; and when the character of the bill is known to the banker, or is openly declared, it does not appear to be an objectionable mode.

Besides bills avowedly intended for accommodation purposes, another and a different variety of such bills is drawn by parties at a distance from each other, often men of straw, and made to appear as if they were bottomed on real transactions. Bills of this sort are, it is greatly to be regretted, always current, and often to a large extent. Of course no person of respectability can be knowingly connected with such bills, which are almost always put in motion either to bolster up some bankrupt concern, or to cheat and defraud the public. But despite the mischief of which they are productive, it appears to be pretty generally supposed that the currency of these bills is an evil which cannot be prevented. There can, however, be no real doubt that it may, at all events, be very greatly diminished; and this desirable result would be effected were it enacted that all bills shall henceforth bear upon their face what they really are; that those that are intended for accommodation purposes shall have at their head the words "*Accommodation bill;*" and that those only shall bear to be for "value received" that have grown out of *bona fide* transfers of property. An enactment of this sort could not be felt as a grievance by any one unless he had a fraudulent purpose in view. And were the impressing of a false character on a bill made a criminal offence, punishable by several years' imprisonment, there is every probability that a formidable check would be given to the issue of spurious bills, and to the manifold abuses to which the practice gives rise.

Bill-discounters who have got fictitious paper on their hands and attempt to get rid of it by concealing its character or representing it in a favourable light make themselves parties to the fraud. Such conduct is so very flagitious, that when it can be fairly brought home to the parties it should subject them to the severest penalties.

The rates of discount charged by the bank, since its establishment in 1694 down to 1845, were as follows:—

From	To		Per cent.
From Aug. 8, 1694	to Aug. 30, 1694	on Foreign bills......	6
Aug. 30, 1694	Jan. 16, 1695	Foreign bills......	$4\frac{1}{2}$

The Bank of England does not allow, either at the head

[1] Rising from 4 per cent on 3d April to 8 per cent on 20th Nov., declining again to 5 per cent. by 24th Dec., and to 3 in 1848.

[2] With the exception of one week the rate was high, varying from 4 to $5\frac{1}{2}$ from Sept. 1853 to May 1856, from which date it rose to an average of 6 per cent. until Oct. 1857, when it rapidly mounted to 10 per cent. in Dec. 1857, and thence declined to 4 in Feb. 1858.

[3] 7 was the average rate in the spring, and 6 the average in the summer of 1861.

[4] At the end of 1863 the rate rose to 7 and 8 per cent., and it oscillated about these figures throughout 1864, twice falling to 6, and twice rising to 9 per cent.

[5] The average rate in 1865 was 4, but at the close of the year it rose to 6 and 7; and in 1866 it mounted until it reached 10 per cent. on the 15th August, from which it fell to $3\frac{1}{2}$ before the end of the year.

[6] The crisis in America (see Banking in the United States, p. 341) was followed by a rapid rise from 3 per cent. on the 20th August to 9 per cent. on the 5th Nov., from which the rate receded to $4\frac{1}{2}$ before the end of the year.

office in London, or at its branches, any interest on deposits, and many plausible reasons have been advanced in defence of this rule. They are well stated in the following extract from the evidence of Mr Weguelin, formerly governor of the bank, before the Committee of 1857 :—

"We," said he, "at the Bank of England, have always considered that the proper functions of a banker were to keep the spare cash of his customer, such cash as his customer required for his daily expenditure, for the sudden demands of his business, and any accidental accumulation which might happen before the customer had occasion to invest it. That is contrasted with the system pursued by the joint-stock banks. The joint-stock bank invites a large deposit by offering a certain rate of interest for the deposit; in point of fact, the joint-stock bank becomes the investor of the money instead of the customer. The customer of a joint-stock bank does not himself invest his own money, but he employs the joint-stock bank to do it, taking the guarantee of the joint-stock bank, and taking, possibly, a lower rate of interest. Now, that system, if applied to the Bank of England, would be, I think, very prejudicial to the public interests. It would, in the first place, force upon the Bank of England to invest its reserves much more closely than it does now. If it had to pay interest upon its deposits, it could only do so by investing them in some securities that would pay a higher rate of interest than that which it pays. Its deposits also are of that particular character which would render it still more inexpedient that they should be closely invested. They consist, in the first place, of Government deposits, which rise from a low rate at one period of a quarter up to five or six millions higher at another period of a quarter, and again collapse to a very low rate at another period. Again, the private deposits consist, to a certain extent, of the deposits of the bankers and the joint-stock banks of London. Those deposits are the amounts which those bankers require to work their own business. Consequently, they are not deposits which should be very closely invested by the Bank of England. In times when there is a great accumulation of deposits in the Bank of England, it is because the public are not able at those times to find investments to their mind to employ those deposits; and consequently, it is not at all likely that the Bank of England, if that is the case with the public generally, will be able to find investments which the public themselves have not been able to do. All these reasons combined would lead me to think, that to force a system upon the Bank of England by which it should be obliged to employ its deposits very closely--much more closely than it does at present—would be not only prejudicial and unsafe as regards the Bank of England, but would be prejudicial to the public interest."—*Quest.* 159.

It is, however, obvious that this reasoning is quite inconclusive. Mr Weguelin shows clearly enough that the directors of the bank would be bound to exercise great caution in the choice and extent of their investments, but he says nothing to explain why they should not, as the managers of a joint-stock company, use every means of profitably extending their business, and it is incontestable that if the bank directors offered to receive deposits at interest, the reputation of the bank would enable them to defy the competition of the other joint-stock banks. The truth is, that the non-allowance of interest is a tradition, of no authority in itself, and operating injuriously in keeping up the delusion that the banking department of the Bank of England is an institution differing essentially in the character of its business from other banks.

Previously to 1786 the bank received an allowance for paying the dividends, superintending the transfer of the stock, &c., of the national debt, at the rate of £562, 10s. a million on its amount. In 1786 this allowance was reduced to £450 a million, the bank being, at the same time, entitled to a considerable allowance for its trouble in receiving contributions on loans, lotteries, &c. This, though long regarded as a very improvident arrangement on the part of the public, was acquiesced in till 1808, when the allowance on account of management was reduced to £340 per million on £600,000,000 of the public debt, and to £300 per million on all that it exceeded that sum, exclusive of some separate allowances for annuities, &c. The impression, however, was still entertained that the allowances for management should be further reduced, and this has been effected in the interim.

Exclusive of its functions as public banker and manager of the public debt, the Bank of England is connected with Government through the circulation. We have seen that it is entitled to issue the sum of £15,000,000 upon securities, that is, on the credit of the funds lent to Government. But for these the bank receives about 3 per cent. interest, and such being the case, the public is clearly entitled to a portion, if not to the whole amount of the profits realised by the bank on the issue of these £15,000,000. It is difficult to say how much this ought to be. The issue department of the bank seldom reissues notes, but for the most part destroys them as soon as they are returned to it. This practice is said to be necessary to enable the bank to obviate fraud, by keeping a proper account of the numbers of the notes afloat. An opinion is, however, pretty generally entertained that this might be effected by a less expensive process than that which is resorted to. And certainly, it seems to be a very wasteful proceeding, that a quantity of newly manufactured notes issued by the bank in the forenoon, and returned to her in the afternoon, should not be re-issued, but consigned to the flames. The Scotch banks are justly censurable for keeping their notes too long afloat, but this is running with a vengeance into the opposite extreme.

In 1861 a fresh arrangement was made between the Government and the bank, to endure for 25 years. Under this agreement the bank receives £300 per million on £600,000,000, and £150 per million on the amount of debt above that sum; but from these allowances are deducted £60,000 for exemption from stamp duties and the whole allowance out of profit of issue, making together nearly £200,000.

It should be observed that the responsibility and expense incurred by the bank, in managing the public debt, are very great. The temptation to the commission of fraud, in transferring stock from one individual to another, and in the payment of the dividends, is well known; and notwithstanding the skilfully devised system of checks adopted by the bank for preventing this, it has frequently sustained very great losses by forgery and otherwise. In 1803 the bank lost, through a fraud committed by one of the principal cashiers, Mr Astlett, no less than £340,000; and the forgeries of Fauntleroy, the banker, cost it a still larger sum. At an average of the ten years ending with 1831, the bank lost, through forgeries on the public funds, £40,204 a year.—(*Report on Bank Charter*, *Appen.* p. 165.)

Besides the transactions alluded to, the bank entered, on the 20th of March 1823, into an engagement with Government with respect to the public pensions and annuities, or, as they have been more commonly termed, the *dead weight*. At the end of the war, the naval and military pensions, superannuated allowances, &c., amounted to above £5,000,000 a year. They would, of course, have been gradually lessened, and ultimately extinguished, by the death of the parties; but it was resolved in 1822 to attempt to spread the burden equally over the whole period of *forty-five* years, during which it was calculated the annuities would continue to decrease. To effect this purpose, it was supposed that, upon Government offering to pay £2,800,000 a year for forty-five years, capitalists would be found who would undertake to pay the entire annuities, according to a graduated scale previously determined upon, making the first year a payment of £4,900,000, and gradually decreasing the payments until the forty-fifth and last year, when they were to amount to only £300,000. This supposition was not, however, realized. No capitalists were found willing to enter into such distant engagements. But in 1823, the bank agreed, on condition of receiving an annuity of £585,740 for *forty-four* years, commencing on the 5th of April 1823, to pay, on account of the pensions, &c., at different specified periods, between the years 1823

and 1828, both inclusive, the sum of £13,089,419.—(4 Geo. IV. c. 22.) This annuity has, in due course of time, expired.

Formerly the business transacted at the bank was so much encumbered with forms and conditions, that the generality of merchants and ordinary people rarely thought of employing it to keep their money or make their payments. But in this respect an entire change has been effected. Cheques, the minimum amount of which was formerly £10, may now be drawn of any amount, great or small; and all sorts of banking business is conducted with facility and despatch, and, it may be added, with perfect security.

The bank opens banking accounts, or, as they are called, "drawing accounts," for the safe custody, and the receipt and payment of cash, not only with merchants and traders, but with all persons who choose to keep their money at a banker's and to draw cheques against it. The bank also takes charge of its customers' bills of exchange, Exchequer bills, and other securities, and does all that is needful either in the collection of bills of exchange, the exchange of Exchequer bills, the receipt of dividends, and so forth, free of any charge. Plate-chests, and deed and security boxes, may be deposited free of expense, by customers, for safe custody. The bank looks to the average balance of cash on each account to compensate for the trouble and expense of keeping it, and in this respect the requirements of the bank are certainly not greater than those of ordinary bankers. No particular sum is required to be lodged on opening an account; it is only necessary that the party should be known as respectable, and in a condition to require a banking account. But the bank receives and holds sums of money for safe custody for parties who have no current accounts.

The following are the regulations under which accounts are conducted:—

1. All letters should be addressed to the chief cashier.
2. It is desirable that drafts should be drawn upon cheques furnished by the bank.
3. Cheques upon city bankers, eastward of King Street, Cheapside,—

Paid in by 12 o'clock may be drawn for after 1.
Do. 2 o'clock ,, ,, after 3.

4. Cheques paid in after 2, and before 3 o'clock, and cheques upon all other London bankers paid in before 12 o'clock, may be drawn for on the following morning.
5. Cheques paid in after 3 o'clock are sent out at 9 the following morning, and may be drawn for as soon as received.
6. Dividend warrants are received at the drawing office until 4 o'clock in the afternoon for all persons having accounts at the bank.
7. It is requested that notice be given at the drawing office of bills accepted payable at the bank, with the date of their maturity.
8. Persons keeping a drawing account with the bank (although not having a discount account) may tender bills for discount through the drawing office. Application for discounts or for advances on stock, Exchequer bills, &c., must be made before 2 o'clock.
9. Bills of exchange and notes not paid when due, will be noted.
10. The bank will make purchases or sales of British or foreign securities upon an order in writing addressed to the chief cashier; and dividends on stock may be received under powers of attorney granted to the cashiers of the bank.
11. Exchequer bills, bonds, railway debentures, or any other securities may be deposited, and the interest, when payable, will be received and placed to account.
12. Credits paid in to account are received without the bank-book, and are afterwards entered therein without the party claiming them.
13. Notes of country bankers, payable in London, are sent out the same day for payment if paid in before 3 o'clock.
14. The pass-books should be left at the drawing office, at least once a month, to be written up.
15. Where post-bills are required, or a payment is to be made to any office of the bank by cheque on the Bank of England, the cheque must be presented at the office upon which it is drawn, and exchanged for an order on the post-bill office, or on the office at which the payment is to be made.
16. Cash-boxes taken in, contents unknown, for such parties as keep accounts at the bank.
17. A person having a drawing account may have a discount account; but no person can have the latter without at the same time having the former. When a discount account is opened, the signatures of the parties are entered in a book kept for that purpose, and powers of attorney are granted empowering the persons named in them to act for their principals. Bills of exchange having more than 95 days to run are not eligible for discount.

N.B.—All changes in the residence of persons keeping cash at the bank are requested to be made known at the drawing office; and it is particularly requested that no gratuities be offered to the clerks of the banking offices, such gratuities being strictly forbidden.

Scotch Banks.

The Act of 1708, preventing more than six individuals from entering into a partnership for carrying on the business of banking, did not extend to Scotland. In consequence of this exemption, several banking companies, with numerous bodies of partners, have existed, for a lengthened period, in that part of the empire.

The Bank of Scotland was projected by Mr John Holland, merchant, of London, and was established by Act of the Scotch Parliament (Will. III., Parl. 1, § 5) in 1695, by the name of the Governor and Company of the Bank of Scotland. Its original capital was £1,200,000 Scotch, or £100,000 sterling, distributed in shares of £1000 Scotch, or £83, 6s. 8d. sterling, each. The Act exempted the capital of the bank from all public burdens, and gave it the exclusive privilege of banking in Scotland for twenty-one years. The objects for which the bank was instituted, and its mode of management, were intended to be, and have been, in most respects, similar to those of the Bank of England. The responsibility of the shareholders is limited to the amount of their shares. The capital of the bank was increased to £200,000 in 1774, and was enlarged by subsequent Acts of Parliament, the last of which (44 Geo. III. c. 23) was passed in 1804, to £1,500,000, its present amount.[1] Of this sum £1,000,000 has been paid up. The last-mentioned Act directed that all sums relating to the affairs of the bank should henceforth be rated in sterling money; that the former mode of dividing bank stock by shares should be discontinued; and that, for the future, it should be transferable in sums or parcels of any amount. On the union of the two kingdoms in 1707, the Bank of Scotland undertook the recoinage, and effected the exchange of the currency in Scotland. It was also the organ of Government in the issue of the new silver coinage in 1817.

The Bank of Scotland is the only Scotch bank constituted by Act of Parliament. It began to establish branches in 1696, and issued notes for one pound as early as 1704. The bank also began, at a very early period, to receive deposits on interest, and to grant credit on cash accounts, a minute of the directors with respect to the mode of keeping the latter being dated as far back as 1729. It is, therefore, entitled to the credit of having introduced and set on foot the distinctive principles of the Scotch banking system, which, whatever may be its defects, is perhaps superior to most other systems hitherto established. Generally speaking, the Bank of Scotland has been cautiously and skilfully conducted; and there can be no doubt that it has been productive, both directly and as an example to other banking establishments, of much public utility and advantage.

It may be worth mentioning, that the Act of Will. III. establishing the Bank of Scotland, declared that all foreigners who became partners in the bank should by doing so become, to all intents and purposes, naturalised Scotchmen. After being for a long time forgotten, this

[1] Although the capital of the Bank of Scotland remains, as stated in the text, a power, as yet unused, was conferred on the bank by a private Act passed in 1873 to raise its capital to £3,000,000.

clause was taken advantage of in 1818, when several aliens acquired property in the bank in order to secure the benefit of naturalization. But after being suspended, the privilege was finally cancelled in 1822.

We subjoin an *official* abstract of the constitution and objects of the Bank of Scotland, printed in 1857 for the use of the proprietors;—the terms and model of transacting business are, of course, sometimes altered, according to circumstances:—

1. The Bank of Scotland is a public national establishment, erected and regulated by the Legislature alone, and expressly as a public bank in this kingdom,—for the benefit of the nation, and for the advancement of agriculture, commerce, and manufactures, and for other objects of public policy.—(Will. Parl. 1, § 5; 14 Geo. III. c. 32; 24 Geo. III. c. 8; 32 Geo. III. c. 25; 34 Geo. III. c. 19; 44 Geo. III. c. 23.)

2. The statutory capital is at present £1,500,000 sterling. It is raised by voluntary subscription, and has been subscribed for. £1,000,000 has been called for, and paid in.—(44 Geo. III. c. 23.)

3. Subscribers, if not under obligations to the bank, may, at pleasure, transfer their right. If under obligation to the bank, the obligation must be previously liquidated; or the proceeds of the sale, at a price to the satisfaction of the directors, must be applied towards such liquidation. Transfers are made by a short assignment and acceptance thereof, both in a register appointed for that purpose. The expense, besides the Government stamp, is 11s.—(Will. Parl. 1, § 5.)

4. Bank of Scotland stock may be acquired, in any portions, by any person, community, or other lawful party whatsoever, without selection, exclusion, or limitation of numbers.—(Will. Parl. 1, § 5; 44 Geo. III. c. 23.)

5. Bank of Scotland stock may be conveyed by will, and, if specially mentioned, without expense of confirmation. It cannot be arrested; the holder's right may be adjudged. Dividends may be arrested.—(Will. Parl. 1, § 5.)

6. The Bank of Scotland is a public corporation by Act of Parliament. The bank's transactions are distinct from those of the stockholders; and theirs from those of the bank.—(Will. Parl. 1, § 5.)

7. The establishment is expressly debarred from any other business than that of banking.—(Will. Parl. 1, § 5.)

8. The management is vested, by statute, in a governor, deputy-governor, twelve ordinary, and twelve extraordinary directors. They are chosen annually, on the last Tuesday of March, by the stockholders having £250 of stock or upwards. Those above £250 have a vote for every £250, to £5000, or 20 votes. No person can have more than 20 votes. The governor must hold, at least, £2000 of stock; the deputy-governor £1500; and each director £750 [now £1000]. They swear to be equal to all persons, and cannot hold any inferior office in the bank.—(Will. Parl. 1, § 5; 14 Geo. III. c. 32; 44 Geo. III. c. 23.)

9. The executive part is conducted by a treasurer, secretary, and other public officers, all sworn. All the officers of the Bank of Scotland find due security.—(Will. Parl. 1, § 5.)

10. The board of directors sits, for the general administration of the bank, at the bank's public head office in Edinburgh. The local business of that district is also conducted at that office. For the local business in the other parts of the kingdom, the bank has its regular public offices in the principal towns. At each of these offices there is the bank agent or cashier, who gives due security, and conducts the bank's business for that district in the manner after-mentioned.—(Will. Parl. 1, § 5.)

11. The bank takes in money at all its public offices, on deposit receipts or on current deposit accounts. At the head office drafts on the branches, and at the branches drafts on the other branches and on the head office, are granted. Both at the head office and branches drafts are granted on the London, Dublin, and English and Irish provincial correspondents of the bank. All receipts and drafts are on the bank's engraved forms, and bear to be granted "For the Bank of Scotland," or "for the Governor and Company of the Bank of Scotland." At the head office official documents are signed by the treasurer, and at the branches by the agents, and all are countersigned.

Remittances can be made to the principal colonial and continental towns; and bills, payable in the colonies, and in foreign countries, can be negotiated through the bank.—(*Resolution of Court*, 1793, *as since modified.*)

N.B.—The bank has always allowed interest on deposits, at a rate varying according to circumstances.

12. Bills on London, Edinburgh, or any town in the United Kingdom, are discounted at all the bank's public offices. The bank's agents judge, in ordinary cases, of the bills presented, so that parties meet with no delay. The bank does not re-issue the bills which it has discounted.—(*Resolution of Court*, 23d Feb. 1789, *and subsequent modifications.*)

13. Government stock and other public funds may be purchased or sold, and dividends thereon may be received through the bank.

14. The bank gives credit on cash accounts at any of its offices, on bond, with security. The security may be personal co-obligants, or such other security as may be specially agreed on. Applications for cash accounts are given in to the office where the cash account is wanted, and must specify the credit desired, and the security proposed; and the individual partners, where co-partneries are proposed. Cash accounts are granted by the directors only, and are not recalled unless by their special authority. It is understood that these credits are not used as dead loans, to produce interest only. In the fair course of business, the advantage of the bank is consulted by an active circulation of its notes, and by frequent repayments to it in a way least affecting that circulation.—(*Resolution of Court*, 6th Nov. 1729, and 23d Feb. 1789.)

15. The bank's dividend has been for some time 8 [it has risen till it is now (1875) 14] per cent. per annum on its paid-up capital of £1,000,000 sterling. The dividends are paid regularly twice a year, without expense. They may be drawn either at the bank's head office, or at any of its other offices, as most agreeable to the stockholder.[1]

The above may suffice as a general outline of the mode in which the business of banking is conducted in Scotland.

The *Royal Bank of Scotland* was established in 1727. Its original capital of £151,000 has been increased to £2,000,000.

The *British Linen Company* was incorporated in 1746, for the purpose, as its name implies, of undertaking the manufacture of linen. But the views in which it originated were speedily abandoned, and it became a banking company only. Its capital amounts to £1,000,000.

None of the other banking companies established in Scotland are chartered associations with limited responsibility, the partners being liable, to the whole extent of their fortunes, for the debts of the firms. The number of partners is in every case considerable. The affairs of the banks are uniformly conducted by a board of directors, annually chosen by the shareholders.

The Bank of Scotland began, as already stated, to issue £1 notes so early as 1704, and their issue has since been continued without interruption. "In Scotland," to use the statement given in the Report of the Committee of the House of Commons of 1826 on the Promissory Notes of Scotland and Ireland, "the issue of promissory notes payable to the bearer on demand, for a sum of not less than 20s., has been at all times permitted by law; nor has any Act been passed limiting the period for which such issue shall continue legal in that country."

All the Scotch banks receive deposits of as low a value as £10, and often lower, and allow interest upon them.

The interest allowed by the banks upon deposits varies, from time to time, according to the variations in the current rate of interest. The aggregate amount of the sums deposited with the Scotch banks in 1874–5 is stated to be £78,401,070.

A witness, connected for many years with different banks in Scotland, and who had experience of their concerns at Stirling, Edinburgh, Perth, Aberdeen, and Glasgow, being examined by the Commons' Committee of 1826, stated that more than half the deposits in the banks with which he had been connected were in sums from £10 to £200. Being asked what class of the community it is that makes the small deposits, he gave the following answer,—from which it appears that the mode of conducting this branch of the bank business in Scotland has long given to that country most part of the benefits derivable from the establishment of savings-banks:—

[1] Now that fundholders may have their dividend warrants sent them by post on notifying a desire to that effect, it is strange that stockholders in the Scottish banks should be still compelled to make personal application at an office of the bank for their dividends.

"*Question.*—What class of the community is it that makes the smallest deposits?

"*Answer.*—They are generally the labouring classes in towns like Glasgow; in country places like Perth and Aberdeen, it is from servants and fishermen, and that class of the community who save small sums from their earnings, till they come to be a bank deposit. There is now a facility for their placing money in the Provident Banks, which receive money till the deposit amounts to £10. When it comes to £10 it is equal to the minimum of a bank deposit. The system of banking in Scotland is an extension of the Provident Bank system. Half-yearly or yearly those depositors come to the bank, and add the savings of their labour, with the interest that has accrued upon the deposits from the previous half-year or year, to the principal; and in this way it goes on, without being at all reduced, accumulating (at compound interest) till the depositor is able either to buy or build a house, when it comes to be £100, or £200, or £300, or till he is able to commence business as a master in the line in which he has hitherto been a servant. A great part of the depositors of the bank are of that description, and a great part of the most thriving of our farmers and manufacturers have arisen from such beginnings."

The following Table exhibits an account of the different Scotch Banks, their Partners, Branches, Authorized Circulation, Actual Circulation, Coin, &c., in 1874–5 (from Oliver & Boyd's Almanac and Banks of Issue Report).

Instituted.	Name.	Partners.	Br.	Paid up Capital.	Rest or Reserve Fund.	Dividend per cent.	Amount of Deposits.	Price per £100 Stock (per share of those marked *). 1872.	1873.	1874.
				£	£		£	£	£	£
1695	Bank of Scotland	1409	86	1,000,000	385,000	13½	10,632,000	287	292	303

* The capital of banks marked with an asterisk is in shares:—The Aberdeen Town and County Bank, £7 paid; North of Scotland Bank, £4 paid; Caledonian Bank, £2, 10s. paid.

† Dividend and bonus.

The loans or advances made by the Scotch banks are either in the shape of discounts, or upon cash-credits, or, as they are more commonly termed, *cash accounts*.

A cash-credit is a credit given to an individual by a banking company for a limited sum, seldom under £100 or £200, upon his own security, and that of two or three individuals approved by the bank, who become sureties for its payment. The individual who has obtained such a credit is enabled to draw the whole sum, or any part of it, when he pleases, replacing it, or portions of it, according as he finds it convenient, interest being charged upon such part only as he draws out. "If a man borrows £5000 from a private hand, besides that it is not always to be found when required, he pays interest for it whether he be using it or not. His bank credit costs him nothing, except during the moment it is of service to him, and this circumstance is of equal advantage as if he had borrowed money at a much lower rate of interest" (Hume's *Essay on Balance of Trade*). This, then, is plainly one of the most commodious forms in which advances can be made. Cash-credits are not, however, intended to be *dead loans;* and they are not granted except to persons in business, or to those who are frequently drawing out and paying in money.

The system of cash-credits has been very well described in the Report of the Lords' Committee of 1826 on Scotch and Irish Banking. "There is also," say their lordships, "one part of their system which is stated by all the witnesses (and, in the opinion of the Committee, very justly stated) to have had the best effects upon the people of Scotland, and particularly upon the middling and poorer classes of society, in producing and encouraging habits of frugality and industry. The practice referred to is that of cash-credits. Any person who applies to a bank for a cash-credit is called upon to produce two or more competent sureties, who are jointly bound; and after a full inquiry into the character of the applicant, the nature of his business, and the sufficiency of his securities, he is allowed to open a credit, and to draw upon the bank for the whole of its amount, or for such part as his daily transactions may require. To the credit of the account he pays in such sums as he may not have occasion to use, and interest is charged or credited upon the daily balance, as the case may be. From the facility which these cash-credits give to all the small transactions of the country, and from the opportunities which they afford to persons who begin business with little or no capital but their character to employ profitably the minutest products of their industry, it cannot be doubted that the most important advantages are derived to the whole community. The advantage to the banks that give these cash-credits arises from the call which they continually produce for the issue of their paper,[1] and from the opportunity which they afford for the profitable employment of part of their deposits. The banks are indeed so sensible that, in order to make this part of their business advantageous and secure, it is necessary that their cash-credits should (as they express it) be frequently operated upon, that they refuse to continue them unless this implied condition be fulfilled. The total amount of their cash-credits is stated by one witness to be £5,000,000, of which the average amount advanced by the banks may be one-third."

The expense of a bond for a cash-credit of £500 is 12s. 6d. stamp duty, and a charge of from 5s. to 10s. 6d. per cent. for preparing it.

There have been, on the whole, comparatively few failures among the Scotch banks. In 1793 and 1825, when so many of the English banks were swept off, there was not a single establishment in Scotland that gave way. This superior solidity appears to have been owing to various causes,—partly to the banks having, for the most part, large bodies of partners, who, being conjointly and individually bound for the debts of the companies to which they belong, go far to render their ultimate security all but unquestionable, and partly to the facility afforded by the law of Scotland of attaching a debtor's property, whether it consist of land or movables, and making it available for the payment of his debts. This last-mentioned circumstance was referred to as follows, in the Report already alluded to:—

[1] The advantage of an increased issue is, however, much reduced, when the authorized issues are exceeded, and cash reserves are kept in hand equal to the excess.

"A creditor in Scotland is empowered to attach the real and heritable as well as the personal estate of his debtor, for payment of personal debts, among which may be classed debts due by bills and promissory notes; and recourse may be had, for the purpose of procuring payment, to each description of property at the same time. Execution is not confined to the real property of a debtor merely during his life, but proceeds with equal effect upon that property after his decease.

"The law relating to the establishment of records gives ready means of procuring information with respect to the real and heritable estate of which any person in Scotland may be possessed. No purchase of an estate in that country is secure until the sasine (that is, the instrument certifying that actual delivery has been given) is put on record, nor is any mortgage effectual until the deed is in like manner recorded.

"In the case of conflicting pecuniary claims upon real property, the preference is not regulated by the date of the transaction, but *by the date of its record*. These records are accessible to all persons; and thus the public can with ease ascertain the effective means which a banking company possesses of discharging its obligations; and the partners in that company are enabled to determine, with tolerable accuracy, the degree of risk and responsibility to which the private property of each is exposed."

But, on the whole, we are inclined to think that the long familiarity of the inhabitants with banks and paper money, and the less risk that has attended the business of banking in Scotland, have been the principal causes of the greater stability of the Scotch banks. This stability was not, however, everywhere exhibited in the crisis of 1857, when two of the principal Scotch banks, the headquarters of which were in Glasgow, were compelled to stop payments. They had very large capitals, the Western Bank £1,500,000, and the City of Glasgow Bank £1,000,000, with a great many branches, large amounts of deposits, and very numerous and wealthy proprietary bodies. Had the management of the Western Bank displayed anything like ordinary skill and prudence, it might have gone triumphantly through a far more serious trial. But having advanced immense sums to a few firms that never were entitled to any considerable credit, it was so crippled that, for a lengthened period before its stoppage, it was reduced to the expedient of sending up the bills it had discounted in Glasgow to be rediscounted in London; and when this resource failed it, and the other banks declined to come forward to its assistance, nothing remained for it but to shut its doors.[1] On the affairs of the bank being investigated by a committee appointed for the purpose, it was found that they were in a much worse state than any one could have anticipated. The losses exceeded two millions, and were directly attributable to the carelessness and negligence of directors, and the incompetence of the managers appointed by them.

We have already explained the nature of Sir Robert Peel's Act of 1845 (following that of 1844) dealing with Scotch banks. It allowed the Scotch banks then exercising the privilege of issuing notes to continue to exercise it, without limitation of amount, but subject to the condition, that for every note issued by a bank above its average circulation the year preceding the 1st May 1845 an equal amount in coin should be kept in its coffers. No bank established after the passing of the Act was allowed to issue notes. No change was effected by the Act in the denomination of notes issued, which remained, therefore, of £1 and upwards. Many theorists have urged that £1 notes should be forbidden in Scotland, just as others have argued in favour of their being again put into circulation in England. This question cannot be settled upon abstract arguments. We have no doubt that the balance of reasoning is in favour of the issue of £1 notes, provided they are issued under regulations securing their convertibility at all times and under all circumstances, but these regulations are wanting in Scotland. Legislation on the subject should not take the form of suppressing £1 notes entirely, but of withdrawing the privilege of issuing them from the existing banks, and vesting it in a public institution governed by fixed rules analogous to those of the issue department of the Bank of England. When the convertibility of notes is thus made certain, the single valid objection against the issue of those of £1 denomination disappears. It may be added that more than one-half the total issues of the banks established in the Australian colonies consists of £1 notes.

A complaint has been often raised that the Act of 1845 gave the existing Scotch banks a practical monopoly of the business of banking in North Britain, and it must be admitted to be the fact, that only one new bank has been established in Scotland since the passing of the Act, and that bank carried on business for a short time only. It is, however, true that legislation precisely the same has not prevented the establishment of new banks in Ireland, and it is doubtful whether the observed fact is rightly attributed to the cause assigned to it. With the exception of London, and some of the larger provincial towns, there have been very few banks established in England since 1836, eight years before the Bank Charter Act; and of the banks established in 1835 and 1836, very many were formed by the conversion of pre-existing private banks into joint-stock associations. The truth appears to be that the natural obstacles to the establishment of a new bank in a district already occupied by banks and bankers are almost insuperable. A bank cannot be successful unless it commands credit; and those who want a place of safe keeping for their money select establishments that have been tried and tested through long years. Hence it happens that, though private banks of long standing continue in esteem, the attempts to set up new private banks are most rare; and, unless the wealth and prosperity of a neighbourhood have rapidly developed, so that capitalists have risen to prominence in it who are not connected as shareholders or directors with existing banks, it is not easy to form joint-stock associations of weight enough to compete with the institutions in possession of the field. It is not necessary to refer the absence of new banking companies in Scotland or elsewhere to the legislation of Sir Robert Peel. Though he allowed the Scotch banks to increase indefinitely the issue of their notes, it was upon condition of keeping in hand cash to represent every note above fixed limits; so that the amount of profit derivable from their issues is not capable of increase, and the value of their privileges will have been strictly included in the selling price of shares in these banks since 1845. As far as the privilege of issue goes, capitalists preparing to start a new banking association in Scotland would be in the same position as in buying shares in an established company; and if they do not start an association of their own, it is from the difficulty of attracting confidence, rather than because they would not enjoy the profits of a privileged circulation for which they would have to pay a full value. It must also be observed that the competition among the existing banks is sufficiently active to have caused them to increase the number of their branches 40 per cent. since 1845.

Another question has been raised in relation to Scotch banks, which was the subject of a keen parliamentary discussion during the past session (1875). It has been mentioned (*ante*, p. 322) that English joint-stock banks of issue are debarred from setting up branches in London, or within sixty-five miles of it, a prohibition originally imposed on them in the interest of the Bank of England as a bank of issue. There is no such prohibition affecting Scotch and Irish banks, which can set up offices in London or elsewhere in England subject to the single condition affecting all banking

[1] The management of the City of Glasgow Bank was, as compared with that of the Western Bank, prudent and skilful. It recommenced and continues business.

establishments set up in England since 1844, that notes other than Bank of England notes are not issued at such offices; and it is obvious that a Scotch or Irish banking company establishing a head office in London would be able to give it at once a large agency business, and would be able to feed it continuously with new connections owing to the flow of immigration from Scotland and Ireland to London. Accordingly, the directors of the National Bank of Ireland began to conduct the general business of banking at their head office in London in 1854, and they have subsequently set up seven or eight branches in the metropolis, each of which is understood to be the centre of much business. This example was so far followed, that the National Bank of Scotland started an office in London in 1864; the Bank of Scotland did the same in 1867; and the Royal Bank in 1874, having obtained a private Act for the purpose. The Clydesdale Bank also opened three branches in Cumberland in 1874. In consequence of this action Mr Goschen brought into Parliament a bill, the object of which was to disable Scotch banks from coming into England, as English joint-stock banks of issue are disabled from coming to London. The bill did not extend to Irish banks, as they were held too firmly settled in the metropolis to be expelled from it. Two arguments were advanced in favour of this measure: the first, that it was hard that Scotch banks should be permitted to do that which is denied to English joint-stock banks; but it is an easy, and, as it would seem, a conclusive answer to this argument, that English joint-stock banks of issue should be freed from the disability now imposed upon them. Now that an increase in its issue is not a measure of profit to the Bank of England, there is no reason why these country banks of England should not be allowed to set up head offices in London, subject to the law forbidding the issue of their notes in London. The second argument in favour of Mr Goschen's measure was, that something ought to be done to hasten that unification of issues which Sir Robert Peel contemplated; and if the Scotch banks had come to Parliament asking for a liberty they did not possess, there would have been some plausibility in this argument. It is to be feared that the whole strength of the support to Mr Goschen's bill sprang from the jealousy of the existing bankers of London of any intrusion into their domain. Unworthy as this source of opposition was, it prevailed so far as to cause the appointment of a Select Committee of the House of Commons to consider the law and practice of banking, and this Committee's report has just appeared as these sheets are passing through the press (August 1875).

Banking in Ireland.

"In no country, perhaps," says Sir Henry Parnell, "has the issuing of paper money been carried to such an injurious excess as in Ireland. A national bank was established in 1783, with similar privileges to those of the Bank of England in respect to the restriction of more than six partners in a bank, and the injury that Ireland has sustained from the repeated failure of banks may be mainly attributed to this defective regulation. Had the trade of banking been left as free in Ireland as in Scotland, the want of paper money that would have arisen with the progress of trade would in all probability have been supplied by joint-stock companies, supported with large capitals and governed by wise and effectual rules.

"In 1797, when the Bank of England suspended its payments, the same privilege was extended to Ireland; and after this period the issues of the Bank of Ireland were rapidly increased. In 1797 the amount of the notes of the Bank of Ireland in circulation was £621,917; in 1810, £2,266,471; and in 1814, £2,986,999.

"These increased issues led to corresponding increased issues by the private banks, of which the number was fifty in 1804. The consequence of this increase of paper was its great depreciation; the price of bullion and guineas arose to 10 per cent. above the mint price; and the exchange with London became as high as 18 per cent., the par being 8⅓. This unfavourable exchange was afterwards corrected, not by any reduction in the issues of the Bank of Ireland, but by the depreciation of the British currency in the year 1810, when the exchange between London and Dublin settled again at about par.

"The loss that Ireland has sustained by the failure of banks may be described in a few words. It appears, by the Report of the Committee on Irish Exchanges in 1804, that there were, at that time, in Ireland fifty registered banks. Since that year a great many more have been established, but the whole have failed, one after the other, involving the country from time to time in immense distress, with the following exceptions—First, a few that withdrew from business; secondly, four banks in Dublin; thirdly, three at Belfast; and, lastly, one at Mallow. These eight banks, with the new Provincial Bank and the Bank of Ireland, are the only banks now (1827) existing in Ireland.

"In 1821, in consequence of eleven banks having failed nearly at the same time, in the preceding year, in the south of Ireland, Government succeeded in making an arrangement with the Bank of Ireland, by which joint-stock companies were allowed to be established at a distance of fifty miles (Irish) from Dublin, and the bank was permitted to increase its capital from 2½ to 3 millions sterling. The Act 1 and 2 Geo. IV. c. 72, was founded on this agreement. But ministers having omitted to repeal in this Act various restrictions on the trade of banking that had been imposed by 33 Geo. II. c. 14, no new company was formed. In 1824 a party of merchants of Belfast, wishing to establish a joint-stock company, petitioned Parliament for the repeal of this Act of Geo. II.; and an Act was accordingly passed in that session, repealing some of its most objectionable restrictions (5 Geo. IV. c. 73).

"In consequence of this Act, the Northern Bank of Belfast was converted into a joint-stock company, with a (nominal) capital of £500,000, and commenced business on the 1st of January 1825. But the restrictions of 33 Geo. II., and certain provisions contained in the Acts 1 and 2 Geo. III., and 5 Geo. IV., obstructed its progress, and they found it necessary to apply to Government to remove them; and a bill was accordingly introduced, which would have repealed all the obnoxious clauses of the 33 Geo. II., had it not been so altered in the committee as to leave several of them in force. In 1825 the Provincial Bank of Ireland commenced business with a (nominal) capital of £2,000,000; and the Bank of Ireland has of late established branches in all the principal towns."[1]

Since Sir Henry Parnell published the pamphlet from which we have taken the foregoing extract, several joint-stock banking companies have been founded in Ireland. The Provincial Bank, to which Sir Henry alludes, has a paid up capital of £540,000, and has been well and profitably managed. But others have been less fortunate. The Agricultural and Commercial Bank of Ireland, established in 1834, with 2170 partners, a paid up capital of £352,790, and many branches, stopped payment during the pressure in November 1836, and by doing so involved many persons in great distress. It appears to have been extremely ill-managed. The auditors appointed to examine into its affairs reported—"Its book-keeping has been found to be so faulty, that we are convinced no accurate balance-sheet could at any time have been constructed."

[1] *Observations on Paper Money*, &c., by Sir Henry Parnell, p. 171.

And they significantly added—"the personal accounts at the head office require a diligent and searching revision."

The Tipperary Joint-Stock Bank, which was established in 1839, and stopped payments in 1855, appears to have been little, if at all, better than a mere swindling engine. Luckily it did not issue notes; and the sphere of its operations was not very extensive. But, so far as its influence went, nothing could be worse, being ruinous alike to the majority of its partners and to the public.

We have in the previous section on Scotch banks mentioned the fact of the establishment by the National Bank of Ireland of a head office and of several branches in London. This example has been so far followed by the Provincial Bank that it has also set up a head office in London, without, however, competing for general business in the metropolis. An addition was made to the number of Irish banks in 1864 by the establishment of the Munster Bank (Limited), having its head office in Cork. It has established upwards of 40 branches, and pays a dividend of 12 per cent. to its shareholders.

We borrow principally from Thom's *Irish Almanac*, the most valuable publication of its class, the following details with respect to the Irish banks in 1875:—

Account of Joint-Stock Banks existing in Ireland in 1875, *their Branches, Capital, Fixed Issues, &c*

Instituted.	Banks	No of Branches	Subscribed Capital.			Paid up Capital.		Latest Dividend per Annum declared	Reserve Fund and Balance after last Dividend.
			No of Shares.	Per Share.	Amount.	Per Share	Amount.

Bank of Amsterdam.

The Bank of Amsterdam was founded in 1609, on strictly commercial principles and views, and not to afford any assistance, or to intermeddle with the finances of the state. Amsterdam was then the great entrepôt of the commerce of the world, and of course the coins of all Europe passed current in it. Many of them, however, were so worn and defaced as to reduce their general average value to about 9 per cent. less than their mint value; and, in consequence, the new coins were immediately melted down and exported. The currency of the city was thus exposed to great fluctuations; and it was chiefly to remedy this inconvenience and to fix the value or par of the current money of the country, that the merchants of Amsterdam established a "bank," on the model of that of Venice. Its first capital was formed of Spanish ducats or ducatoons, a silver coin which Spain had struck in the war with Holland, and with which the tide of commerce had enriched the country it was formed to overthrow. The bank afterwards accepted the coins of all countries, worn or new, at their intrinsic value, and made its own bank-money payable in standard coin of the country, of full weight, deducting a "brassage" for the expense of coinage, and giving a credit on its books, or "bank-money," for the deposits.

The Bank of Amsterdam professed not to lend out any part of the specie entrusted to its keeping, but to retain in its coffers all that was inscribed on its books. In 1672, when Louis XIV. penetrated to Utrecht, almost every one who had an account with the bank demanded his deposit, and these were paid off so readily that no suspicion could exist as to the fidelity of the administration. Many of the coins then brought forth bore marks of the conflagration which happened at the Hôtel de Ville, soon after the establishment of the bank. This good faith was maintained till about the middle of last century, when the managers secretly lent part of their bullion to the East India Company and Government. The usual "oaths of office" were taken by a religious magistracy, or rather by the magistracy of a religious community, that all was safe; and the good people of Holland believed, as an article of their creed, that every florin which circulated as bank-money had its metallic constituent in the treasury of the bank, sealed up, and secured by oaths, honesty, and good policy. This blind confidence was dissipated in December 1790, by a declaration that the bank would retain 10 per cent. of all deposits, and would return none of a less amount than 2500 florins.

Even this was submitted to and forgiven. But, four years afterwards, on the invasion of the French, the bank was obliged to declare that it had advanced to the States of Holland and West Friesland, and the East India Company, more than 10,500,000 florins, which sum it was, of course, unable to make up to the depositors, to whom, however, it assigned its claims on the states and the company. Bank-money, which previously bore an agio of 5 per cent. immediately fell to 16 per cent. below current money.

This epoch marked the fall of an institution which had long enjoyed an unlimited credit and had rendered the greatest services. The amount of treasure in the vaults of the bank, in 1775, was estimated by Mr Hope at 33,000,000 florins.[1]

The Bank of France.

This bank, second in magnitude and importance to the Bank of England only, was originally founded in 1800, but was not placed on a solid and well-defined basis till 1806. Its capital, which was originally fixed at 45,000,000 fr., was raised in the last-mentioned year to 90,000,000 fr., divided into 90,000 shares or *actions*, of 1000 fr. each. Of these shares, 67,900 have passed into the hands of the public; the remaining 22,100, having been purchased up by the bank out of its surplus profits, were subsequently

[1] Storch, *Cours d'Economie Politique*, tom. iv. p. 102.

cancelled. Hence its capital amounted, down to 1848, to 67,900,000 fr. (£2,716,000), with a reserve fund, first of 10,000,000 fr., and more recently of 12,980,750 fr. Since 1806 the bank has enjoyed the privilege of being the only institution in Paris entitled to issue notes payable on demand; and, as will be afterwards seen, it is now the only authorized issuer of such paper in France. Its charter and exclusive privileges have been prolonged and varied by laws passed at different periods.

The bank has established, at different periods since 1817, offices or branches (*succursales*) in different parts of the country. They are managed nearly in the same way as the parent establishment; but their operations were long on a comparatively small scale. These are exclusive of the departmental banks united, as will be immediately seen, to the bank in 1848.

Notwithstanding the skill and caution with which its affairs have generally been conducted, the revolution of 1848 brought the bank into a situation of extreme danger. It had to make large advances to the Provisional Government and the city of Paris. And these circumstances, combined with the distrust that was universally prevalent, occasioned so severe a drain upon the bank for gold, that to prevent the total exhaustion of its coffers, it was authorized, by a decree of the 16th March 1848, to suspend cash payments, its notes being at the same time made legal tender. But to prevent the abuse that might otherwise have taken place under the suspension, the maximum amount of its issues was fixed at 350 millions. The bank was then also authorized to reduce the value of its notes from 500 fr. to 200 and 100 fr.

Previously to 1848, joint-stock banks, on the model of that of Paris, and issuing notes, had been established in Lyons, Marseilles, Bordeaux, Rouen, and other large cities. And it was then determined that these banks should be incorporated with the Bank of France, and made branches of the latter. This was effected by decrees issued on the 27th April and 2d May 1848, by which the shareholders of the banks referred to (nine in number) were allowed, for every 1000 fr. nominal value of their shares, a share of 1000 fr. nominal value of the stock of the Bank of France. And, in consequence of this measure, 23,351 new shares, representing a capital of 23,351,000 fr., were added to the stock of the Bank of France, making the latter consist of 91,250,000 fr. divided into 91,250 shares. In 1851 the bank resumed specie payments.

The suppression of the local issues of the departmental banks was, no doubt, a judicious measure, and was indispensable, indeed, to secure the equal value of the paper circulating in different parts of the country. This, however, might have been effected by the mere stoppage of the issues of the departmental banks, without consolidating them with the Bank of France. The latter measure is one of which the policy is very questionable; and there are, as already seen, good grounds for thinking that the banking business of the departments would have been more likely to be well conducted by local associations, than by branches of the Bank of France. Constant additions have been made to the number of branches, which now exceeds seventy.

Owing to the war with Russia, and still more to the rage for speculation, and the drain for silver to the East that followed it, the Bank of France became exposed to considerable difficulties. And in the view of strengthening its position, and also, it may be presumed, of providing a loan for Government, a law was passed (9th June 1857), by which the capital of the bank was increased from 91,250 shares of 1000 fr. each to 182,500 shares of 1000 fr. each. The new shares were assigned to the existing proprietors at the rate of 1100 fr. per share, producing a total sum of 100,375,000 fr., of which 100 millions were lent to Government at 3 per cent. Hence the measure, though it added to the credit and security of the bank, made no addition to the means directly at its disposal.

Down to the passing of this law, the bank could not raise the rate of interest on loans and discounts above 6 per cent. But this impolitic restriction was removed, and the bank authorized to charge any rate of interest which she reckoned expedient, except upon advances to Government, the maximum interest on which was limited to 3 per cent. The bank was farther authorized to issue notes of the value of 50 fr., to make advances on railway shares, &c., and the charter was extended to 1897.

The management of the Bank of France was severely tried in the latter part of 1864 by the occurrence of a financial crisis at Paris; and in January 1865 a commission of inquiry was appointed to examine into the principles and practice of banking. There was, however, nothing mysterious or exceptional in the experience of 1864. Speculation had been much stimulated in France by the establishment of companies (Crédit Foncier, Crédit Mobilier, &c., &c.) for the undertaking of public works, and much capital was locked up and more pledged towards the completion of enterprises supposed at first to be highly profitable, but in reality offering a distant and doubtful promise of remuneration. The crisis of 1864 was the dissipation of these delusions, and the voluminous publications of evidence and opinion by the commission of inquiry produced no practical consequences.

The war of 1870–71 could not but have an important influence on the operations of the bank. Successive Governments resorted to it for assistance, which was obtained by increasing the issue of its notes and by giving them a forced currency. The rate of interest, which had been 2½ per cent. from May 1867, rapidly rose to 6 and 6½, at which it remained with scarcely any variation from 9th August 1870 till late in the year 1872. The rate would probably have risen much higher, but on the 13th August a law was approved suspending the liability of the acceptors of bills current to meet them at maturity, and this suspension was renewed until it was finally withdrawn in July 1871. The amount of unpaid bills held by the bank reached a maximum of 368 millions of francs, but the ultimate loss was extremely small. On the 23d June 1870 the metallic reserve at the bank was 1318¼ millions of francs, which was reduced to a minimum of 505 millions on the 24th December of the same year. The notes in circulation before the war had been about 1400 millions of francs; but before the end of the year 1870 their volume had increased to 1700 millions; and this again rose to 2000 millions before July 1871, and to 2400 millions before the end of 1871. A law of the 29th December 1871 fixed the maximum at 2800 millions, which was finally raised on 15th July 1872 to a maximum of 3200 millions. The debt of the state to the bank increased concurrently with this increase of issues, which was, indeed, authorized for the purpose of enabling the bank to assist the treasury. On the 26th December 1870 the bank held treasury "bons" to the extent of 174,800,000 francs only, but on the 30th November 1871 it held 1,193,600,000 of these "bons," and in August 1872 the amount reached 1,363,100,000 francs. A law of the 21st June 1871, followed by an agreement between the bank and the Government, provided for the repayment of this debt in annual payments of 200 millions, but up to this time (August 1875) the income of the state has never been large enough to provide the whole of this sinking fund. The bank has, however, been able to increase its metallic reserve through the liquidation of securities and the accumulation of deposits; so that, after having been reduced,

as we have said, to 505 millions in December 1870, and not attaining to more than 634 millions in December 1871, it rose in the same month of 1872 to 793 millions, in 1873 to 820 millions, and in 1874 to 1331, or just the amount at which it stood before the declaration of war. Its volume has, however, continued to increase, and on the 25th March of this year (1875) it stood at 1528 millions; and the forced currency of the notes of the bank might be at any time withdrawn. It must be admitted that the management of the bank throughout these years of difficulty has been eminently prudent and successful.

The bank is obliged to open a *compte courant* for any one who requires it, and performs services, for those who have such accounts, similar to those performed for their customers by the banks in London. The bank does not charge any commission on current accounts, so that its only remuneration arises from the use of the money placed in its hands by the individuals whose payments it makes. It is probable, therefore, as has been alleged, that this part of the business is but little profitable. The bank also discounts bills with three signatures at variable dates, but not having more than three months or ninety days to run. Besides discounting bills, the bank makes advances on stocks and pledges of various kinds, and undertakes the care of valuable articles, such as plate, jewels, title-deeds, &c., at a charge of $\frac{1}{8}$ per cent. on the value of the deposit for every period of six months and under.

The administration of the bank is vested in a council of twenty-one members, viz., a governor and two sub-governors, nominated by the chief of the state, and fifteen directors and three censors, nominated by the shareholders. The bank has a large surplus capital or rest. In 1848 the dividends only amounted to 75 fr. per share. In 1855 and 1856 they were 200 and 272 fr. on each share. In 1870 they fell to 114 fr., but rose again to 300 fr. in 1871, and to 320 fr. in 1872. In July 1856 the 1000 fr. share of bank-stock was worth 4075 fr.; in July 1857 it had sunk to 2880 fr. It is now (1875) worth about 3850 fr.

Banking in the United States.

Before the late Civil War it had been the uniform practice of the different States of the Union to allow banks to be established for the issue of notes, payable in specie on demand. In cases where the liability of shareholders in banks was to be limited to the amount of their shares, they had, previously to 1838, to be established by Acts of the local legislatures; but, in general, these were easily obtained, and it may be said that banking was quite free, and that, practically, all individuals or associations might issue notes, provided they abided by the rules laid down for their guidance, and engaged to pay them when presented.

Under this system the changes in the amount and value of the paper currency of the United States were greater than in any other country, and it produced an unprecedented amount of bankruptcy and ruin.

Between 1811 and 1820, about 195 banks, in different parts of the Union, became bankrupt; and it is said, in a report by the Secretary of the Treasury of the United States, dated 12th May 1820, that these failures, which mostly happened in 1814 and 1819, produced a state of distress so general and severe that few examples of the like had then occurred.

But bad as this instance was, it was nothing to that which took place subsequently to 1834. The accounts of the aggregate issues of the banks differ a little; but the following statement is believed to be very nearly accurate, viz. :—

Years.	Notes.
1830	$66,628,898
1834	94,839,570
1835	103,692,495
1836	110,310,638
1837	149,185,890

Now observe, that this sudden and enormous increase took place under the obligation which we are told is quite enough to prevent all abuse of paying notes on demand. The result was what most men of sense must have anticipated, viz., that a revulsion took place, and that every bank within the Union, without, it is believed, a single exception, stopped payment in 1837.

In 1838 such of the banks as had been best managed and had the largest capitals resumed payment in specie. But in 1839 and 1840 a farther crash took place; and the bank-notes afloat, which, as has been seen, amounted to $149,185,890 in 1837, sunk to $83,734,000 in 1842, and to $58,563,000 in 1843. It is supposed that in this latter crash nearly 180 banks, including the Bank of the United States, were totally destroyed. And the loss occasioned, by the depreciation which it caused in the value of stocks of all kinds and of all sorts of property, was quite enormous. And yet, vast as that loss was, it was really trifling, as a writer in the *American Almanack* has stated, compared with "the injury resulting to society from the upheaving it occasioned of the elements of social order, and the utter demoralization of men by the irresistible temptation to speculation which it afforded, ending in swindling to retain ill-gotten riches."

The evils of the American system were aggravated by the lowness of the notes which most banks issued. This brought them into the hands of retail traders, labourers, and others in the humbler walks of life, who always suffer severely by the failure of a bank.

After 1838 and 1842 various measures were taken in nearly all the States, but principally in New York, to restrain the free action of the banks, and to prevent a repetition of the calamities referred to.

In New York, for example, banks were divided into two great classes—the incorporated and the free banks. The former, incorporated by a State law, had to conform to certain regulations, and to contribute a half per cent. annually upon their capital to a security fund, which was devoted to the payment of the notes of defaulting banks. But this was a most objectionable plan; for, in the first place, it did not prevent bankruptcies, and, in the second place, it compelled the well-managed banks to contribute to a fund which went to pay the debts of those that were mismanaged. It consequently declined in favour, and soon became rarely acted upon.

In the other or free banking system, all individuals or associations who chose to deposit securities (minimum amount, $100,000) for their payment were allowed to issue an equal amount of notes. And this was certainly by far the more efficient as well as the more popular of the two plans. It was, however, not free from objection; because, 1*st*, A longer or shorter, but always a considerable, period necessarily elapses after a bank stops before its notes can be retired; and 2*d*, The securities lodged for the notes were necessarily at all times of uncertain and fluctuating value, while, in periods of panic or general distrust, they became all but inconvertible. The Sub-Secretary of the Treasury of the United States animadverted as follows on this plan, in a letter dated 27th Nov. 1854 :—

"The policy of many of the State Governments has of late years consisted in encouraging the issue of small notes, by sanctioning the establishment of what are popularly called 'free banks,' with deposits of stocks and mortgages for the 'ultimate' security of their issues. This 'ultimate' security is, it may be admitted, better than no security at

all. The mischief is, that it is least available when most wanted. The very causes which prevent the banks from redeeming their issues promptly, cause a fall in the value of the stocks and mortgages on 'the ultimate security' of which their notes have been issued. The 'ultimate' security may avail something to the broker who buys them at a discount, and can hold them for months or years; but the labouring man who has notes of these 'State security banks' in his possession, finds, when they stop payment, that 'the ultimate security' for their redemption does not prevent his losing twenty five cents, fifty cents, or even seventy-five cents in the dollar.

"In a circulating medium we want something more than 'ultimate security.' We want also 'immediate' security; we want security that is good to-day, and will be good to-morrow, and the next day, and for ever thereafter. This security is found in gold and silver, and in these only."[1]

The Report of the Superintendent of Banking for the State of New York for 1856 showed that the securities he then held in trust amounted to $39,359,071, which were almost wholly lodged by banking associations and individual bankers.

During the year the securities held in trust for the under-mentioned banks that had become insolvent in 1855 were disposed of. But the sums realized by their sale did not in any case suffice to pay the notes at par; while a period, varying from two to four years, would have to elapse before the affairs of the insolvent banks were finally settled.

Names of Banks that failed	Notes Redeemed.	Rates of Redemption.	Expiration of Time for Redemption.
Eighth Avenue Bank. ..	All.......... ..	94 cents.	May 21, 1861
Farmers' Bank, Onondaga...	All.... ..	85 cents.	Nov. 12, 1859
James' Bank	All....	91 cents.	June 17, 1858
Merchants and Mechanics' Bank, Oswego .	All.... . ..	77 cents.	Sept. 28, 1860
New Rochelle, Bank of.	Stock notes.	Par	June 17, 1858
New Rochelle, Bank of.	Stock and estate notes	81 cents.	June 17, 1858

This statement set the defective nature of the security system, as administered in New York, in the clearest point of view. It might, no doubt, have been improved by increasing the proportion of securities to notes. But, owing to the variety of securities that were taken (viz., all manner of bonds and mortgages, state, canal, and railway stocks, &c., &c.), and the uncertainty of their value, a great deal of risk was always incurred in accepting them, and they could never form a proper foundation on which to issue notes.

In 1857 another crash took place, and *all* the banks in the Union, from the Gulf of Mexico to the frontiers of Canada, again stopped payments.

There had been a rapid increase of discounts since 1851, and that increase was especially great in 1856, and went on augmenting down to August 1857. On the 8th of that month the discounts and advances by the New York banks amounted to $122,077,252, the deposits in their possession being, at the same time, $94,436,417. This was the maximum of both. On the 24th of August the Ohio Life and Trust Company, which carried on an extensive banking business in New York, stopped payments, and by so doing gave a severe shock to credit and confidence, which the suspension of two or three more banks turned into a panic. Notes being in a certain degree secured, the run upon the banks was principally for deposits. And to meet it they so reduced their discounts and advances, that, on the 17th October, they amounted to only $97,245,826. This sudden and violent contraction necessarily occasioned the suspension of many of those mercantile houses that had depended on the banks for discounts. And it did this without stopping the drain for deposits, which had sunk, on the 17th October, to $52,894,623, being a decrease of $41,546,784 in about two months. The universal stoppage of the banks was a consequence of these proceedings.

The Civil War had as one of its consequences the introduction of a general banking law in the United States, comformable in many respects to the principles of what we have described as the free banking law of New York. At the beginning of the war in 1861, the amount of paper money in circulation was about $200,000,000, of which $150,000,000 had been issued in the loyal States; and the coin in circulation was estimated at $275,000,000. The necessities of the Treasury very soon compelled the Government to borrow from the associated banks of New York, Philadelphia, and Boston, and to issue demand-notes to the extent of $50,000,000,--which, however, were not at first made legal tender. In February 1862 an Act was passed by Congress authorizing the issue of $150,000,000, in Treasury notes of not less than $5 each, out of which, however, $50,000,000 were in lieu of the notes already issued; and this issue was declared to be legal tender except in discharge of customs' duties, and of the payment of interest by the United States on the national debt. It will be easily understood that coin went out of circulation, and a premium on gold was established, which increased as the amount of the Treasury notes was increased by successive legislation, and as national bank-notes came to be issued in pursuance of the law we must proceed to describe. This is the Banking Law of the 25th February 1863, which, as amended by the Act of the 3d June 1864, now continues in force. By this law a Currency Bureau and Comptroller of Currency were appointed in the Treasury Department, with the power to authorize banking associations of not less than five persons subscribing, except in very small towns, a minimum capital of $100,000, 50 per cent. to be paid up at once, and the remainder within six months. It was enacted that any such association, before commencing business, must transfer to the Treasurer of the United States any United States interest-bearing bonds not less than one-third of the capital stock, and should thereupon receive from the Comptroller of the Currency circulating notes of different denominations in blank, registered and countersigned, equal in amount to 90 per cent. of the current market value of the bonds so transferred, but not exceeding their par value. The whole amount of notes thus issued was not to exceed $300,000,000, one-half to be apportioned among the States according to their representative population, and the other half to be apportioned with regard to the existing banking capital, resources, and business of the States.

The banks already existing in the several States were rapidly transformed into national banks under the operation of this law, and their previous notes withdrawn in exchange for the new national bank issue. The currency of the Union thus came to consist of the demand-notes of the Treasury, which rose in 1865 to about $450,000,000, and of the notes of the national banks, which rapidly approached the limit of $300,000,000,—the latter notes passing throughout the Union, whatever the bank through which they were issued, as freely as the former, since the ultimate payment of them was secured by the deposit under the law we have stated, of an adequate amount in United States' bonds at the Treasury. It is not our purpose to trace the subsequent financial history of the States, but the experience of 1873 must be referred to for the instruction it affords. As no sufficient steps were taken after the termination of the war to reduce the swollen value of the

[1] The above statements are taken from a paper read by Lord Overstone to the Committee on Banks.

currency, gold remained out of circulation, though with the growth of business the premium on it declined to an average rate of 12 per cent.; but no inconvenience was felt from the existence of a pure paper circulation, and the opinion, in fact, arose that the currency thus established was a sure preventive of recurrent panics and exaggerated rates of discount. But in September 1873 the financial house of Jay, Cooke, & Co., having locked up a large amount of capital in railway enterprises not immediately if ever likely to be productive, suspended payments; other financial houses were forced to take the same step, several banks closed their doors, and a severe panic set in. The holders of the notes in circulation of the banks that failed were protected by the deposit of bonds at the Treasury, and the notes were never discredited; but the financial distress throughout the Union was excessive, and continued for many months. It was practically demonstrated that the national bank law protected the holders of national bank-notes from loss, but afforded no immunity against the occurrence of financial crises.

Banking in Germany.

Banking in Germany, up to the close of the Franco-German War, presented no peculiar features requiring attention. The Bank of Hamburgh was established in 1619, on the model of that of Amsterdam, as a purely deposit bank for the transfer of sums from the account of one individual to that of another; and its management appears to have been uniformly good. In the several German States banks were authorized under laws peculiar to each; and most of them were allowed to issue notes according to regulations varying from State to State. It followed that the notes of each bank were confined to its own neighbourhood; but the establishment of German unity was followed by a demand for a general banking law, and the establishment of a note currency that might circulate throughout the empire. After some discussion the Act of the 30th January 1875 was passed to satisfy these demands. Under this law an Imperial Bank was established, with an uncovered issue of 250 millions of marks (=£12,500,000); and thirty two banks were recognized as possessing rights of uncovered issue to the extent of 135 millions of marks (£6,750,000). The Imperial Bank is, however, allowed to increase its issue, subject to the condition that at least one-third is represented by cash in hand, and the remaining two-thirds by bills not having more than three months to run; while the other banks may also exceed their authorized issues subject to the payment of 5 per cent. interest on the excess above the authorized limit, *plus* the cash in hand, and weekly returns are required of the amount in circulation. No note is to be less than 100 marks (£5), and no new right of issue can be conceded except by a law of the empire. The State itself, however, under a law of April 1874, has the right to issue 120 millions of marks in State notes of small denominations. The working of this law has not yet been tested; but, if we may judge from our own experience, it will not produce any rapid withdrawal of local issues, and the unification of the note currency of the empire will not be accomplished. (L. H. C.)

BANKRUPTCY. When a person is unable to pay his debts in full, the law of civilized countries adopts some means of satisfying the creditors, as far as they can be satisfied, out of the debtor's estate, and relieving the debtor himself from pressure which, by his own efforts, he would not be likely to overcome. The debtor having been declared a bankrupt, his property vests in his creditors for the purpose of being rateably divided among them, and he thereupon starts a new man, entirely relieved from the obligations thus partially satisfied. Such, in general terms, is the process of bankruptcy as observed in modern societies. The law of bankruptcy is, in fact, a modern creation, slowly evolved out of the criminal code in answer to the necessities of a widely-spread industrial life. Early society is unanimous in treating inability to fulfil legal obligations as a most serious offence; and the harshness of ancient law towards debtors has been explained as a consequence of the fact that a contract was at first regarded as a sort of incomplete conveyance, and creditor and debtor as persons who respectively had and had not fulfilled their legal obligations. The early law of Rome, while prohibiting contracts of usury, still gives the legal creditors the savage remedy of dividing the carcase of their debtor or selling him and his family into slavery. Severe commercial distress endangering the stability of the state is of frequent occurrence in the history of Rome; but the law against debtors long retained its primitive severity. The Lex Pœtelia (about 326 B.C.) enabled a debtor, who could swear to being worth as much as he owed, to save his freedom by resigning his property; and many years after the legislation of Julius Cæsar established the *cessio bonorum* as an available remedy for all honest insolvents. The slow development of the law, and the practical difficulties with which each new adjustment was met, are copiously illustrated by the history of bankruptcy legislation in England. The first English statute on bankruptcy (34 and 35 Hen. VIII. c. 4) was directed against *fraudulent debtors*, and gave power to the lord chancellor and other high officers to seize their estates and divide them among the creditors. The 13 Eliz. c. 7 restricted bankruptcy to *traders*, and prescribed certain acts by committing which a trader became a bankrupt. Commissioners appointed by the lord chancellor are to seize the person of the bankrupt and divide his property among the creditors. The 4 Anne c. 17 and 10 Anne c. 15 took away the criminal character hitherto borne by the proceedings, and allowed a debtor, with the consent of a majority of his creditors, to obtain a certificate of having conformed to the requisitions of the bankrupt law, which, when confirmed by the chancellor, discharged his person and his after-acquired property from debts due by him at the time of his bankruptcy. The 6 Geo. IV. c. 16 allows a debtor to procure his own bankruptcy (an arrangement previously regarded as fraudulent), and introduces the principle of deeds of arrangement between debtor and creditors without a public bankruptcy. The 1 and 2 Will. IV. c. 56 established the Court of Bankruptcy, consisting of six commissioners, along with four judges as a Court of Review, and appointed official assignees to get in the bankrupt's estate on behalf of the creditors.

Various other statutes in the next twenty years made unimportant changes in the constitution of the court. In 1847 jurisdiction in bankruptcy was again restored to the Court of Chancery by the appeal being transferred to that court. The Bankrupt Law Consolidation Act, 1849, effected several important alterations in the system. Proceedings were to begin by a petition to the Court of Bankruptcy instead of a fiat out of Chancery. The commissioners were authorized to award certificates, classified according to the merit of the bankruptcy. In the first class the insolvency was declared to be due to misfortune; in the second, not entirely to misfortune; and in the third, not at all to misfortune. Certain specified offences deprived the bankrupt of all right to a certificate, and made him

liable to a criminal prosecution. The object of this arrangement was, of course, to meet fraudulent, or not entirely honest, attempts to obtain the benefit of a discharge of debts under the bankruptcy laws. It was not entirely successful, inasmuch as there was no settled principle observed in classifying the certificates, and the lowest class was, for all practical purposes, as good as the highest. The Act of 1849 also encouraged private arrangements by making a composition, accepted by nine-tenths of a bankrupt's creditors, binding upon the rest; but it was decided subsequently by the courts that, to make such a composition binding, it must be accompanied by a complete *cessio bonorum*. The next statute, the Bankruptcy Act, 1861, made non-traders subject to the law of bankruptcy, and empowered a majority in number, and three-fourths in value, of the creditors to bind the minority without a *cessio bonorum*. This arrangement was found to lead to private and fraudulent compositions, and in consequence by an Amendment Act in 1868 enlarged powers were given to non-assenting creditors. All this legislation still failed to give complete satisfaction. The complete exoneration of after-acquired property was denounced as unfair and likely to invite fraudulent bankruptcies, the system of arrangements with creditors was disliked, and the control of creditors over the property of the debtor and proceedings in bankruptcy was felt to be too small. The Bankruptcy Act, 1869, was passed after many unsuccessful attempts to deal with these complaints. It established a new Court of Bankruptcy, consisting of a chief judge, registrars, and other officers. The commissionerships were abolished, and the subordinate staff was to be transferred to the new court. The chief judge in bankruptcy is to be a judge of one of the Superior Courts of Law and Equity; and hitherto the office has been held by one of the acting vice-chancellors. Appeals from the county courts in bankruptcy go to the chief judge, and appeals from the chief judge to the Court of Appeal in Chancery, and thence occasionally to the House of Lords. Official assignees were abolished; and *trustees*, who should be creditors, are to be appointed to distribute the bankrupt's estate, while the creditors may appoint a committee of inspection to superintend the operations of the trustees. A comptroller in bankruptcy will receive the trustees' accounts after they have been audited by the committee, and take notice of any irregularity in the proceedings of the trustees. The law of reputed ownership was restricted to traders. Voluntary settlements by a trader, except in the case of property accrued in right of his wife, are void as against the trustee if the settler becomes bankrupt within two years after the settlement; and if he becomes bankrupt within ten years, it must be shown that, at the time of the settlement, he had sufficient property besides to pay his then existing debts, otherwise the settlement becomes void. A covenant by a trader, although made in consideration of marriage, for future settlement of property not then in any way belonging to him, is void as against the trustee, unless the property has been transferred or paid before the bankruptcy. The Act also introduces important alterations as to the discharge of the bankrupt. A bankrupt will not be discharged unless his estate has paid ten shillings in the pound, or a majority of the creditors (three-fourths in value) declare that the bankrupt is not responsible for the deficiency, and that they desire his discharge. If within three years the bankrupt makes up the dividend of ten shillings in the pound, he may have his discharge; and in the meantime his property will be protected from the creditors of the bankruptcy. If he fails to make up this dividend within three years, any debt remaining unpaid will become enforceable against his after-acquired property,—subject, of course, to the rights of creditors subsequent to the bankruptcy. There are provisions for compromising the bankruptcy by composition or liquidation by arrangement. The usual criminal clauses have been separated from the new statute of bankruptcy and appear in a separate enactment,—the Debtors' Act, 1869,—and the Court of Bankruptcy has no longer any criminal jurisdiction whatever. The Debtors' Act abolishes imprisonment for debt (except in certain cases in which the debt is mostly of the nature of a penalty), and provides for the punishment of certain misdemeanours of fraudulent debtors, whose affairs have come into bankruptcy. The prosecution takes place before the ordinary criminal tribunals. The Bankruptcy Act and the Debtors' Act become—by the repeal of previous statutes relating to insolvency, bankruptcy, and imprisonment for debt—a complete record of the legislation now in force on this subject.

Under the new statute all the county courts are constituted local courts of bankruptcy, while for the London district, as defined in the Act, there is the London Bankruptcy Court. All these courts are presumed to be the same court, and cases may be transferred from one to the other if necessary. Subject to this power of transfer, proceedings are to be taken against a debtor in the court of the district in which he resides; and if he does not reside in England and Wales, in the London court. By order of that court, or by resolution of the creditors, or by certificate of the local judge, cases may be transferred to the London court from any of the local courts. The chief judge, or a local judge, may delegate the powers (except the power of committing for contempt) to the registrar. All the courts of bankruptcy and their officers in England are to act in conjunction with bankruptcy courts in Scotland and Ireland, and with British courts having jurisdiction in bankruptcy elsewhere, the orders of one court being enforceable within the jurisdiction of the others. Section 72 of the Act gives to the new Court of Bankruptcy the important power "to decide all questions of priority, and all other questions of law or fact arising in any case of bankruptcy coming within the cognizance of such court, or which the court may deem it expedient or necessary to decide, for the purpose of doing complete justice or making a complete distribution of property in any such case." By this enlarged jurisdiction the court has power to decide, even as against strangers, questions arising in the bankruptcy; and it has been held that it may restrain proceedings in Chancery or at Common Law, and even out of the jurisdiction. The judge may, at the request of parties, or of his own discretion, direct issues of fact to be tried by a jury.

By the Bankruptcy Act, 1861, the special legislation relating to insolvent debtors was abolished. Up to that time *traders* only had been allowed the relief of bankruptcy, and all other insolvent debtors remained liable to their creditors for the unpaid portion of their debts. They might be kept in prison during the creditors' pleasure, and any property they might acquire was available for the satisfaction of the creditors' claims. From time to time special Acts were passed for the liberation of insolvent debtors confined in prison, a general Act (53 Geo. III. c. 102) was tried for a limited period and repealed, and finally, by 1 and 2 Vict. c. 110, a court was established for the "relief of insolvent debtors," their discharge, of course, being conditional on the surrender of their property for the benefit of their creditors. The principle of the distinction thus maintained between the trader and the non-trader was, that the creditors of the former were to be regarded as to some extent partners in his speculations, while the latter was alone responsible for his insolvency; and it was feared that the discharge of bankruptcy, if allowed as a means of satisfying private debts, might give great encouragement to extravagance and fraud. On the abolition of the

Insolvents' Court in 1861, all insolvent debtors were admitted to the relief of bankrupt's discharge, but a distinction is still made on several important points between traders and non-traders. A schedule to the Act of 1860 gives a list of the different occupations which are to be considered as "trades," and the exception is expressly stated that "a farmer, grazier, common labourer, or workman for him, shall not, nor shall a member of any partnership, association, or company, which cannot be adjudged bankrupt under this Act, be deemed as such a trader for the purposes of this Act." The liability to bankruptcy may therefore be said to be now almost co-extensive with the capacity to make a contract. Persons who cannot make a binding contract, *e.g.*, married women, minors, lunatics, &c., cannot be made bankrupts. But where this incapacity is removed (as for example in the city of London, where by custom a married woman may trade as a *femme sole*), the liability to bankruptcy will arise.

Proceedings in bankruptcy are now begun by a petition from one or more creditors (claiming not less than £50), alleging that the debtor in question has committed an act of bankruptcy, and praying that he may be adjudged a bankrupt. The following are "acts of bankruptcy:"—(1.) If the debtor has assigned his property to trustees for the benefit of his creditors; or (2), has made a fraudulent conveyance of any of his property; or (3), with intent to defeat his creditors, has departed from or remained out of England; or, being a trader, has left his dwelling-house, or begun to keep house, or suffered himself to be outlawed; or (4), has filed a declaration of inability to pay his debts; (5.) If execution for not less than £50 has been levied by seizure of goods (in the case of a trader); (6.) If the creditor has served a "debtors' summons" for not less than £50, and the debtor has for three weeks (or if a trader, for seven days) neglected to pay or compound for the same. The adjudication must be asked for within six months of the act of bankruptcy, and the petitioning creditor's debt must be for a liquidated (*i.e.*, ascertained) sum due at law or in equity, and must not be a secured debt unless the security is given up for the benefit of the creditors. Should the alleged debtor deny his indebtedness, the court may dismiss the summons or direct the issue to be tried by itself or some other competent court; and similar proceedings take place when the debtor appears to the creditors' petition and repudiates his indebtedness.

The consequence of adjudication is that all the bankrupt's property vests in the registrar of the court, until the appointment by the creditors of a trustee, and thereafter in the trustee. The word property has been expressly defined to include money, goods, things in action, land, and every description of property, whether real or personal, also obligations, ornaments, and "every description of estate, interest, and profit, present or future, vested or contingent, arising out of, or incident to, property as above defined." The adjudication "relates back" to the time of the "act of bankruptcy." The bankrupt may retain the tools of his trade and the necessary clothing and bedding of his family to the extent in all of £20. It is the duty of the trustee to discover, take possession of, realize, and distribute the bankrupt's property; and, subject to the provisions of the Bankruptcy Act, he must follow the directions of the committee of inspection or the creditors. The bankrupt is required to aid in the administration. He must procure a statement of his affairs, and submit to a public examination thereon. A bankrupt under examination is not, like a witness in other courts, protected from questions tending to inculpate himself, although he cannot be compelled to answer a question whether he has done some specific act clearly of a criminal nature. His answers may afterwards be used as evidence against him on a criminal charge. The bankrupt cannot now be arrested or imprisoned except for attempts to leave the country, avoid appearance, remove or conceal his goods, &c., or, after adjudication, for removing goods above the value of £5, or failing to attend examination, or committing contempt of court. If a member of the House of Commons is adjudged bankrupt, he becomes incapable of sitting or voting for one year after the adjudication, unless within that time the bankruptcy is annulled or the creditors satisfied. If on the expiration of a year neither of these events has taken place, the court certifies the fact to the speaker, and the seat of the bankrupt member thereupon becomes vacant. A bankrupt peer is disqualified from sitting or voting in the House of Lords, unless and until his bankruptcy is annulled on the ground that the order of adjudication ought not to have been made, or the bankrupt is discharged by actual payment or satisfaction in the prescribed mode from all debts and liabilities due at the date of his bankruptcy. The conditions on which a bankrupt may obtain his discharge have been already stated. The discharge releases the bankrupt for all debts provable under the bankruptcy, except debts due to the Crown, or for offences against the revenue, and debts incurred by means of fraud or breach of trust. The court has power to annul the bankruptcy on various grounds, but in that case all acts properly done by the trustee in reference to the property of the bankrupt will now remain valid. A partnership may be adjudged bankrupt, and the general rule of distribution is that the joint creditors have priority of payment out of the joint or partnership property, and the separate creditors out of the separate estate.

A less public form of bankruptcy is also sanctioned by the Act of 1869. By § 125 it is provided that the creditors of a debtor may declare (by a majority in number and three-fourths in value) that his affairs are to be liquidated by arrangement and not in bankruptcy. By § 126 the creditors may, by a resolution under the same conditions, resolve that a composition shall be accepted in satisfaction of the debts due to them by the debtor. If liquidation is resolved on, every creditor, whether having notice of the meeting or not, is absolutely restrained from taking any proceedings for recovering his debt, unless it appears to the court that his debt is prejudicially affected by the resolution; otherwise under liquidation or composition, the court may restrain or permit other legal processes on respect of provable debts as it thinks fit.

In Scotland, as in England, the law of bankruptcy arose as a remedy against the frauds of insolvent debtors. It was declared by an Act of the Scottish Parliament (1621, c. 18) that no debtor after insolvency should fraudulently diminish the fund belonging to his creditors, and if a deed of assignment was gratuitously executed after the contracting of debt in favour of a near relation or a confidential friend, fraudulent dealing was to be presumed. The Act 1696, c. 5, settled the definition of a notour or notorious bankrupt, a question which had previously engaged the attention of the judges of the Court of Session. The statute defines "a notour bankrupt" to be any debtor who, being under diligence by horning or caption, at the instance of his creditors, shall be either imprisoned, or retire to the abbey or any other privileged place, or flee or abscond for his personal security, or defend his person by force, and who shall afterwards be found, by sentence of the Lords of Session, to be insolvent. Bankruptcy as thus defined was, it is said, intended to afford a remedy against fraudulent preference by debtors, and not as the ground-work of a general process of distribution, although by later statutes it became a necessary requisite of every such process. The exceptions recognized in the Act of 1696, of persons absent from Scotland, and therefore not liable to imprisonment, or of persons exempted therefrom by special privileges,

were removed by later legislation. The English distinction between traders and non-traders, it will be observed, is not recognized in Scotch law. The statute made null and void all voluntary dispositions, assignations, and other deeds at or after or within sixty days before bankruptcy. The principal Bankruptcy Act now in force is the 19 and 20 Vict. c. 79 (amended by 20 and 21 Vict. c. 19, and 23 and 24 Vict. c. 33).

By section 9 of the principal Act, notour bankruptcy is now constituted—

1. By sequestration (or adjudication in England and Ireland); and

2. By insolvency concurring either—(*a*) with a duly executed charge for payment followed by imprisonment or apprehension, or flight or retreat to sanctuary, by execution of arrestment of debtor's effects, not discharged within fifteen days, by execution of poinding of any of his movables, or by decree of adjudication of any part of his movable estate; or (*b*), with sale of effects belonging to the debtor under a poinding or under a sequestration for rent, or retiring for twenty-four hours to the sanctuary, or making application for the benefit of *cessio bonorum*.

Notour bankruptcy continues, in cases of sequestration, until the debtor has obtained his discharge, and in other cases until insolvency ceases. Sequestration may be awarded of the estate of any person in the following cases:—

1. Living debtor subject to jurisdiction of Scotch courts,—(*a*), on his own petition with concurrence of qualified creditors; or (*b*), on petition of qualified creditors, provided he be a notour bankrupt, and have had a dwelling-house or place of business in Scotland within the previous year.

2. In the case of a deceased debtor, subject at his death to the jurisdiction of the court,—(*a*), on the petition of his mandatory; or (*b*), on the petition of qualified creditors (§ 13).

Sequestration may be awarded either by the Court of Session or by the sheriff. A sequestration may be recalled by a majority in number and four-fifths in value of the creditors, who may prefer to wind up the estate by private arrangement. If the sequestration proceeds, the creditors hold a meeting, and by a majority *in value* elect a trustee to administer the estate, and three commissioners (being creditors or their mandatories) to assist and control the administration and declare the dividends. The bankrupt (under pain of imprisonment) must give all the information in his power regarding his estate, and he must be publicly examined on oath before the sheriff; and "conjunct and confident persons" may likewise be examined. The bankrupt may be discharged either by composition or without composition. In the latter case (1) by petition with concurrence of all the creditors, or (2) after six months with concurrence of a majority and four-fifths in value of the creditors, or (3) after eighteen months with concurrence of a bare majority in number and value, or (4) after two years without concurrence. In the last case the judge may refuse the application if he thinks the bankrupt has fraudulently concealed his effects, or wilfully failed to comply with the law.

The procedure in *cessio bonorum* is regulated by 6 and 7 Will. IV. c. 56 (which gave jurisdiction to sheriffs) and Act of Sederunt of June 1839. A debtor who is or has been in prison, or has had a warrant of imprisonment served against him, may present a petition setting forth his inability to pay his debts, and his willingness to surrender his estate, and praying for interim protection. The debtor is examined by the sheriff on oath, and the creditors may be heard against the petition. A decree of *cessio bonorum* operates as an assignation of a debtor's movables to a trustee for behoof of creditors. The bankrupt under a *cessio* has no power to insist on his discharge, and therefore cannot protect his subsequent acquisitions against his creditors. By the late statute a majority of the creditors (subject to review by the court) may, in certain cases, resolve that the bankrupt shall be entitled to apply for a decree of *cessio* only, and not to a discharge in the sequestration, and the court may grant the *cessio* in the sequestration without requiring a new process.

By the Bankruptcy (Ireland) Amendment Act, 1872 (35 and 36 Vict. c. 58), the law of Ireland has been assimilated to the new system established by the English Bankruptcy Act, 1869. (E. R.)

Bankruptcy in the United States.

In the United States, Congress alone has power to pass a bankrupt law which shall have authority throughout the country. The several States may enact such statutes when there is no law of Congress in operation; but these statutes will fully bind only the citizens of the State which enacts it. There is no power to obtain effectual control of property without its limits so as to prevent local preferences; nor can the State laws discharge contracts due to non-residents. The general Government has made so little use of the power confided to it, that many of the States were obliged to pass bankrupt laws, notwithstanding the imperfection of their operation in some cases, and those, often, the most important in the interests involved. Massachusetts had an excellent system, established in 1838, which is specially mentioned because the Act of Congress is largely drawn from this source. All State laws on the subject are suspended while a general law of bankruptcy is in force.

The first general Bankrupt Act was passed in 1800, and repealed in 1803. In 1841 another law was put in operation, with a special view of meeting the urgent needs of debtors who had been ruined by the commercial revulsion of 1837–38, and who could receive no effectual relief from local laws. This Act was repealed in thirteen months; but in the meantime a very large number of cases had been disposed of, amounting, for example, to 3250 in Massachusetts alone. The law now in operation took effect June 1, 1867. It was framed with much care by a committee of the House of Representatives, of which Mr Jenckes, of Rhode Island, was the chairman and chief working member. Its authors hoped that it would form a permanent addition to the commercial jurisprudence of the country.

The administrative machinery is simple. The district courts, which have always had the original jurisdiction of causes in admiralty, revenue, and other national matters, are made courts of bankruptcy. The judge of each district ascertains how many registers are needed for the convenient despatch of causes in his territory, and they are appointed by the chief justice of the United States and the district judge concurrently. The registers have, by law, functions chiefly administrative and ministerial; but they, in fact, hear and decide many judicial questions by consent of the parties, and subject to the revision of the judge. In proceedings in bankruptcy proper, such as adjudications, discharges, proof of debts, marshalling assets, there is an appeal from the district to the circuit court, and no farther. Actions at law, or suits in equity, to which assignees in bankruptcy are parties, may be brought either in the State or the Federal courts. If in the latter, the whole case if in equity, or the law points in an action at law, may be carried to the Supreme Court at Washington when the amount in dispute exceeds $5000, or questions of law, which the judges of the circuit court consider doubtful, may be certified by them to the Supreme Court, whatever may be the amount involved; and all decisions of the highest court of a State, involving questions of law under the Bankrupt Act, may be reviewed by the Supreme Court, if adverse to

the right or title set up under that statute. In some of these various modes the principal questions arising under the Act will in time be settled by the highest judicial authority, and thus uniformity of decision will be secured.

The statute covers the whole ground of bankruptcy and insolvency. It is applied to all debtors, whether traders or not, and to debtors petitioning for its benefits, as well as to those proceeded against by creditors. Any one who owes $300 may petition, and any such debtor who has committed certain specified acts may be adjudged bankrupt *in invitum.* The acts of bankruptcy are substantially alike in all such statutes in England and the United States, and tend to prove either frudulent conduct or hopeless insolvency, such as concealing property, conveying it fraudulently, departing the district with intent to defraud creditors, lying in prison for twenty-one days. There is nothing analogous to the trader debtor summons, though the Act of 1800, and the Massachusetts law of 1838, admitted a somewhat similar test of bankruptcy. This law, however, has adopted one which to a considerable extent supplies this want, by declaring a merchant, trader, banker, broker, manufacturer, or miner to be bankrupt who has suffered his commercial paper to remain overdue and unpaid for forty days. No other distinction is made between traders and other debtors, excepting that merchants and tradesmen are bound, under pain of being denied their discharge, to keep proper books of account.

The property of the bankrupt is assigned by the judge or register to the persons chosen by the majority in number and value of the creditors—the court having full power to overrule the choice of the creditors, or to add an assignee to those chosen. The assignment is conclusive evidence of the assignees' authority, and cannot be collaterally impeached on any ground, excepting want of jurisdiction in the bankrupt court, nor in any suit whatever. This most valuable rule was adopted by Massachusetts in 1838, and has saved an enormous amount of useless litigation. There is no danger of injustice from it, because the adjudication against a bankrupt is never made without notice to him, nor without a trial by jury, if he demands one; and any person having an interest adverse to the adjudication has a right to be heard as well as the debtor.

The doctrine of the relation of the assignee's title to an act of bankruptcy committed in the country has not obtained in the United States. That title relates, as in other suits, to the beginning of the proceedings,—that is to say, the day and hour that the petition, whether voluntary or involuntary, is filed. The most marked difference between the English and American statutes, or rather between the practical working of them, is in the extension given by the latter to the doctrine of preference. By the law of 1867 and its amendments, the assignee can avoid all advantages given to pre-existing creditors within four months (in involuntary cases, within two months) before the filing of the petition, if the bankrupt was then insolvent, and intended a preference, and the preferred creditor knew the insolvency and the intent, no matter what pressure, by suit, threat, or otherwise, may have been brought to bear upon the debtor. This law, as construed, operates almost like a relation back of the assignee's title, so far as pre-existing creditors are concerned, unless the payments or settlements have been made in the ordinary course of business, and sometimes, though rarely, when they have been so made. This rule is a logical development of the law of preference, as established in Lord Mansfield's time, and still continued in England. When it is considered that a preference is a technical fraud, and may be charged as an act of bankruptcy and as a valid objection to the debtor's discharge, it will be readily seen that the conduct of debtors in failing circumstances must be much restrained and regulated, to the advantage of the general creditors, by the perils that attend a partial or unfair mode of settlement, or even a struggle to continue business after recuperation has become hopeless. Such was found to be the operation of a similar law in Massachusetts, where it prevailed for more than twenty years before the statute of that State was suspended by the general Bankruptcy Act of 1867.

The discharge of the debtor is granted or refused by the court absolutely. There are no grades or classes of certificates, and no power to suspend action upon the question, and put the debtor on probation. In voluntary bankruptcies 30 per cent. must be paid in dividends, or the consent of one-fourth in number and one-third in value of the creditors must be obtained. Any creditor may oppose the decree of discharge for fraud committed or continued within six months before the petition, for loss by gaming, and in the case of merchants and tradesmen, as we have seen, for failure to keep suitable accounts. The discharge when granted, is, like the assignment, unimpeachable in any court; but it may be reviewed within two years by the court that granted it, upon evidence afterwards discovered.

The title, powers, and duties of the assignee, the mode of settling joint and separate estates, and marshalling debts and assets, are substantially similar under the English and American systems. The title of the assignee, however, does not depend at all, in any case, upon the date of the petitioning creditor's debt. The misdemeanours created by the law were taken, with some modifications, from the felonies of the English Act in force in 1867. The mode of compounding with creditors has recently been adopted from the English statute of 1869, and has been largely used with good results.

Whether or not the bankrupt law will take its place as part of the settled policy of the country cannot be easily predicted. It is not likely to be displaced until the existing commercial depression has been relieved. After that time much will depend upon the degree of care and economy with which it is administered, and the readiness of Congress to adopt modifications that shall be found to be necessary, but most upon the opinion that the debtors of the country may entertain of its operation. The law was considerably modified in 1874 in the interest of debtors, by making adjudications *in invitum* more difficult, and discharges more easy; but the law is still popular with creditors, because of the serious check it imposes upon local preferences. It is likewise approved by those lawyers and judges who have had the most to do with its administration; and it is not improbable that the effect of a few years more of its operation may be to render it indispensable to the commercial world. (J. L.)

BANKS, Sir Joseph, for upwards of forty years president of the Royal Society of London, was born in Argyle Street, London, on the 13th of February 1743. He was the only son of William Banks, a gentleman of considerable landed property, whose father had derived his fortune principally from successful practice as a physician in Lincolnshire, had been on one occasion sheriff of that county, and had for some years represented Peterborough in parliament. Very little is known of Joseph's early life and education. He appears to have been sent at the age of nine to Harrow, and after spending four years there, was removed to Eton. Here he seems first to have acquired a taste for botanical pursuits, and was accustomed to spend all his leisure hours in the beautiful lanes and fields round the school. He carried the same fondness for natural history to Oxford, where he was entered as a gentleman commoner of Christ's College; and by his exertions a lecturer on natural science was for the first time brought into the university. After taking an honorary degree he left Oxford; and at the age of twenty-one he found himself possessed of ample means,

his father having died in 1761. Three years later he made his first scientific expedition to Newfoundland and Labrador, and brought back a rich collection of plants and insects. Shortly after his return, Government resolved to send out Captain Cook to observe the transit of Venus in the Pacific Ocean, and Banks, through the influence of his friend Lord Sandwich, obtained leave to join the expedition. He made the most careful preparations, in order to be able to profit by every opportunity, and induced Dr Solander, a distinguished pupil of Linnæus, to accompany him. He even engaged draughtsmen and painters to delineate such objects of interest as did not admit of being transported or preserved. The voyage occupied three years, and many hardships had to be undergone; but the rich harvest of discovery—many natural phenomena being for the first time brought to light—was more than adequate compensation. Banks was equally anxious to join Cook's second expedition, and expended large sums in engaging assistants and furnishing the necessary equipment; but, owing to ill-feeling on the part of some Government officials, he was compelled to relinquish his purpose. He, however, employed the assistants and materials he had collected in a voyage to Iceland, returning by the Hebrides and Staffa, the geological formation of which he was the first to describe. In 1778 Banks was elected president of the Royal Society, of which he had been a fellow from 1766. His predecessor had been compelled to resign owing to some disagreement with the court, but Banks was always a favourite with the king. In 1781 he was made a baronet; in 1795 he received the Order of the Bath; and in 1797 he was admitted to the Privy Council. During the long tenure of his office as president, Sir Joseph did much to raise the state of science in Britain, and was at the same time most assiduous and successful in cultivating friendly relations with scientific men of all nations. His kindness and liberality were beyond praise, and he was most generous in affording to other naturalists the free use of his vast materials. It has, however, been made matter of objection to him, that from his own predilections he was inclined to overlook and depreciate the labours of the mathematical and physical sections of the Royal Society. Sir Joseph died on the 19th March 1820, at the age of 77. He bequeathed his valuable collections of books and botanical specimens to the British Museum. His only writings are two small tracts of little importance; he seems to have given up his intention of writing an elaborate treatise after the death of his friend and fellow-labourer, Dr Solander. His fame rests mainly on his numerous discoveries in botany and natural history. See Cuvier, *Éloge Historique de M. Banks*, 1821.

BÁNKURÁ, a district of British India, within the Bardwán division, under the Lieutenant-Governor of Bengal, situated in 22° and 23° N. lat., and 86° and 87° E. long., bounded on the N. and E. by Bardwán district; on the S. by Midnapur district; and on the W. by Mánbhúm district. Bánkurá forms a connecting link between the delta of the Ganges on the E. and the mountainous highlands of Chhotá Nágpur on the W. Along its eastern boundary adjoining Bardwán district the country is flat and alluvial, presenting the appearance of the ordinary paddy lands of Bengal. Going N. and W., however, the surface gradually rises into long undulating tracts; rice lands and swamps give way to a region of low thorny jungle or forest trees; the hamlets become smaller and more scattered, and nearly disappear altogether in the wild forests along the western boundary. The principal hills are—Mánjiá hill, on the south bank of the Dámodar; Koro hill, S. of the foregoing; Susuniá hill, W. of Koro; and Behárináth hill, in the N.W. corner of the district. The rivers are merely mountain torrents—the largest, the Dámodar, being only navigable by country boats during the rains. The census of 1872 returned the population of the district at 526,772 souls, inhabiting 2028 villages, and 104,687 houses; average density of population, 391 to the square mile. The Hindus numbered 487,786, or 92·6 per cent. of the total population; Mahometans, 13,500; Christians, 70; and persons of unspecified religion, chiefly aboriginal tribes, 25,416.

District area, after recent transfers to and from the districts of Bardwán and Mánbhúm in 1872, 1346 square miles. Before these transfers the area was returned at 1350 square miles, of which 630 were said to be cultivated, 540 cultivable but not cultivated, and 180 uncultivable waste. Agricultural products—rice, barley, cotton, indigo, oil-seeds, and pulses. Minerals—coal, lime, and building stone. In its manufactures, the district is noted for fine descriptions of coloured silk cloths. Exports—rice, oil-seeds, lac, tamarind, silk cloth, silk cocoons, &c. Imports—English piece goods, salt, tobacco, spices, cocoa-nuts, turmeric, and different kinds of pulses. Chief trading towns and seats of commerce—Bánkurá, Bishnupur, Rájgrám, and Barjorá. Three main lines of road traverse the district. The total revenue increased from £40,934 in 1835–36 to £66,392 in 1870–71, and the civil expenditure from £8006 to £17,487 within the same period. Bánkurá is a permanently settled district. In 1870–71 the district contained 910 estates, held by 1351 proprietors, and paying a total Government land revenue of £45,362. Besides the land revenue, the following are returned as the other sources of revenue in 1870–71, viz., assessed taxes, £5455; excise, £3167; stamps, £6787; law and justice, £30,478; law charges, £62; and local and provincial funds, £2512. The police force in 1871 numbered 5681 men, maintained at a cost of £23,656. The district contained 515 schools in 1871–72, attended by 14,676 pupils; maintained at a total cost of £4602, of which Government paid £1291. The climate of Bánkurá is generally healthy, the cold season being bracing, the air wholesome and dry, and fogs of rare occurrence. The temperature in the hot season is very oppressive and relaxing. Rainfall in 1868, 61·25 inches; minimum temperature in the same year, 62°; maximum, 98°. The prevailing diseases in the district are intermittent fever, leprosy, and occasionally diarrhœa and dysentery. Cholera visited the district in an epidemic form in the years 1855, 1860, 1864, 1866–67, and 1869, that of the first year being the severest. Bánkurá suffered greatly from the famine of 1865–66. Two towns contain a population of upwards of 5000—1. Bánkurá, the administrative headquarters; population, 16,794; municipal income in 1872, £551; expenditure, £476. 2. Bishnupur—population, 18,047; municipal income, £273; expenditure, £192. The Bishnupur Ráj was one of the largest estates in Bengal in the end of the last century, but it was sold for arrears of revenue shortly after the conclusion of the permanent settlement in 1793.

BÁNKURÁ, the principal town of the district of the same name, in 23° 14′ N. lat., and 87° 6′ 45″ E. long., stands on an elevation on the left bank of the River Dhalkisor. It has a bázár, a spacious building for the accommodation of travellers, and the district courts, school, jail, post-office, &c. In 1872 the population amounted to 16,794.

BANN, a considerable river of Ireland, which rises in the Mourne Mountains, County Down, and falls into Lough Neagh. From this it emerges as the Lower Bann, and, flowing between the counties of Antrim and Londonderry, falls into the Atlantic, four miles S.W. of Portrush. The Upper Bann is navigable for vessels of 50 tons to its junction with the Newry canal, a little above Portadown. The Lower Bann flows in a northerly direction; it is navigable up to Coleraine for vessels of 200 tons, but the bar at its mouth renders it difficult of access in rough weather, and its course is broken by a fall of 13 feet about a mile above Coleraine. The salmon and eel fisheries are of considerable value. Measured in a direct line, the Upper Bann is about 35 miles long, and the Lower 30 miles.

BANNERETS. In the early ages of chivalry there were two kinds of knights, called respectively *Bachelors* and *Bannerets*. The former carried pennons terminating in a point or points; the latter, banners,—that is to say, pennons rendered square by having the points cut off. This process of converting the pennon into the banner was done by the sovereign himself on the field of battle, standing beneath his own royal standard displayed. The distinction, awarded for peculiar gallantry, was a very high one; and those who

enjoyed it ranked above all other knights except those of the Garter. The banner bore the coat armour of the banneret himself, and served as an ensign for the followers and retainers whom he took with him into the camp or court. The king himself and the greatest nobles were members of the order; and we have in the Roll of Caerlaverock the blazon of nearly one hundred bannerets (including the king, eleven earls, and the bishop of Durham) who were present with Edward I. in his campaign against Scotland in 1300. The etymology of the word is clear; and Selden, after expressing his opinion that *baro* is equivalent to *vir*, remarks that "the Germans have also the name of *banner-heer* or *panner-heer*, as if you would say *dominus vexillifer*, or the like, or as the title of banneret" (*Titles of Honour*, part ii. 1, 52). Nevertheless the term banneret, either from simple misapprehension or in order to mark the relative rank of the knight, has been translated *baronettus* (quasi *baro minor*) in some old statutes; and the historian Walsingham, in describing the prisoners at the battle of Stirling, speaks of *Barones et Baronetti viginti duo*, &c. Indeed, in a patent granted to Sir Ralph Vane so late as 4 Edward VI., his grade of banneret is Latinized by *Baronettus*. In France, it is said, the dignity was hereditary; but in England it died with the person who gained it. On the institution of baronets by King James I., the order dwindled and at length became extinct. The last banneret created was Sir John Smith, who received the dignity after the battle of Edgehill, for his gallantry in rescuing the standard of Charles I.

BANNOCKBURN, a village of Scotland, on the Bannock, an affluent of the Forth, three miles S. of Stirling. In 1871 its population amounted to 2564, principally employed in the manufacture of tweeds and carpets. In the neighbourhood, on the 24th of June 1314, was fought the memorable battle which secured the independence of Scotland, and established Bruce upon the throne. A fragment of the "bore stone" in which the royal standard was placed, is still to be seen, protected by an iron framework. At Sauchieburn, in the neighbourhood, James III. was defeated by his subjects in 1488. See SCOTLAND.

BÁNSWÁRÁ (literally, the forest country), a Rájput feudatory state under the Mewár agency in Rájputáná, extends from 23° 10′ to 23° 48′ N. lat., and from 74° 2′ to 74° 41′ E. long. It borders on Gujarát, and is bounded on the N. by the native states of Dungarpur and Udaipur or Mewár; on the N.E. and E. by Pratábgarh; on the S. by the dominions of Holkár and the state of Jabuá; and on the W. by the state of Ríwákánta. Bánswárá State is about 45 miles in length from N. to S., and 33 miles in breadth from E. to W., and has an area of 1440 square miles, with an estimated population of 144,000 souls. The Mahi is the only river in the state, and great scarcity of water occurs in the dry season. The Mahárávval, as the chief is called, has, however, undertaken the digging of wells, tanks, &c., to meet this want. The Bánswárá chief belongs to the family of Udaipur. During the vigour of the Dehli empire Bánswárá formed one of its dependencies; on its decline the state passed under the Marhattás. Wearied out by their oppressions, its chief in 1812 petitioned for English protection, on the condition of his state becoming tributary on the expulsion of the Marhattás. The treaty of 1818 gave effect to this arrangement; England guaranteeing the prince against external enemies and refractory chiefs; he, on his part, pledging himself to be guided by her representative in the administration of his state. There are 33 tributary chiefs or Thákurs of this state, and the whole strength of force kept up in 1870–71 was 617 men. Indian corn, wheat, pulses, rice, and other kinds of millet form the chief products of Bánswárá. The revenue of the state amounted to £17,595 in 1870–71, exclusive of £3301 set apart for the personal expenditure of the chief and his family. The total expenditure in the same year amounted to £16,745. An annual tribute of £3997, or 50,000 Salímsháhí rupees, is paid by the chief to the British Government. The custom of *satí*, or widow-burning, has long been abolished in the state, but the people retain all their superstitions regarding witches and sorcery; and as late as 1870, a Bhil woman, about 80 years old, was swung to death at Kusalgarh in Bánswárá, on an accusation of witchcraft. The perpetrators of the crime were sentenced to five years rigorous imprisonment, but they had the sympathy of the people on their side. The chief town is Bánswárá, lat. 23° 30′ and long. 74° 24′, situated about 8 miles W. of the Mahí river, surrounded by an old disused rampart, and adorned by various Hindu temples, with the battlements of the chief's palace overlooking it.

BANTAM, a decayed town of Java, formerly capital of a district of the same name, at the north-western extremity of the island, situated on the Bay of Bantam, near the mouth of a river which falls into the bay. It was once a large, rich, and flourishing city, but is now mostly in ruins. It is about 61 miles W. of Batavia, and is situated on a low, swampy beach, surrounded by jungle, and intersected by stagnant streams, so that its climate is even more unhealthy than that of Batavia was in the last century. Prior to the Dutch conquest Bantam was a powerful Mahometan state, whose sovereign extended his conquests in the neighbouring islands of Borneo and Sumatra. In 1595 the Dutch, under Houtmann, expelled the Portuguese, and formed their first settlement. An English factory was established in 1603, and continued to exist till the massacre of the agents in 1677. In 1683 the Dutch reduced the sultan to vassalage, built the fort of Spielwyk, and monopolized the port, which had previously been free to all comers; and for more than a century afterwards Bantam was one of the most important seats of commerce in the East Indies. In 1811 after Batavia had surrendered to the British, Bantam soon followed; but it was restored to the Dutch in 1814. Two years later, however, they removed their chief settlement to the more elevated station of Serang, or Ceram, seven miles inland, and in 1817 the ruin of Bantam was hastened by an extensive conflagration. The Bay of Bantam was formerly a commodious retreat for vessels; but it is now so choked up with daily accessions of soil washed down from the mountains, as well as by coral shoals extending a considerable way to the eastward, that it is inaccessible to vessels of any considerable burden. Long. 106° 3′ E., lat. 6° 4′ S.

BANTRY, a small seaport situated on Bantry Bay, on the S.W. coast of Ireland, in the county of Cork. Lat. 51° 39′ N., long. 9° 24′ W. The trade of this port, formerly considerable, is now almost confined to the exportation of grain. The pilchard fishery was once very productive, but the fish has now deserted the coast. The population, which in 1831 was 4276, had decreased in 1871 to 2441 (including 409 in the island of Whiddy). The bay of the same name is about 25 miles long by 4 to 6 broad, has from 10 to 30 or 40 fathoms of water, and is surrounded by high mountains. It affords a very fine harbour for shipping, and contains two small islands, Bear and Whiddy. In 1796 a French fleet anchored here with the view of invading Ireland, and landed eight men, who were immediately taken prisoners.

BANU, a district of British India, under the Lieutenant-Governor of the Panjáb, lies between 33° 15′ 30″ and 32° 10′ 30″ N. lat., and 72° 1′ and 70° 27′ E. long. It is bounded on the N. by the Khatábí hills, separating it from the district of Kohát, and by a corner of the Rawál Pindí district; on the E. by the districts of Jhilam and Sháhpur; on the S. by the district of Derá Ismáil Khán; and on the

W. by the Wazírí hills. Total area, 3148 square miles. Population, 287,547: consisting of Hindus, 26,222, or 9·12 per cent.; Mahometans, 260,550, or 90·61 per cent.; Sikhs, 493; others, 282; density of population per square mile, 91. The principal tribes inhabiting the district are—(1.) Wazírí Patháns, recent immigrants from the hills, for the most part peaceable, and good cultivators; (2.) Banuchís, inhabitants of Banu proper; (3.) Pathans, criminal and depraved, with all the vices and few of the virtues of their race, but fair cultivators; and (4.) Murátí Patháns, inhabitants of the Erákhel valley, a fine manly race, truthful and industrious.

The Indus flows through the district from north to south, dividing it into two portions. The other streams are the Kúram (which falls into the Indus) and its tributary the Gambilá. The course of the Indus is very capricious, and has a tendency to encroach eastwards. During inundations its vast body of waters stretches for many miles across the country. Principal crops of Banu district: wheat, barley, gram, and pulses for the spring harvest; millet, Indian corn, sugar-cane, cotton, and oil-seeds, for the autumn harvest. Average produce of land per acre in ℔:—Rice, 369 ℔, cotton, 100; sugar, 1394; tobacco, 512; wheat, 480; other inferior grains, 640; oil-seeds, 240; fibres, 87. Cultivated area of the district in 1871–72, 450,519 acres; uncultivated and pasture grounds, 414,607; cultivable, 58,562; uncultivable, 1,092,193; total, 1,565,662 acres, or 2446 square miles reported on. Revenue from all sources in 1871–72, £50,218, of which £42,741 was derived from the land. The first regular settlement of the land revenue commenced in 1871-72, and is still (1874) in progress. A police force of 464 men of all grades is maintained, of whom 395 belong to the imperial, 57 to the municipal, and 12 to the primitive police. The district contained 33 schools in 1871-72, attended by 1152 pupils. The principal towns are—Trakhel, population, 7446; Kálábágh, 6419; Edwardesábád (Banu), 3185; Bhangi-khel, 5339; Nimal, 5010; and Ván Bachrán, 6178.

BANYAN TREE (*Ficus indica*, Linn., *Urostigma benghalense*, Gaspar.) is a native of several parts of the East Indies and Ceylon. It has a woody stem, branching to a great height and vast extent, with heart-shaped entire leaves terminating in acute points. Every branch from the main body throws out its own roots, at first in small tender fibres, several yards from the ground; but these continually grow thicker until they reach the surface, when they strike in, increase to large trunks, and become parent trees, shooting out new branches from the top, which again in time suspend their roots, and these, swelling into trunks, produce other branches, the growth continuing as long as the earth contributes her sustenance. On the banks of the Nerbudda, according to Forbes's *Oriental Memories*, stands a celebrated tree of this kind, which is supposed to be that described by Nearchus the admiral of Alexander the Great. This tree once covered an area so immense, that it has been known to shelter no fewer than 7000 men. Though now much reduced in size by the destructive power of the floods, the remainder is still nearly 2000 feet in circumference, and the trunks large and small exceed 3000 in number.

BAPHOMET, the imaginary symbol or idol which the Knights Templars were accused of worshipping in their secret rites. The term is supposed to be a corruption of *Mahomet*, who in several mediæval Latin poems seems to be called by this name. Von Hammer wrote a dissertation in the *Mines de l'Orient*, 1818, in which he revived the old charge against the Templars. The word, according to his interpretation, signifies the baptism of *Metis*, or of fire, and is, therefore, connected with the impure rites of the lowest Gnostic sects, the Ophites. Additional evidence of this, according to Von Hammer, is to be found in the architectural decorations of the Templars' churches. An elaborate and, so far as has yet appeared, successful criticism of Von Hammer's arguments was made in the *Journal des Savans*, March and April 1819, by M. Raynouard, well known as the defender of the Templars. See also Hallam, *Middle Ages*, c. i. note 15.

BAPTISM. Christian baptism is the sacrament by which a person is initiated into the Christian Church. The word is derived from the Greek βαπτίζω, the frequentative form of βάπτω, to dip or wash, which is the term used in the New Testament when the sacrament is described. In discussing what is meant by baptism, three things have to be inquired into—(1) the origin of the rite, (2) its meaning, or the doctrine of baptism, and (3) the form of the rite itself.

I. *The Origin of Baptism.*—Christian theologians do not require to go farther back than to the New Testament, for there, in the record of our Lord's life, and in the writings of His apostles, they find all that is required to form a basis for their doctrines. The principal passages in the New Testament in which baptism is described are as follows:—Matt. xxviii. 18–20; Mark xvi. 16; John iii. 26; Acts ii. 38, x. 44, *ff.*, viii. 16, xix. 1, *ff.*, xxii. 16; Rom. vi. 4; 1 Cor. i. 14–16, vi. 11; Eph. v. 26; Col. ii. 12; Heb. x. 22, 23, &c. From these texts we learn that baptism is specially connected with the gift of the Holy Spirit, with the forgiveness of sins, with our being buried with Christ; and we are also taught by whom baptism is to be administered, and who are the proper partakers in the ordinance. It is from a due arrangement and comparison of the conceptions in these texts that a doctrine of baptism has been formed. But while theologians do not require to go beyond the New Testament for the origin and meaning of baptism, historical investigation cannot help trying to trace analogies to the rite in Old Testament and even in Pagan history. In the New Testament itself there are two distinct kinds of baptism spoken of—the baptism of John and Christian baptism. Treatises on Jewish antiquities speak of the baptism of proselytes; and St Paul applies the term baptism to describe certain Old Testament events, and we find in use among certain Pagan tribes rites strongly resembling Christian baptism, so far as external ceremonies go. Hence the question arises, What is the relation of Christian baptism to these?

Writers on the antiquities of the Christian church were accustomed to find the source of Christian baptism in the baptism of John, and to assert that John's baptism was simply a universal and symbolical use of the well-known ceremony of the baptism of proselytes, and they connected this Jewish rite with Old Testament and even with Pagan lustrations. But this mode of explanation must now be abandoned. It is very difficult to show any real connection between the baptism of John and Christian baptism further than the general relation which all the actions of the forerunner must have had to those of the Messiah. We know very little about the baptism of John, and all attempts to describe it minutely are founded either upon conjecture or upon its identity with the baptism of proselytes. Was John's baptism an initiation, and if so, initiation into what? Did Christ baptize in His lifetime, or did Christian baptism properly begin after Christ's death, and after the mission of the Holy Ghost? What was the formula of John's baptism, and was there any change or growth in the formula of Christian baptism? (The Tübingen School, for example, think that the formula in Acts ii. is much earlier than the complete and more developed one in Matt. xxviii. 19.) All these questions require to be answered with much more precision than the present state of our information admits of, before we can define the precise relation subsisting between the baptism of John and the baptism of Christ.

The connection between the baptism of John and the Jewish baptism of proselytes, of which a great deal has been made, is also founded on assumptions which cannot be proved. This very plausible theory first assumes that proselytes were baptized from an early time in the Jewish Church, although the Old Testament tells us nothing about

it, and then supposes that John simply made use of this ordinary Jewish rite for the purpose of declaring symbolically that the whole Jewish nation were disfranchised, and had to be re-admitted into the spiritual Israel by means of the same ceremony which gave entrance to members of heathen nations. But the subject of the baptism of proselytes is one of the most hopelessly obscure in the whole round of Jewish antiquities, and can never be safely assumed in any argument; and the general results of investigation seem to prove that the baptism of proselytes was not one of the Jewish ceremonies until long after the coming of Christ, while there is much to suggest that this Jewish rite owes its origin to Christian baptism. Others again, as Steitz, find the historical basis of baptism in the lustrations or sprinklings with water so often mentioned in the Old Testament, in such symbolical acts as Naaman's bathing in the Jordan, and in various prophecies where purification from sin is denoted by sprinkling, *e.g.*, Ezek. xxxvi. 25–30, Zech. xiii. 1, &c.; but such anticipations can scarcely be called the historical origin of the rite. Many modern writers connect baptism with certain Pagan rites, and point to the lustrations in use in religious initiation among the Egyptians, Persians, and especially the Hindus, but very little can be made of such far-fetched analogies. Perhaps the most curious instance of this kind is to be found in the double baptism,—the one Pagan and civil, and the other religious and Christian,—which existed side by side with each other in Norway and Iceland. The Pagan rite was called "ansa vatri," while the name for Christian baptism was "skéro." The Pagan rite was much older than the introduction of Christianity, and was connected with the savage custom of exposing infants who were not to be brought up. The newly-born infant was presented to the father, who was to decide whether the child was to be reared or not; if he decided to rear it, then water was poured over the child and the father gave it a name; if it was to be exposed, then the ceremony was not gone through. The point to be observed is that, if the child was exposed by any one after the ceremony had been gone through, it was a case of murder, whereas it was not thought a crime if the child was made away with before water had been poured over it and it had been named. The analogy lies in the use of water, the bestowal of the name, and the entrance into civil life through the rite.

II. *The Doctrine of Baptism.*—Among the Greek Fathers, for it is there we must look for the beginning of the doctrine, baptism was called by various names, all of which referred to the spiritual effects which were supposed to accompany the rite. For example, a common term for baptism was Παλιγγενεσία, or *regeneration*—for every Christian was supposed to be born again by the waters of baptism. "We fishes," says Tertullian, "are born in water, conformable to the name of our Lord Jesus Christ,—ἰχθύς." (Ἰησοῦς Χριστὸς, Θεοῦ Υἱὸς, Σωτήρ = ἰχθύς.) It was also called φωτισμός, or *illumination; mysterium; signaculum*, or seal of the Lord; *character Dominicus; μύησις* or μυσταγωγία, the initiation; ἐφοδίον, or viaticum, from its being administered to departing persons; *sacerdotium laici*, or the lay priesthood, because allowed, in cases of necessity, to be conferred by laymen; the *great circumcision*, because it was held to succeed in the room of circumcision; δῶρον and χάρισμα κυρίου, the *gift of the Lord*, because it had Christ for its author, and not man; sometimes by way of eminence simply δῶρον; τελείωσις and τελετή, the *consecration* and *consummation*, because it gave men the perfection of Christians, and a right to partake of τὸ τέλειον, the Lord's Supper. In studying the statements made by the early Fathers upon baptism, we find not so much a distinct and definite doctrine as gropings toward a doctrine, and it is not until we come to St Augustine that we can find any strict and scientific theory of the nature and effects of the sacrament. The earlier theologians sometimes make statements which imply the most extreme view of the magical effects of the sacrament, and at other times explain its results in a purely ethical way. Thus, for example, Hermas says,—"Our life is sanctified by water;" while Tertullian expressly declares,—"Anima non lavatione sed responsione sancitur." It should never be forgotten that the abundant use of metaphorical language by the Greek Fathers, and the want of anything like a strictly theological terminology, prevent our finding anything like the precise doctrinal statements which became familiar in the Western Church; while the prevalence of curious Greek physical speculations, which taught the creative power of water, mingled with and distorted the ideas about the effects of the water in baptism. It was St Augustine, the great theologian of the Western Church, who first gave expression to exact dogmatic statements about the nature and meaning of baptism. The real difficulty to be explained was the connection between the outward rite and the inward spiritual change; or to put it more precisely, the relation between the water used and the Holy Spirit who can alone regenerate. The Greek theologians had shirked rather than faced the difficulty, and used terms at one time exaggerating the magical value of the element, at another insisting on the purely ethical and spiritual nature of the rite; but they never attempted to show in what precise relation the external rite stood to the inward change of heart. It is true that one or two theologians had almost anticipated Augustine's view, but the anticipation was more apparent than real, for the theology of the Greek Church in this, as in most other doctrines, is greatly hampered by the mystical tendency to represent regeneration and kindred doctrines much more as a species of chemical change of nature than as a change in the relations of the will. Augustine insisted strongly on the distinction between the sacrament itself and what he called the "res sacramenti," between the inward and spiritual and the outward and material, and by doing so Augustine became the founder of both the modern Roman Catholic and the modern orthodox Protestant views. Apart from certain modifying influences, it would not be difficult for the orthodox Protestant to subscribe to most of Augustine's views upon baptism, for he insists strongly on the uselessness of the external sign without the inward blessing of the Spirit. But in this doctrine, as in most others, Augustine's doctrine of the Church so interfered as to make practically inoperative his more spiritual views of baptism. The Church, Augustine thought, was the body of Christ, and that in a peculiarly external and physical way, and just as the soul of man cannot, so far as we know, exert any influence save upon and through the body, so the Spirit of Christ dispenses His gracious and regenerating influences only through the body of Christ, *i.e.*, the Church. But the Church, Augustine thought, was no invisible spiritual communion. It was the visible kingdom of God, the visible "civitas Dei in peregrinatione per terras," and so entrance into the Church, and the right and possibility of participating in the spiritual benefits which members of the Church can alone enjoy was only possible by means of a visible entrance into this visible kingdom. Thus while Augustine in theory always laid greatest stress upon the work of the Holy Spirit and upon the spiritual side of baptism, he practically gave the impulse to that view of the sacrament which made the external rite of primary importance. It was the Holy Spirit who alone imparted spiritual gifts to the children of God. But the one way by which the benefits of this Spirit could be shared was in the first place through baptism. Baptism was thought to be necessary to salvation, and all who were unbaptized were unsaved. In this way Augustine, while

recognizing the spiritual nature of the sacrament, held views about the importance of the rite which were as strong as those of any Greek theologian who had mingled confusedly in his mind Christian doctrines and the maxims of Pagan philosophy about the creative power of the element of water. Of course such a doctrine of the importance of the baptism with water had to be modified to some extent. There were cases of Christian martyrs who had never been baptized, and yet had confessed Christ and died to confess Him: for their sakes the idea of a baptism of blood was brought forward; they were baptized not with water, but in their own blood. And the same desire to widen the circle of the baptized led the way to the recognition of the baptism of heretics, laymen, and nurses. It was the Augustinian doctrine of baptism which was developed by the Schoolmen, and which now is the substance of modern Roman Catholic teaching. The Schoolmen, whose whole theology was dominated by the Augustinian conception of the Church, simply took over and made somewhat more mechanical and less spiritual Augustine's doctrine. They were enabled to give the doctrine a more precise and definite shape by accommodating it to the terms of the Aristotelian philosophy. They began by distinguishing between the matter and the form of baptism. Had Augustine had this distinction before him he would probably have called the water the matter, and the action of the Holy Spirit the form which verified and gave shape to the matter; but the whole idea of the Schoolmen was much more mechanical, the magical idea of the sacrament came much more into prominence, and the spiritual and ethical fell much more into the background, and with them, while water was the *materia sacramenti*, the *forma sacramenti* was the words of the rite,—"I baptize thee," &c., &c. Thus insensibly the distinction between the external rite and the work of the Holy Spirit, which Augustine had clearly before him in theory at least, was driven back into its original obscurity, and while it was always held theoretically that the grace conferred in baptism was conferred by the Holy Spirit, still the action of the Spirit was so inseparably connected with the mechanical performance of the rite, that the external ceremony was held to be full warrant for the inward spiritual presence and power, and it was held that in baptism grace was conferred *ex opere operato*. The actual benefits which were supposed to come in this way were, freedom from original sin and forgiveness of it and all actual sins committed up to the time of baptism, and the implanting of the new spiritual life—a life which could only be slain by a deadly sin. The Scholastic doctrine of baptism is the doctrine of the Roman Catholic Church, and the restatements made by Mohler on the one hand, and Jesuit theologians on the other, do not do more than give a poetical colouring to the doctrine, or bring out more thoroughly the magical and mechanical nature of the rite.

The Protestant doctrine of baptism, like the Scholastic or Roman Catholic, is to be traced back to Augustine and his distinction between the sign and the thing signified, and may be looked at as a legitimate development of the Augustinian doctrine, just as that must be considered to be an advance on the doctrine of the early Church Fathers. The early Fathers had confused the sign with the thing signified,—the water with the action of the Holy Spirit,—and could only mark their half-conscious recognition of the distinction by an alternating series of strong statements made now on the one side and now on the other. Augustine distinguished the two with great clearness, but connected them in an *external* way by means of his conception of the visible Church and of baptism as the door leading into it, and this led his followers to pay exclusive attention to the external side, until the thing signified became lost in the sign. The Protestant theologians connected the two in an *internal* way by means of the spiritual conception of faith, and so were able always to keep the sign in due subordination to the thing signified. It is faith—not faith in the sense of imperfect knowledge, or assent to intellectual propositions, but faith in the sense of personal trust in a personal Saviour, or "fiducia," as the 17th century theologians called it—which so connects the water with the presence and power of the Spirit that the one is the means which the other uses to impart His spiritual grace. In this way baptism is looked upon as one of the means of grace, and grace is imparted through it as through the other means—the Lord's Supper, the Word of God, prayer, &c. Just as the dead letters and sounds of the Word of God are but the signs of the presence and power of His Spirit, and become at His touch the living revelation of the Lord, so in baptism, the outward rite, worthless in itself, becomes the sign and pledge of the presence and power of the Spirit of God; and as, in the case of the Word of God, it is faith or "fiducia" that on the human side connects the external signs with the inward power of the Spirit, so, in baptism, it is the same faith which unites the water and the Spirit. So far all orthodox Protestants are agreed, but in order to show the historical evolution of the doctrine, it is necessary to notice in a sentence the difference between the Lutheran and the Calvinist doctrines. Luther's own doctrine of baptism changed very much: in the second stage—the stage represented by the tract, *De Babyl. Capt. Eccl.*—it is not different, in germ at least, from the Calvinist view; but he afterwards drew back and adopted views much nearer to the Scholastic theory. He was evidently afraid that, if he went too far from the Scholastic doctrine, and insisted too strongly on the importance of faith, he might be led on to reject the baptism of infants; and his later theories are a recoil from that. The question which Luther had to face and answer here was, What is meant by faith, the faith which connects the symbol with the reality, and so appropriates the gifts of God's grace in the sacrament? Is it a faith which begins and ends in the individual act of faith at work in the person that is baptized? or is it a much wider thing with a more universal significance? Luther did not face this question thoroughly, but his recoil from the Reformed theory of baptism seems to show that he would have taken the former answer. Nor did Calvin face the question; but his doctrine of baptism implies that he would have taken the latter answer. The faith which a man has in Christ, the faith which appropriates, is not the individual's only, but extends far beyond him and his small circle. It is awakened by the Holy Spirit, it comes into being within the sphere of God's saving purpose. Its very existence indicates a *solidarité* between the individual believer and the whole Church of God. Hence on the Reformed doctrine, while faith is essential to the right appropriation of the blessing in the rite, there is no need for thoroughly developed faith in those who are baptized. If they are infants, then they are baptized because of the faith of their parents or near relations, or of the congregation before whom the baptism is performed; only those who are the sponsors for the child bind themselves before God to train up the child to know that it has been baptized, and to appropriate in conscious individual faith the benefits of the ordinance. Such is the Reformed theory of baptism; and it rests upon the ideas of the *solidarité* of believers, of the prior existence of the Church to the individual believers, and of the ethical unity of the Church. On the other hand, those who hold that the Church is simply the sum of individual men and women, and that it is increased not by the silent widening of the influence of God's saving purpose within mankind, but by individual conversions and by individuals joining the

Church, cannot help regarding infant baptism as a mere mockery. Hence the doctrines of the Anabaptists, Baptists, Mennonites, &c. (see BAPTISTS), who reject infant baptism altogether, and maintain that there can be no valid baptism without the conscious appropriation by an act of faith of the benefits symbolized by the rite. It is to be noticed that the tendency of those who reject infant baptism is to regard the sacrament not so much as a means of grace, but simply as an act symbolical of entrance into the Church, and to approach in this way the views of the Socinians and Remonstrants. Quakers reject baptism altogether along with the sacrament of the Supper.

III. *Baptismal Rites.*—In the Apostolic and immediately post-Apostolic Church, there was no stated time or place for baptism. Philip baptized the Ethiopian eunuch by the roadside, as soon as he had declared his faith. Afterwards, however, Easter, Whitsuntide, and Epiphany were seasons supposed to be specially appropriate for baptism, and the sacrament was not performed at other times save in cases of necessity. Baptism, Tertullian said, had special reference to the death and rising again of our Lord, and also to the mission of the Holy Ghost; and festivals which were connected with these events were specially appropriate for baptism. As soon, too, as churches were built, and congregations formed, baptism became a public act of worship, and was generally performed in baptisteries built adjoining the church. The early Church, like most of the Reformation Churches, condemned private baptism.

In the Apostolic Church the baptismal rite seems to have been a very simple one. "Repent and be baptized, every one of you," was all that Peter thought it necessary to say to those whom he invited to join the Christian Church; but soon after the Apostolic times baptism became a very elaborate ceremonial. No one could be baptized unless he had submitted to a long and elaborate course of instruction as a catechumen; and in order to be made a catechumen a ceremony of some length had to be gone through. The candidate was received into the number of the catechumens by the laying on of hands and prayer; and, in the Western Church, salt was given to him, the *salis datio* being held to be the special *sacramentum catechumenorum.* Catechumens were permitted to attend public worship at first as hearers only; afterwards they were permitted to take part in the responses and genuflections of the audience. From these catechumens the candidates for baptism, called *competentes* or *electi*, were from time to time selected. The baptismal ceremony was a lengthy one. The catechumens were first received, then got their Christian names, then, facing the west, the place of darkness, they renounced the devil and all his works. The priest then exorcised them, by laying his hands upon their heads and breathing into their faces. After the exorcism came the opening of the ears and nose, a ceremony which had special reference to the descent of the Holy Ghost upon Christ in the form of a dove. The catechumens were then anointed with the catechumen oil. (This part of the ceremony was sometimes gone through after baptism, although it is possible that there were two anointings, one before and one after.) The officiating priest then repeated the Creed and the Lord's Prayer, and gave a short explanation of their meaning, and the lengthy ceremony was concluded by the catechumen repeating the Lord's Prayer and the Apostles' Creed. All these ceremonies preceded the special baptismal rite, and commonly occupied more than one day. In the baptismal ceremony the minister first consecrated the water by prayer, and the catechumen was then baptized in the name of the Father, the Son, and the Holy Ghost. The usual mode of performing the ceremony was by immersion. In the case of sick persons (*clinici*) the minister was allowed to baptize by pouring water upon the head or by sprinkling. In the early Church "clinical" baptism, as it was called, was only permitted in cases of necessity, but the practice of baptism by sprinkling gradually came in in spite of the opposition of councils and hostile decrees. The Council of Ravenna, in 1311, was the first council of the Church which legalized baptism by sprinkling, by leaving it to the choice of the officiating minister. The custom was to immerse three times, once at the name of each of the persons in the Trinity, but latterly the threefold immersion was abolished, because it was thought to go against the unity of the Trinity. The words used in baptizing always embodied the formula in the last chapter of St Matthew. But the mode of uttering them varied. In the Western Church the priest uttered the simple formula, but in the Eastern Church the common formula was, *βαπτίζεται ὁ δοῦλος τοῦ θεοῦ ὁ δεῖνα εἰς τὸ ὄνομα τοῦ πατρὸς—'Αμὴν— καὶ τοῦ υἱοῦ—'Αμὴν — καὶ τοῦ ἁγίου πνεύματος—'Αμὴν—νῦν καὶ ἀεὶ εἰς τοὺς αἰῶνας τῶν αἰώνων. 'Αμήν.* After immersion the neophyte partook of milk and honey to show that he was now the recipient of the gifts of God's grace; he was then anointed with oil to show that he was enrolled among the spiritual priesthood, and with the unction was joined the sign of the cross made on the forehead. Then followed the laying on of hands, which latterly, when the episcopate became separate from the presbytery, was done by the bishop, and was the germ of the sacrament of confirmation. In the course of time one or two other symbolical actions were added; the neophyte was clothed in a white garment—(hence Pentecost, which was the principal baptismal festival, was called Whit-sunday)—and a band (chrismale) was put round his head. In the Eastern Church there followed the girding of the loins of the neophyte and the crowning of him with a consecrated corona, significant of his entrance into the royal priesthood; in the Western Church a burning cross was given him. In the various Eastern churches the rites differed somewhat from each other, nor was exact uniformity to be found in the Western Church. It could easily be shown that a great deal of this complex ceremonial took its origin from the introduction of Pagan ceremonies into the Christian worship.

The present form of administering baptism in the Church of Rome is as follows:—When a child is to be baptized, the persons who bring it wait at the door of the church for the priest, who comes thither in his surplice and his purple stole, surrounded by his clerks. He begins by questioning the godfathers, whether they promise in the child's name to live and die in the true Catholic and Apostolic faith; and what name they would give to the child. Then follows an exhortation to the sponsors, after which the priest, calling the child by its name, asks, "What dost thou demand of the Church?" The godfather answers, "Eternal life." The priest proceeds, "If thou art desirous of obtaining eternal life, keep God's commandments,—Thou shalt love the Lord thy God," &c.; after which he breathes three times in the child's face, saying, "Come out of this child, thou evil spirit, and make room for the Holy Ghost." Then he makes the sign of the cross on the child's forehead and breast, saying, "Receive the sign of the cross on thy forehead and in thy heart;" upon which, taking off his cap, he repeats a short prayer, and, laying his hand gently on the child's head, repeats a second prayer; then he blesses some salt, and putting a little of it into the child's mouth, he says, "Receive the salt of wisdom." All this is performed at the church door. Afterwards, the priest, with the godfathers and godmothers, come into the church, and advancing towards the font, repeat the Apostles' Creed and the Lord's Prayer. Arrived at the font, the priest again exorcises the evil spirit, and taking a little of his own spittle, with the thumb of his right hand rubs it on the child's ears and nostrils, repeating as he touches the right

ear, the same word *Ephphatha*, "be thou opened," which our Saviour made use of to the man born deaf and dumb. Lastly, they pull off its swaddling-clothes, or strip it below the shoulders, during which the priest prepares the oil. The sponsors then hold the child directly over the font, observing to turn it due east and west; whereupon the priest asks the child whether he renounces the devil and all his works, and the godfather having answered in the affirmative, the priest anoints the child between the shoulders in the form of a cross; then taking some of the consecrated water, he pours part of it thrice on the child's head, at each perfusion calling on one of the persons of the Holy Trinity. The priest concludes the ceremony of baptism with an exhortation. It may be added that the Roman Church allows midwives, in cases of danger, to baptize a child before the birth is completed. A still-born child thus baptized may be buried in consecrated ground.

With regard to the form of baptism used in the Church of England, we shall only mention one or two of the more material differences between the form as it stood in the first liturgy of King Edward, and that in the English Common Prayer Book at present. First, the form of consecrating the water did not make a part of the office in King Edward's liturgy, as it does in the present, because the water in the font was changed and consecrated but once a month. The form itself likewise was something different from that now used, and was introduced with a short prayer that Jesus Christ, upon whom (when He was baptized) the Holy Ghost came down in the likeness of a dove, would send down the same Holy Spirit, to sanctify the fountain of baptism, which prayer was afterwards left out at the second revision. By King Edward's first book the minister was required to dip the child in the water thrice; first the right side, secondly the left, and lastly the face toward the foot. This triple immersion was a very ancient practice in the Christian Church, and was used in honour of the Holy Trinity,—though some later writers say it was done to represent the death, burial, and resurrection of Christ, together with His three days' continuance in the grave. But afterwards, the Arians persuading the people that the custom denoted a distinct substantiality of the three persons in the Trinity, the orthodox party discontinued it and used only one single immersion.

By the first Common Prayer Book of King Edward, after the child was baptized the godfathers and godmothers were to lay their hands upon him, and the minister was to put on him the white vestment, commonly called the *chrysome*, and to say, "Take this white vesture as a token of the innocency which, by God's grace, in this holy sacrament of baptism, is given unto thee, and for a sign whereby thou art admonished, so long as thou livest, to give thyself to innocence of living, that after this transitory life thou mayest be partaker of the life everlasting." As soon as he had pronounced these words, he was to anoint the infant on the head, saying, "Almighty God, the father of our Lord Jesus Christ, who hath regenerated thee by water and the Holy Ghost, and hath given unto thee remission of all thy sins, may He vouchsafe to anoint thee with the unction of His Holy Spirit, and bring thee to the inheritance of everlasting life."

Baptism of the dead seems to have been founded on the opinion that when men had neglected to receive baptism in their lifetime, some compensation might be made for this default by their receiving it after death, or by another being baptized for them. This practice was chiefly in use among various heretical sects.

Hypothetical Baptism was that administered in certain doubtful cases, with the formula, "If thou art baptized, I do not rebaptize; if thou art not, I baptize thee in the name of the Father," &c.

Solemn Baptism was that conferred at stated seasons. Such in the ancient Church were the Paschal baptism and that at Whitsuntide. This is sometimes also called general baptism.

Lay Baptism we find to have been permitted both by the Common Prayer Book of King Edward, and by that of Queen Elizabeth, when an infant is in immediate danger of death, and a lawful minister cannot be had; but afterwards, in a convocation held in the year 1575, it was unanimously resolved, that even private baptism, in a case of necessity, was only to be administered by a lawful minister. The Scotch Reformed Church also prohibited private baptism by lay persons, but ordained that when any had been thus baptized, the rite was not to be repeated.

The name *baptism* has been applied to certain ceremonies used in giving names to things inanimate. The ancients knew nothing of the custom of giving baptism to inanimate things, such as bells, ships, and the like. The first notice we have of this is in the capitulars of Charles the Great, where it is mentioned with censure; but afterwards it crept by degrees into the Roman offices. Baronius carries its antiquity no higher than the year 968, when the great bell of the church of Lateran was christened by Pope John III. At last it grew to such a height as to form a ground of complaint in the *Centum Gravamina* of the German nation, drawn up at the diet of Nuremberg in 1581, where the ceremony of baptizing a bell, with godfathers, &c., to make it capable of driving away tempests and devils, was declared to be a superstitious practice, contrary to the Christian religion, and a mere seduction of the simple people.

BAPTISTERY (*Baptisterium*, in the Greek Church *φωτιστήριον*) was a hall or chapel in which the catechumens were instructed and the sacrament of baptism administered. It was commonly a circular building, although sometimes it had eight and sometimes twelve sides, and consisted of an ante-room (*προαύλιος οἶκος*) where the catechumens were instructed, and where before baptism they made their confession of faith, and an inner apartment where the sacrament was administered. In the inner apartment the principal object was the baptismal font (*κολυμβήθρα*, or *piscina*), in which those to be baptized were immersed thrice. Three steps led down to the floor of the font, and over it was suspended a golden or silver dove; while on the walls were commonly pictures of the scenes in the life of the Baptist. The font was at first always of stone, but latterly metals were often used. Baptisteries belong to a period of the church when great numbers of adult catechumens were baptized, and when immersion was the rule. We find little or no trace of them before Constantine made Christianity the state religion, *i.e.*, before the 4th century; and as early as the 6th century the baptismal font was built in the porch of the church and then in the church itself. After the 9th century few baptisteries were built, the most noteworthy of later date being those at Pisa, Florence, Padua, Lucca, and Parma. Some of the older baptisteries were very large, so large that we hear of councils and synods being held in them. It was necessary to make them large, because in the early church it was customary for the bishop to baptize all the catechumens in his diocese (and so baptisteries are commonly found attached to the cathedral and not to the parish churches), and also because the rite was performed only thrice in the year. (See Baptism.) During the months when there were no

baptisms the baptistery doors were sealed with the bishop's seal. Baptisteries, we find from the records of early councils, were first built and used to correct the evils arising from the practice of private baptism. As soon as Christianity made such progress that infant baptism became the rule, and as soon as immersion gave place to sprinkling, the ancient baptisteries were no longer necessary. They are still in general use, however, in Florence and Pisa. The name *baptistery* is sometimes also given to a kind of chapel in a large church, which served the same purpose. (*Cf.* Hefele's *Concilien, passim;* Du Cange, *Glossary*, article "Baptisterium;" Eusebius, *Hist. Eccl.* x. 4; Bingham's *Antiquities of the Christian Church*, book xi.)

BAPTISTS, a denomination of Christians, distinguished, as their name imports, from other denominations by the views they hold respecting the ordinance of baptism.

The early history of the Baptists, both in this country and on the Continent, is very obscure. In the great awakening of religious thought and feeling which characterized the beginning of the 16th century, it was inevitable that amongst those who burst the fetters which bound them to the see of Rome some should be willing to retain as much of the ancient doctrine and practice as they could with a safe conscience, whilst others, rejoicing in their new-found liberty, would desire to cast aside every remnant of what they regarded as superstition, and to advance as far as possible in the path of what they deemed Christian liberty; nor is it at all to be wondered at that strange and wild theories on matters even remotely connected with religion should spring into life. But amidst all the diversities of opinion that existed, it was constantly held by Protestants that "holy Scripture containeth all things necessary to salvation, so that whatsoever is neither read therein nor may be proved thereby, although it be sometime received of the faithful as godly and profitable for an order and comeliness, yet no man ought to be constrained to believe it as an article of faith or repute it requisite to the necessity of salvation" (Articles of King Edward VI.) We must not be surprised that the right of private judgment, which is involved in the principle thus broadly laid down, was nevertheless far from being conceded to the extent that was desired by those who departed farthest from the Church of Rome. In fact, each separate section of Protestants claimed for itself to stand on the ground of holy Scripture, and was prepared to resist alike the tyranny of Rome and what it considered the licence of other bodies of Protestants. Thus it happened that the Baptists, or, as their opponents called them, the Anabaptists (or, as Zwingli names them, Catabaptists), were strenuously opposed by all other sections of the Christian Church, and it was regarded by almost all the early reformers to be the duty of the civil magistrate to punish them with fine and imprisonment, and even with death. There was, no doubt, some justification for this severity in the fact that the fanaticism which burst forth in the early times of the Reformation frequently led to insurrection and revolt, and in particular that the leader of the "peasant war" in Saxony, Thomas Münzer, and probably many of his followers, were "Anabaptists." One result of this severity is, that the records of the early history of the Anabaptists both on the Continent and in this country are very few and meagre. Almost all that is currently known of them comes to us from their opponents. There is, however, much valuable information, together with detailed accounts of their sufferings, in the Dutch Martyrology of Van Braght, himself a Baptist, which bears the title *Martelaers Spiegel der Doops-gesinde* (2d ed. fol., 1685), an English translation of the latter half of which was published in 2 vols. 8vo, Lond. 1850-53, edited by Dr Underhill, now secretary of the Baptist Missionary Society. Probably the earliest confession of faith of any Baptist community is that given by Zwingli in the second part of his *Elenchus contra Catabaptistas*, published in 1527. Zwingli professes to give it entire, translating it, as he says, *ad verbum* into Latin. He upbraids his opponents with not having published these articles, but declares that there is scarcely any one of them that has not a written (*descriptum*) copy of these laws which have been so well concealed. The articles are in all seven. The first, which we give in full, relates to baptism:—

"Baptism ought to be given to all who have been taught repentance and change of life, and who in truth believe that through Christ their sins are blotted out (*abolita*), and the sins of all who are willing (*volunt*) to walk in the resurrection of Jesus Christ, and who are willing to be buried with him into death, that they may rise again with him. To all, therefore, who in this manner seek baptism, and of themselves ask us, we will give it. By this rule are excluded all baptisms of infants, the great abomination of the Roman pontiff. For this article we have the testimony and strength of Scripture, we have also the practice of the apostles; which things we simply and also stedfastly will observe, for we are assured of them."

The second article relates to withdrawment (*abstentio*) or excommunication, and declares that all who have given themselves to the Lord and have been baptized into the one body of Christ should, if they lapse or fall into sin, be excommunicated. The third article relates to the breaking of bread; in this it is declared that they who break the one bread in commemoration of the broken body of Christ, and drink of the one cup in commemoration of His blood poured out, must first be united together into the one body of Christ, that is, into the church of God. The fourth article asserts the duty of separation from the world and its abominations, amongst which are included all papistical and semi-papistical works. The fifth relates to pastors of the church. They assert that the pastor should be some one of the flock who has a good report from those who are without. "His office is to read, admonish, teach, learn, exhort, correct, or excommunicate in the church, and to preside well over all the brethren and sisters both in prayer and in the breaking of bread; and in all things that relate to the body of Christ, to watch that it may be established and increased so that the name of God may by us be glorified and praised, and that the mouth of blasphemers may be stopped." The sixth article relates to the power of the sword. "The sword," they say, "is the ordinance of God outside the perfection of Christ, by which the bad is punished and slain and the good is defended." They further declare that a Christian ought not to decide or give sentence in secular matters, and that he ought not to exercise the office of magistrate. The seventh article relates to oaths, which they declare are forbidden by Christ.

However much we may differ from the points maintained in these articles, we cannot but be astonished at the vehemence with which they were opposed, and the epithets of abuse which were heaped upon the unfortunate sect that maintained them. Zwingli, through whom they come down to us, and who gives them, as he says, that the world may see that they are "fanatical, stolid, audacious, impious," can scarcely be acquitted of unfairness in joining together two of them,—the fourth and fifth,—thus making the article treat "of the avoiding of abominable pastors in the church" (*Super devitatione abominabilium pastorum in Ecclesia*), though there is nothing about pastors in the fourth article, and nothing about abominations in the fifth, and though in a marginal note he himself explains that the first two copies that were sent him read as he does, but the other copies make two articles, as in fact they evidently are. To us at the present day it appears not merely strange but shocking, that the Protestant Council of Zurich, which had scarcely won its own liberty, and was still in dread of the persecution of the Romanists, should pass a decree

ordering, as Zwingli himself reports, that any person who administered anabaptism should be drowned; and still more shocking that, at the time when Zwingli wrote, this cruel decree should have been carried into effect against one of the leaders of the Anabaptists, Felix Mantz, who had himself been associated with Zwingli, not only as a student, but also at the commencement of the work of Reformation. No doubt the wild fanaticism of some of the opponents of infant baptism seemed to the Reformers to justify their severity. In 1537 Menno Simonis joined himself to the Anabaptists and became their leader. His moderation and piety, according to Mosheim, held in check the turbulence of the more fanatical amongst them. He died in 1561, after a life passed amidst continual dangers and conflicts. His name remains as the designation of the Mennonites, who eventually settled in the Netherlands under the protection of William the Silent, Prince of Orange.

Of the introduction of Baptist views into England we have no certain knowledge. Fox relates that "the registers of London make mention of certain Dutchmen counted for Anabaptists, of whom ten were put to death in sundry places in the realm, *anno* 1535; other ten repented and were saved." In 1536 King Henry VIII., as "in earth supreme head of the Church of England," issued a proclamation together with articles concerning faith agreed upon by Convocation, in which the clergy are told to instruct the people that they ought to repute and take "the Anabaptists' opinions for detestable heresies and to be utterly condemned." The document is given *in extenso* by Fuller, who further tells us from Stow's *Chronicles* that, in the year 1538, "four Anabaptists, three men and one woman, all Dutch, bare faggots at Paul's Cross, and three days after a man and woman of their sect was burnt in Smithfield." In the reign of Edward VI., after the return of the exiles from Zurich, Hooper writes to his friend Bullinger in 1549, that he reads "a public lecture twice in the day to so numerous an audience that the church cannot contain them," and adds, "the Anabaptists flock (*confluunt*) to the place and give me much trouble." It would seem that at this time they were united together in communities separate from the Established Church. Latimer, in 1552, speaks of them as segregating themselves from the company of other men. In Philpott's sixth examination in 1555 we are told that Lord Riche said to him, "All heretics do boast of the Spirit of God, and every one would have a church by himself, as Joan of Kent and the Anabaptists." Philpott was imprisoned soon after Mary's accession in 1553; and it is very pleasing to find, amidst the records of intense bitterness and rancour which characterized these times, and with which Romanist and Protestant alike assailed the persecuted Baptists, a letter of Philpott's, to a friend of his, "prisoner the same time in Newgate," who held Baptist opinions. His friend had written to ask his judgment concerning the baptism of infants. Philpott in a long reply, whilst maintaining the obligation of infant baptism, yet addresses his correspondent as, "dear brother, saint, and fellow-prisoner for the truth of Christ's gospel;" and at the close of his argument he says, "I beseech thee, dear brother in the gospel, follow the steps of the faith of the glorious martyrs in the primitive church, and of such as at this day follow the same." During the whole of the 16th century, and through the greater part of the 17th, whatever changes took place in the state church, the Baptists in England, together with other dissenters, continued to suffer persecution. Archbishop Sandys, about the year 1576, says: "It is the property of froward sectaries," amongst whom he classes Anabaptists, "whose inventions cannot abide the light, to make obscure conventicles;" and though he admits that "when the gospel is persecuted, secret congregations are allowed," he declares that as the gospel, "strengthened with the civil hand," is now publicly and sincerely preached, "such stray sheep as will not of their own accord assemble themselves to serve the Lord in the midst of this holy congregation, may lawfully and in reason ought to be constrained thereunto." There is no doubt that a large number of the Baptists in England at this time came from Holland, but there is little reason to think that Fuller is correct when, after speaking of certain Dutch Anabaptists being seized in 1575, some of whom were banished and two burnt at Smithfield, he adds, "we are glad that English as yet were free from that infection."

About the beginning of the 17th century the severe laws against the Puritans led many dissenters to emigrate to Holland. Some of these were Baptists, and an English Baptist Church was formed in Amsterdam about the year 1609 In 1611 this church published "a declaration of faith of English people remaining at Amsterdam in Holland." The article relating to baptism is as follows:—"That every church is to receive in all their members by baptism upon the confession of their faith and sins, wrought by the preaching of the gospel according to the primitive institution and practice. And therefore churches constituted after any other manner, or of any other persons, are not according to Christ's testament. That baptism or washing with water is the outward manifestation of dying unto sin and walking in newness of life; and therefore in no wise appertaineth to infants." They hold "that no church ought to challenge any prerogative over any other;" "that magistracy is a holy ordinance of God;" "that it is lawful in a just cause for the deciding of strife to take an oath by the name of the Lord."

The last execution for heresy in England by burning alive took place at Lichfield, April 11, 1612. The condemned person, Edward Wightman, was a Baptist. Much uncertainty rests on the history of the Baptists during the next twenty years. If would seem that many members of the Brownist or Independent denomination held Baptist views. An independent congregation in London, gathered in the year 1616, included several such persons, and as the church was larger than could conveniently meet together in times of persecution, they agreed to allow these persons to constitute a distinct church, which was formed on the 12th September 1633; and upon this most, if not all, the members of the new church were baptized. Another Baptist church was formed in London in 1639. These churches were "Particular" or Calvinistic Baptists. The church formed in 1609 at Amsterdam held Arminian views. In 1644 a Confession of Faith was published in the names of seven churches in London "commonly (though falsely) called Anabaptist," in which were included the two churches just mentioned. The article on baptism is as follows:—"That baptism is an ordinance of the New Testament given by Christ to be dispensed only upon persons professing faith, or that are disciples, or taught, who, upon a profession of faith, ought to be baptized." "The way and manner of dispensing this ordinance the Scripture holds out to be dipping or plunging the whole body under water." They further declare that "a civil magistracy is an ordinance of God," which they are bound to obey. How well they understood the distinction between the rights of conscience and the rights of the civil magistrate is shown with remarkable clearness:—

"We believe," they say, "that in all those civil laws which have been acted by them [the supreme magistracy], or for the present are or shall be ordained, we are bound to yield subjection and obedience unto in the Lord, as conceiving ourselves bound to defend both the persons of those thus chosen, and all civil laws made by them, with our persons, liberties, and estates, with all that is called ours, although we should suffer never so much from them in not actively

submitting to some ecclesiastical laws, which might be conceived by them to be their duties to establish, which we for the present could not see, nor our consciences could submit unto; yet are we bound to yield our persons to their pleasures."

They go on to speak of the breathing time which they have had of late, and their hope that God would, as they say, "incline the magistrates' hearts so for to tender our consciences as that we might be protected by them from wrong, injury, oppression, and molestation;" and then they proceed: "But if God withhold the magistrates' allowance and furtherance herein, yet we must, notwithstanding, proceed together in Christian communion, not daring to give place to suspend our practice, but to walk in obedience to Christ in the profession and holding forth this faith before mentioned, even in the midst of all trials and afflictions, not accounting our goods, lands, wives, children, fathers, mothers, brethren, sisters, yea, and our own lives, dear unto us, so that we may finish our course with joy; remembering always that we ought to obey God rather than men." They end their confession thus: "If any take this that we have said to be heresy, then do we with the apostle freely confess, that after the way which they call heresy worship we the God of our fathers, believing all things which are written in the Law and in the Prophets and Apostles, desiring from our souls to disclaim all heresies and opinions which are not after Christ, and to be stedfast, unmovable, always abounding in the work of the Lord, as knowing our labour shall not be in vain in the Lord." The breathing time of which they speak was not of long continuance. Soon after the Restoration (1660) the meetings of Nonconformists were continually disturbed by the constables, and their preachers were carried before the magistrates and fined or imprisoned. One instance of these persecutions will, perhaps, be more impressive than any general statements. In the records of one of the churches at Bristol still existing, and having, now and for perhaps nearly two centuries, their place of meeting in Broadmead, but at this time meeting in divers places, we find this remark: "On the 29th of November 1685 our pastor, Brother Fownes, died in Gloucester jail, having been kept there for two years and about nine months a prisoner, unjustly and maliciously, for the testimony of Jesus and preaching the gospel. He was a man of great learning, of a sound judgment, an able preacher, having great knowledge in divinity, law, physic, &c.; a bold and patient sufferer for the Lord Jesus and the gospel he preached." From the same records we learn that on the 25th March 1683, whilst Mr Fownes was preaching in the wood where they were accustomed secretly to meet, they were surrounded by horse and foot. Mr Fownes was taken and committed "to Gloucester jail for six months on the Oxford Act." The record adds, "the text Brother Fownes had been preaching from was 2 Tim. ii. 9." There could scarcely have been found a more appropriate text for his last sermon to the congregation,—"Wherein I suffer trouble as an evil doer even unto bonds, but the word of God is not bound."

With the Revolution of 1688, and the passing of the Act of Toleration in 1689, the history of the persecution of Baptists, as well as of other Protestant dissenters, ends. The removal of the remaining disabilities, such as those imposed by the Test and Corporation Acts repealed in 1828, has no special bearing on Baptists more than on other Nonconformists. The ministers of the "three denominations of dissenters,"—Presbyterians, Independents, and Baptists,—resident in London and the neighbourhood, had the privilege accorded to them of presenting on proper occasions an address to the sovereign in state, a privilege which they still enjoy.

The Baptists were early divided into two sections,—those who in accordance with Arminian views held the doctrine of "General Redemption," and those who, agreeing with the Calvinistic theory, held the doctrine of "Particular Redemption;" and hence they assumed respectively the names of General Baptists and Particular Baptists. In the last century many of the General Baptists had gradually adopted the Arian, or, perhaps, the Socinian theory; whilst, on the other hand, the Calvinism of the Particular Baptists had in many of the churches become more rigid, and approached or actually became Antinomianism. In 1770 the orthodox portion of the General Baptists formed themselves into a separate association, under the name of the General Baptist New Connection, since which time the "Old Connection" has gradually merged into the Unitarian denomination. Somewhat later many of the Particular Baptists churches became more moderate in their Calvinism, a result largely attributable to the writings of Andrew Fuller. Up to this time a great majority of the Baptists admitted none either to membership or communion who were not baptized, the principal exception being the churches in Bedfordshire and Hertfordshire, founded or influenced by Bunyan, who maintained that difference of opinion in respect to water baptism was no bar to communion. At the beginning of the present century this question was the occasion of great and long-continued discussion, in which the celebrated Robert Hall took a principal part. The practice of mixed communion gradually spread in the denomination. Still more recently many Baptist churches have considered it right to admit to full membership persons professing faith in Christ, who do not agree with them respecting the ordinance of baptism. Such churches justify their practice on the ground that they ought to grant to all their fellow Christians the same right of private judgment as they claim for themselves. It may not be out of place here to correct the mistake, which is by no means uncommon, that the terms Particular and General as applied to Baptist congregations are intended to express this difference in their practice, whereas these terms relate, as has been already said, to the difference in their doctrinal views. The difference now under consideration is expressed by the terms "strict" and "open," according as communion (or membership) is or is not confined to persons who, according to their view, are baptized.

The Baptists early felt the necessity of providing an educated ministry for their congregations. Some of their leading pastors had been educated in one or other of the English Universities. Others had by their own efforts obtained a large amount of learning, amongst whom Dr John Gill was eminent for his knowledge of Hebrew, as shown in his *Exposition of the Holy Scriptures*, a work in 9 vols. folio, 1746-66. Mr Edward Terrill, from whose *Records* we have already quoted, and who died in 1685, left a considerable part of his estate for the instruction of young men for the ministry, under the superintendence of the pastor of the church now meeting in Broadmead, Bristol, of which he was a member. Other bequests for the same purpose were made, and from the year 1720 the Baptist Academy, as it was then called, received young men as students for the ministry among the Baptists. Fifty years later, in 1770, a society, called the Bristol Education Society, was formed to enlarge this academy; and it was still further enlarged by the erection of the present Bristol Baptist College about the year 1811. In the North of England a similar Education Society was formed in 1804 at Bradford, Yorkshire, which has since been removed to Rawdon near Leeds. In the metropolis a college was formed in 1810 at Stepney, and was removed to Regent's Park in 1856. The Pastors' College in connection with the Metropolitan Tabernacle was instituted in 1856. Besides these, the General Baptists have maintained a college since 1797, which at present is carried on at Chil-

well, near Nottingham. A theological institution, intended to promote the views of the "Strict" Baptists, has lately (1866) been established at Manchester. There is also a Baptist theological institution in Scotland, and there are three colleges in Wales. The total number of students in these institutions may be reckoned to be about 200.

The Baptists were the first denomination of British Christians that undertook the work of missions to the heathen, which has become so prominent a feature in the religious activity of the present century. As early as the year 1784, the Northamptonshire Association of Baptist churches resolved to recommend that the first Monday of every month should be set apart for prayer for the spread of the gospel, a practice which has since, as a German writer remarks, extended over all Protestant Christendom, and we may add over all Protestant Missions. Six years later, in 1792, the Baptist Missionary Society was formed at Kettering in Northamptonshire, after a sermon on Isaiah lii. 2, 3, preached by the afterwards celebrated William Carey, the prime mover in the work, in which he urged two points: "Expect great things from God; attempt great things for God." In the course of the following year Carey sailed for India, where he was joined a few years later by Marshman and Ward, and the mission was established at Serampore. The great work of Dr Carey's life was the translation of the Bible into the various languages and dialects of India. The society's operations are now carried on, not only in the East, but in the West Indies, Africa, and Europe. In 1873 there were employed 87 European missionaries and 229 native pastors and evangelists, at 423 stations,—the total number of members of churches being 32,444. The funds of the society amounted to upwards of £40,000, exclusive of the amount raised at mission stations. In 1816 the General Baptists established a missionary society, the operations of which are confined to India. It employs 16 missionaries, male and female, and 16 native preachers, and has an annual income of £14,000.

In regard to church government, the Baptists agree with the Independents that each separate church is complete in itself, and has, therefore, power to choose its own ministers, and to make such regulations as it deems to be most in accordance with the purpose of its existence, that is, the advancement of the religion of Christ. A comparatively small section of the denomination maintain that a "plurality of elders" or pastors is required for the complete organization of every separate church. This is the distinctive peculiarity of those churches in Scotland and the north of England which are known as *Scotch Baptists*. The largest church of this section, consisting at present of 484 members, originated in Edinburgh in 1765, before which date only one Baptist church that of Keiss in Caithness, formed about 1750 appears to have existed in Scotland. The greater number of the churches are united in associations voluntarily formed, all of them determined by geographical limits except the General Baptist Association, which includes all the churches connected with that body. The associations, as well as the churches not in connection with them, are united together in the Baptist Union of Great Britain and Ireland, formed in 1813. This union, however, exerts no authoritative action over the separate churches. One important part of the work of the union is the collection of information in which all the churches are interested. According to the *Baptist Handbook* for the present year (1875), there are in the United Kingdom—Baptist churches, 2612; places of worship, 3321; pastors, 1916; members, 254,998.

Some of the English settlers in all parts of the world have carried with them the principles and practice of the Baptists. The introduction of Baptist views in America was due to Roger Williams, who emigrated to Boston, Massachusetts, in 1630. Driven from Massachusetts on account of his denying the power of the civil magistrate in matters of religion, he formed a settlement and founded a state in Rhode Island, and having become a Baptist he formed, in 1639, the first Baptist church in America, of which he was also for a short time the pastor. It is impossible here to trace the history of the Baptists in the United States. In 1873 there are reported—churches, 20,520; ministers, 12,589; members, 1,633,939. The great majority of the churches practise "strict" communion. Their missionary society is large and successful, and perhaps is best known in this country through the life of devoted labour of Dr Judson in Burmah. There are many Baptist churches also throughout British America. In the more recent colonies of Australia and New Zealand a large number of Baptist churches have been formed during the last twenty-five years, and have been principally supplied with ministers from England. (F. W. G.)

BAR, a town of Russian Poland, in the government of Podolia, 50 miles N.E. of Kaminetz. It is situated on the River Rov, an affluent of the Bug, and was formerly called by that name itself. Its present designation was bestowed in memory of Bari in Italy, by Bona Sforza, the consort of Sigismund I. of Poland, who had rebuilt the town after its destruction in 1452 by the Tatars. From 1672 to 1699 it remained in possession of the Turks. In 1678 a conspiracy of the Polish nobles, Pulaski, Krasinski, and others, against the Russians was formed in the town, which was shortly after taken by storm, but did not become finally united to Russia till the partition of 1793. Eleven fairs are held every year, but the trade of the place is not very great. Population, 8077.

BAR-HEBRÆUS. See ABULFARAGIUS, vol. i. p. 60.

BAR-LE-DUC, or BAR-SUR-ORNAIN, the chief town of the department of Meuse in France. It occupies the declivity and base of a hill, in lat. 48° 46′ 8″ N., long. 5° 9′ 47″ E., on the River Ornain, a tributary of the Marne, 125 miles E. of Paris, and consists of an upper and lower town, the latter being the more modern and respectable of the two. It is a railway station on the Paris-and-Strasburg line, and the Marne and-Rhine canal passes in the immediate vicinity. A college, a normal school, a society of agriculture and arts, and a public library, are among its educational institutions. The only building of mark is the church of St Pierre, which contains a curious figure of a half-decayed body in white marble, originally forming part of the mausoleum of René of Châlons, Prince of Orange. The castle, which formed the nucleus of the upper town, was built by Frederick I., duke of Lorraine, in the 10th century. Louis XI. got possession of the place and caused it to be fortified in 1474. It was dismantled under Louis XIV. in 1670, but retains a few relics of the ancient works. An extensive traffic is maintained in wood, wine, and wool; and the manufactures of cotton stuffs, hats, hosiery, leather, and confections, are considerable, the last-mentioned article being especially celebrated. Population in 1872, 15,175. The district of Bar was governed by a series of counts from 959 to 1354, when it was raised to a duchy, which in 1419 was ceded to René of Anjou, and henceforward followed the fortunes of Lorraine. The motto of the dukes, which has been adopted by the town, was *Plus penser que dire*. Their coins were usually distinguished by *two barbels*.

BAR-SUR-AUBE, the chief town of an arrondissement in the department of Aube, in France. It is a station on the Paris-and-Mulhouse line, and is situated on the right bank of the River Aube, at the foot of Sainte-Germaine, in a picturesque district, the wine of which is much esteemed. It is a pretty little town, with a few remains of its ancient

fortifications. There are several churches of considerable antiquity—the most remarkable being Saint Maclou. In 1814 Bar-sur-Aube was the scene of several conflicts between Oudinot and the Allied Army, in which the latter ultimately gained the victory. Population in 1872, 4453. Long. 4° 44′ E., lat. 48° 13′ N.

BAR-SUR-SEINE, the chief town of an arrondissement in the department of the Aube, in France. In the Middle Ages Bar-sur-Seine was a place of considerable importance, and, according to Froissart, contained no fewer than 900 "hôtels" or mansions. It was devastated in 1359 by marauders from Lorraine, and suffered greatly in the religious wars of the 16th and 17th centuries. A battle was fought here in 1814 between the French and the Allies. Long. 4° 24′ E., lat. 48° 5′ N. Population in 1872, 2798.

BÁRA BÁNKÍ, a district of British India under the jurisdiction of the Chief Commissioner of Oudh, lies between 26° and 28° of N. lat. and 81° and 82° of E. long. It is bounded on the N.W. by the district of Sítápur; on the N. by Bharáich; on the N.E. by Gondá; on the E. by Faizábád; on the S. by Sultánpur and Rai Barelí; and on the W. by Lucknow. The district stretches out in a level plain interspersed with numerous *jhils* or marshes. In the upper part of the district the soil is sandy, while in the lower part it is clayey, and produces finer crops. The principal rivers are the Ghagrá (*Gogra*), forming the northern boundary, and the Gúmtí, flowing through the middle of the district. Both are navigable by country cargo boats. Area, 1735 square miles, of which 1244 are classified as follows:—821 cultivated, 172 culturable but not cultivated, and 251 unculturable waste. Estimated population in 1869, 875,587, or 650 to the square mile, living in 148,166 houses and 2065 villages; Hindus, 748,061; Mahometans, 127,315; Christians, 76. Population in 1872, 1,101,954 souls. Five towns in the district contain over 5000 inhabitants—Nawábganj, 10,496; Rudaulí, 12,517; Fathipur, 7494; Daríábád, 5999; and Rámnagar, 5714. Principal crops, and their acreage:—Rice, 132,459 acres; wheat, 224,583; pulses and other food grains, 304,636; oil-seeds, 23,000; sugar-cane, 29,586; cotton, 509; opium, 3423; indigo, 4875; fibres, 675; tobacco, 6051; and vegetables, 6351 acres. The agricultural stock and beasts of burden in the district consisted in 1871–72 of 83,232 cows and bullocks, 1000 horses, 2590 ponies, 2840 donkeys, 75,928 sheep and goats, 51,060 pigs, 1181 carts, 26,121 ploughs, and 1533 boats. Of the population returned in 1869, 741,989 were agriculturists, and 133,598 non-agriculturists. The means of communication within the district consist of 337 miles of well-made roads, and 78 miles of railway were under construction in 1872. Total revenue in 1871–72, £165,662, of which £157,505, or 95 per cent., was derived from the land. The police consist of (1), a regular constabulary force, 490 strong, maintained at a cost of £6812 per annum; and (2), the village watch, numbering 9558 men; total, 10,048, or about 1 to each 100 of the population, according to the estimate of 1872.

BARAHAT, a town of northern Hindustán, situated in the Himálayas, and within the native state of Garhwál, in 30° 43′ N. lat. and 78° 29′ E. long. The town was almost destroyed in 1803 by an earthquake—a calamity greatly aggravated by the houses having been built of large stones, with slated roofs. From its central position, it maintains a free communication with all parts of the hills, and those who make the pilgrimage to Gangotrí generally halt here and lay in a stock of provisions for the journey. In the neighbourhood stands a curious trident in honour of Siva. The pedestal is of copper, the shaft of brass about 12 feet, and the forks about 6 feet in length. There is no tradition to show the origin of this curious relic; and although it bears a legible inscription, no one has as yet deciphered it. The temple in which it was formerly enclosed was destroyed by the earthquake of 1803.

BARANTE, Amable Guillaume Prosper, Baron de Brugière, an eminent French statesman, and the learned historian of the dukes of Burgundy, was the son of an advocate, and was born at Riom, June 10, 1782. At the age of sixteen he entered the Ecole Polytechnique at Paris, and at twenty obtained his first appointment in the civil service. His abilities secured him rapid promotion, and in 1806 the post of auditor to the council of state was given to him. After being employed in several political missions in Germany, Poland, and Spain, during the next two years, he became prefect of Vienne. At the time of the return of Napoleon I. he held the prefecture of Nantes, and this post he immediately resigned. About this period he married. On the second restoration of the Bourbons he was named councillor of state and Secretary-general of the Ministry of the Interior. About the same time he was elected to the Chamber of Deputies for the two departments of Puy-de-Dôme and Loire Inférieure; but in the following year, in consequence of being under the legal age of a deputy, as required by a new law, he lost his seat. After filling for several years the post of Director-general of Indirect Taxes, he was created, in 1819, a peer of France, and took an active and prominent part as a member of the opposition in the debates of the Upper Chamber. During the same period the leisure hours which he could spare from his political engagements were devoted to literary studies. After the revolution of July 1830, M. de Barante was appointed ambassador to Turin; whence, five years later, he was transferred in the same capacity to St Petersburg. Throughout the reign of Louis Philippe he remained a supporter of the Government; and after the fall of the monarchy in February 1848, he withdrew from political affairs and retired to his country seat in Auvergne. Shortly before his retirement he had been made Grand Cross of the Legion of Honour. As a scholar his *opus magnum* is the *Histoire des Ducs de Bourgogne de la Maison de Valois*, which appeared in a series of volumes between 1824 and 1828. It procured him immediate admission among the Forty of the French Academy; and its great qualities of scholarship, impartiality, accuracy, and purity of style, have given him a place among the greatest French historians. Amongst the other literary works of M. de Barante are a *Tableau de la Littérature Française au dixhuitième Siècle*, of which several editions were published; *Des Communes et de l'Aristocratie* (1821); a French translation of the dramatic works of Schiller; *Questions Constitutionelles* (1850); *Histoire de la Convention Nationale*, which appeared in six volumes between 1851 and 1853; *Histoire du Directoire de la République Française* (1855); *Études Historiques et Biographiques* (1857); *La Vie Politique de M. Royer-Collard* (1861). The version of *Hamlet* for M. Guizot's *Shakespeare* was the work of M. de Barante. He spent the last eighteen years of his life in retirement in Auvergne, and died there on November 22, 1866.

BARANYA, a province in the kingdom of Hungary, extending over 1960 square miles. It lies in the angle formed at the junction of the Danube and the Drave, is traversed by offshoots of the Styrian Alps, and contains one city, 13 market-towns, and 341 villages. The inhabitants number about 283,500, and consist of Magyars, Germans, Croatians, and Servians, a large proportion being Roman Catholics. The greater part of the land is fertile, but a portion of it is marshy and unhealthy. The chief products are corn, wine, flax, tobacco, asparagus, and potash. Warm springs are found at Tapolcza, Siklós, and Harkany. There are some valuable quarries of marble and millstones, and numerous coal-mines. The rearing of sheep

and swine is largely engaged in. The province is subdivided into six circles. The capital is Funfkirchen, with a population of 23,863.

BARANZANO, JEAN ANTOINE, surnamed *Redemptus*, an eminent natural philosopher and mathematician, was born in Piedmont in 1590, and died at Montargis in 1622. He was a Barnabite monk, and was for a time professor of philosophy and mathematics at Annecy. His principal works are *Uranoscopia* (1617), *De Novis Opinionibus Physicis* (1619), *Campus Philosophicus* (1620). He was greatly esteemed by Lord Bacon, with whom he corresponded. Bacon's letter to him (Spedding, *Letters and Life of Bacon*, vii. 374–6) shows that he thoroughly appreciated the new philosophy, and could see its weak as well as its strong points.

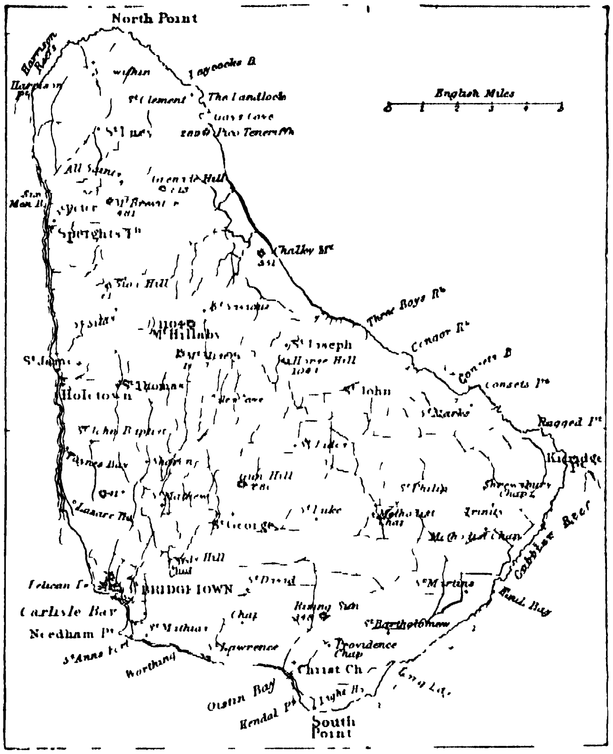
BÁRASAT, a subdivisional town in the district of the 24 Parganás, under the jurisdiction of the Lieutenant-Governor of Bengal, situated in 22° 43′ 24″ N. lat. and 88° 31′ 45″ E. long. For a considerable time Bárásat town was the headquarters of a joint magistracy, known as the "Bárásat District," but in 1861, on a re-adjustment of boundaries, Barasat district was abolished by order of Government, and was converted into a subdivision of the 24 Parganás. Population in 1872—Hindus, 6649; Mahometans, 5133; Christians, 30; and others, 10; total, 11,822. Municipal income, £363; expenditure, £289, 4s.; rate of municipal taxation, 7¼d. per head. It forms a striking illustration of the rural character of the so called "towns" in Bengal, and is merely an agglomeration of 11 separate villages, in which all the operations of husbandry go on precisely as in the adjacent hamlets.

BARATIÈRE, or BARETTIER, JOHN PHILIP, a very remarkable instance of precocious genius, was born at Schwabach near Nuremberg on the 10th January 1721. His early education was most carefully conducted by his father, Francis Baratière, pastor of the French church at Schwabach, and so rapid was his progress that by the time he was five years of age he could speak French, Latin, and Dutch with ease, and read Greek fluently. He then engaged in the study of Hebrew, and in three years was able to translate the Hebrew Bible into Latin or French, or to retranslate these versions into the original Hebrew. From his reading he collected materials for a dictionary of rare and difficult Hebrew words, with critical and philological observations; and when he was about eleven years old translated from the Hebrew Tudela's *Itinerarium*. In his fourteenth year he was admitted Master of Arts at Halle, and received into the Royal Academy at Berlin. The last years of his short life he devoted to the study of history and antiquities, and had collected materials for histories of the Thirty Years' War and of Antitrinitarianism, and for an *Inquiry concerning Egyptian Antiquities*. His health, which had always been weak, gave way completely under these labours, and he died on the 5th October 1740, aged 19 years and 8 months. He had published eleven separate works, and left a great quantity of manuscript materials.

BARATYNSKI, JEWGENIJ ABRAMOVITCH, a distinguished Russian poet, was born in 1792. He was educated at the royal school at St Petersburg, and then entered the army. He served for eight years in Finland, and appears to have got into disgrace on account of some foolish pranks which he had played. During these years he composed his first poem, *Eda*, which bears very manifest traces of his residence in Finland. Through the interest of friends he obtained leave from the Czar to retire from the army, and settled near Moscow. There, so far as his broken health would allow him, he devoted his time to poetry, and completed his chief work *The Gipsy*, which has been spoken of by critics as the best poem of its kind in the Russian language, and as fully equal, if not superior, to the finest productions of Pouschkin. This was his only work of any extent; his health gave way completely, and he died in 1844 at Naples, whither he had gone for the sake of the milder climate. A collected edition of his poems appeared at St Petersburg, in 2 vols., in 1835.

BARBACENA, a town of Brazil, in the province of Minas-Geraes, situated, at the height of about 3500 feet above the sea, in the Sierra Mantiqueira, 150 miles N.W. of Rio de Janeiro. It has low houses and broad streets, and contains a town-hall, a prison, a hospital, founded in 1852 by Antonio Ferreira Armond, and a "school of intermediate instruction," in which French history and geometry are taught. The trade is principally in gold-dust, cotton, and coffee. Population of town and district, 14,000.

BARBADOS, or BARBADOES, the most windward of the Caribbean Islands, is situated in lat. 13° 4′ N. and long. 59° 37′ W., 78 miles E. of St Vincent, the island nearest to it in the Caribbean chain. It lies in the track of vessels, and



Sketch Map of Barbados.

is well adapted to be an *entrepôt* of commerce. It has nearly the size and proportions of the Isle of Wight, being 21 miles in length, and about 14½ miles in its broadest part. It has a superficial area of 106,470 acres, or about 166 square miles,—70,000 acres (besides grass land) are under cultivation, and nearly 30,000 acres of sugar-cane are annually cut. The island is almost encircled by coral reefs, which in some parts extend seaward nearly three miles. There are two lighthouses, one on the south point and another on the south-east coast. A harbour light has also been placed on Needham's Point. The harbour, Carlisle Bay, is a large open roadstead. The inner harbour, or careenage, for small vessels, is protected by a breakwater called the Molehead. Barbados presents every variety of scenery,—hill and valley, smooth table-land and rugged rocks. From one point of view the land rises in a succession of limestone and coral terraces, which indicate different periods of upheaval from the sea. From another there is nothing to be seen but a mass of abruptly-rising rocks. The highest elevation, Mount Hillaby, is 1104 feet above the level of the sea. The island contains but few

streams or streamlets. The gullies or ravines, the result, no doubt, of volcanic agency, are, however, very numerous, radiating from the high semicircular ridge of the coralline formation in a very regular manner to the west, north, and south, but not to the east, where the coral rocks end abruptly. The chalky soil of the district called Scotland (from its assumed resemblance to the scenery of the Highlands) contains *infusoria*, and is altogether different from the deposits of the coral animals which form the superficial area of six-sevenths of the island (91,000 acres). Besides the chalk or marl, sandstone is found in this district. The climate of Barbados is healthy; the temperature equable. For eight months in the year the sea breezes keep it delightfully cool for a tropical country. The extent of cultivation, the absence of swamps (the porous character of the rock immediately underlying the soil preventing accumulations of stagnant water) account for the freedom from miasma. The destruction of the forests may have made the rainfall—upon which successful cultivation depends—somewhat uncertain, but does not seem to have affected it to such an extent as might have been anticipated. The rainfall is caused, apart from elevation, by the exposure of the land to those winds laden with moisture which strike the island at different periods of the year. The average rainfall of the four years 1753-6 was 55·89 inches; of the twenty-five years 1847–71, 57·74 inches; of the single year 1873, 51·26 inches. The sugar production of the island is calculated at 800 hogsheads of 16 cwt. each for every inch of rain.

The N.E. trade-wind blows for three-fourths of the year, and most of the rain comes from the same quarter. March is the driest of the months, and October the wettest; the average rainfall for the former being 1½ inch, and for the latter 9 inches. Leprosy is not uncommon among the negroes, and elephantiasis is so frequent as to be known by the name of "Barbados leg."

Bridgetown. Bridgetown is the capital and port of the island, and the centre of business activity. It contains about 23,000 inhabitants. Over the creek which received the waters from the heights around the Indians had built a rude bridge. This was known for a long time after the British settlement as the Indian Bridge, but as the settlement grew, and after the old bridge had been replaced by a more solid structure, the place received the name of Bridgetown. The town was destroyed by fire in 1666, and rebuilt, principally of stone, upon a larger scale. It suffered again from fire in 1766 and 1845. It has a large town-hall. The Government buildings are a handsome pile close to the sea. The town follows the curve of the bay. Behind it the hills begin to rise, forming the first stepping-stone to the higher lands of the interior. At the southern extremity are the extensive buildings for the garrison, Barbados being the headquarters of the troops in the West Indian command.

Opinions differ as to the derivation of the name of the island. It is probably the Spanish word for the hanging branches of a vine which strike root in the earth. In maps of the 16th century the island appears under various names, among which are *St Bernardo*, *Bernardos*, *Barbudoso*, *Baruodos*, and *Baruodo*. The traces of Indians in this island are more numerous than in any other of the

History. Caribbees. The first recorded visit of Englishmen was in the year 1605, when the crew of the "Olive Blossom" landed, and erected a cross as a memorial of the event, cutting at the same time upon the bark of a tree the words "James, king of England and of this island." This party of adventurers did not settle, but from the time of their visit the history of Barbados begins. That history has some special features. It shows the process of peaceful colonization, for the island, acquired without conquest or bloodshedding, has never since been out of the possession of the British. It was the first English colony where the sugar-cane was planted. Its colonists have almost from the beginning enjoyed representative institutions, and the full measure of English freedom. They have always defended their rights with spirit, and shown consistent loyalty to the Crown. The prominence and accessibility of the island have made it important as a military station in the wars with the French and Dutch. And its varying fortunes show the effects of the commercial legislation of England, from the stringent Navigation Laws of Cromwell down to the repeal of the sugar duties in 1874.

The first patent conveying a proprietary interest in Barbados was granted by James I. to Lord Leigh, afterwards earl of Marlborough. In 1624 a ship, belonging to Sir William Courteen, a rich merchant of London, called at Barbados. The country was found to be thickly wooded, and uninhabited, except by a great number of wild hogs. Sir William Courteen, having received a description of the place, sent out two large ships under the authority of Marlborough's patent. One of these, the "John and William," commanded by John Powell, arrived in February 1625, which is therefore the date of the earliest English settlement in the island. The thirty settlers laid the foundation of a town which they called Jamestown, and chose Captain William Deane their governor. But the earl of Carlisle, having obtained from King James in 1624 the warrant for a grant of all the Caribbean Islands, twenty-two in number, agreed, in 1627, to pay the earl of Marlborough £300 a year for his right to Barbados. The patent in favour of Lord Carlisle passed the great seal on 2d July 1627; but during his absence on a diplomatic mission soon after, William, earl of Pembroke, the Lord Chamberlain, obtained in the interest of Sir William Courteen a grant of several islands, including Barbados. Upon Lord Carlisle's return he obtained the revocation of Lord Pembroke's grant, and the full confirmation of his own rights, upon which he acted in offering to sell parcels of land for an annual payment of 40 lb of cotton. The Society of London Merchants then obtained from Lord Carlisle a grant of 10,000 acres, and they appointed Charles Wolferstone, a native of Bermuda, to proceed with sixty-four persons, and to govern the settlement under a commission from the earl. Wolferstone and his party arrived in July 1628 in the bay, known thenceforth as Carlisle Bay. The antagonism between the earlier settlers under Courteen's auspices and Wolferstone's party broke out into actual fighting. Finding that the validity of his patent was still being disputed, Lord Carlisle obtained a further confirmation of it by the king in April 1629, and at once despatched Sir William Tufton as commander-in-chief with a sufficient force to subdue the rival settlers. In 1645 Philip Bell became governor, and the real progress of the colony began. Good laws were passed, a judicial system was elaborated; the island was divided into eleven parishes, and a general assembly formed by two representatives of each parish, elected by a majority of freeholders. A council had been in existence since the time of Wolferstone.

The first settlers cultivated maize, sweet potatoes, plantains, and yams for their own consumption, and indigo, cotton wool, tobacco, ginger, and aloes for export. Quantities of logwood, fustic, and lignum vitæ were also shipped. But the adaptability of the soil for cane becoming known, and the necessary knowledge for the manufacture of sugar being obtained, this article at once became the great staple of the colony. The value of property very largely increased. The half of an estate of 500 acres, 200 under cane, with buildings and appurtenances, was sold for £7000 about the year 1650, the labourers being slaves from Africa.

It was while the rapid progress of the colony was attracting especial attention, and many persons of family and means, adherents of the royal cause, were finding it a refuge from the troubles at home, that Francis Lord Willoughby of Parham went out as governor, with the consent of King Charles II., who had been proclaimed in Barbados as soon as the news of the execution of Charles I. had arrived. Lord Carlisle had died, and his heir had been entrusted with the duty of paying his debts out of the revenue from the island. Lord Willoughby agreed to take a lease from the new earl of the profits of the colony for twenty-one years, to pay Lord Carlisle one-half, and to accept the governorship, including that of the other islands in the Carlisle grant. Upon his arrival in 1650, notwithstanding the active opposition of a party headed by Colonel Walrond, he procured the passing of an Act acknowledging the king's sovereignty, the proprietary rights of the earl of Carlisle, and his own interest derived from the latter. But the Parliament despatched Sir George Ayscue with a squadron and considerable land forces, to reduce the island to submission to its authority. About the same time the famous Navigation Law was enacted, by which foreign ships were prohibited from trading with British colonies, and imports into England and the dependencies were not allowed in foreign bottoms. This restriction had a great effect upon Barbados, which depended upon foreign importation for a great deal of its provisions. Sir G. Ayscue's expedition appeared off Barbados in October 1651. After one unsuccessful attempt, a landing was effected, and Lord Willoughby's force was routed. The counsels of a moderate party in the island, however, prevailed, and a compromise was effected. A treaty was made declaring the authority of the Parliament, but containing provisions not at all unfavourable to the inhabitants, and reserving even to Lord Willoughby his rights in the island. During the Commonwealth prisoners of war were sometimes sent to Barbados. The expedition of 1655 against St Domingo and Jamaica under Penn and Venables was reinforced by a troop of horse and 3500 volunteers from Barbados. At the Restoration Lord Willoughby went out once more to Barbados and resumed his office. Several of the faithful adherents of the royal cause in the island were made baronets and knights, but the restrictions upon commercial intercourse which had been imposed by the Parliament were made more stringent. Then doubts began to arise in the minds of the planters as to the title by which they held their estates. They had created by their exertions a very valuable property, and the bare possibility of the earl of Carlisle stepping in and dispossessing them caused much discontent. The death of Lord Carlisle brought matters to a crisis. An arrangement was made in 1663 by which the different claimants were satisfied, the proprietary or patent interest was dissolved, and the Crown exercised directly its rights, and undertook the government, although it was not till 1672 that the nomination of the council was taken into the hands of the king. A duty of 4½ per cent. upon the produce of the island was levied in 1663 to satisfy the claims and defray the government expenses. Lord Willoughby received a new commission, and the only practical change effected in the constitution was that all laws were thenceforward made subject to confirmation by the king. In 1665 the colony successfully resisted an attack by the Dutch; but in conducting an expedition against the French in Guadaloupe in 1666, Lord Willoughby was lost in a hurricane, and an eventful and occasionally brilliant career was thus prematurely ended. He was succeeded in the government by his brother, Lord William Willoughby, during whose governorship the division of the Carribean Islands into Windward and Leeward was made. The hurricane of 1675 gave a serious check to the prosperity of the colony. An unsuccessful application was made to the home Government, to remit, on account of the distress that prevailed, the 4½ per cent. duty, which pressed very heavily upon the planters. The island had scarcely recovered from the effects of the hurricane when the supply of labour was restricted and its expense increased by the Royal African Company, at the head of which was the duke of York, receiving a charter for the exclusive supply of slaves to the West India Islands. This company had great influence in the appointment of governors; and in consequence of oppressive proceedings and depreciation of the value of property, many families left the island. A number of persons implicated in the duke of Monmouth's rebellion were sent to Barbados and treated harshly. Duties upon sugar were imposed by the mother country, which were increased at the accession of James II., to 2s. 4d. per cwt. on Muscovado, and to 7s. upon all sugars for common use. From the survey made by governor Sir Richard Dutton in 1683–4, it appears that the population consisted of 17,187 free, 2381 unfree and servants (prisoners of war and persons brought from England under engagements for terms of years), and 46,602 slaves. The number of acres in useful possession was 90,517, and of sugar-works 358. These figures show how rapidly, in spite of all difficulties, the colony had grown in sixty years.

The wars in Europe were reproduced upon a smaller scale, though with equal if not greater intensity, among the different nationalities in the West Indies. In such times the seas swarmed with privateers; and freights were so high as to induce the island Legislature to make a vain attempt to regulate them by law. The news of the peace of Ryswick was received with great joy, and matters remained quiet until the declaration of war against France and Spain in 1702 revived privateering in West Indian waters. Events in the first half of the 18th century do not call for detailed description. It was the custom of the assembly to supplement the salary of the governor (which was paid by the Crown out of the 4½ per cent. duty) by special grants, sometimes of large amount. But this did not prevent many constitutional conflicts between the assembly and the executive. During the war which commenced between England and France in 1756, the West Indies witnessed much fighting, with its attendant suffering. In 1761 a determined attempt was made to break the power of France in the archipelago. Barbados entered with enthusiasm into the project. Guadaloupe had been taken in 1759, and the principal effort now, under Admiral Rodney and General Monckton, was directed against Martinique. In 1762 that island surrendered. Barbados spent £24,000 in raising and equipping her proportion of men in the attacking forces; and in 1765 the House of Commons voted £10,000 as compensation for the expense incurred. By the Treaty of 1763, however, both these islands were restored to France. The constant wars had naturally an injurious effect upon Barbados. During the governorship of the Hon. Edward Hay, who was appointed in 1773, differences of opinion arose as to the state of the island. When the war between England and the American colonies began, the supply of provisions, upon which Barbados depended, necessarily stopped. The assembly addressed a petition to the king, praying for relief; through the interposition of the governor the relief was not immediately granted, but in 1778, when the island was in a very depressed state, the British ministry sent a quantity of provisions for sale at prime cost. With the advent of General Cunninghame as governor another series of contentious years began. In the midst of disputes as to the right of the governor to exact certain fees without the consent of the assembly, a hurricane visited the island and

caused much destruction of property. Parliament in 1782 granted £80,000 for relief, but an attempt to obtain the repeal of the 4½ per cent. duty was again unsuccessful. The French were regaining their ascendency in the archipelago, and had it not been for the great naval victory won by Sir George Rodney, Barbados and the remaining British colonies might have fallen to the enemy. As the 18th century closed, the prospect of the great final struggle with France overshadowed the colonies. The Barbadians energetically put themselves in a state of defence, and at the same time voted and privately subscribed money to assist his Majesty to carry on the war. The peace of Amiens, in 1802, relieved anxiety for a brief interval, but hostilities were soon renewed. When in 1805 Napoleon sent a squadron to the archipelago, with 4000 soldiers, the crisis put Barbados on her mettle. The French fleet was successful in exacting large sums of money from adjacent colonies. Admiral Villeneuve, too, was on his way with a still larger fleet and stronger force. But when Admiral Cochrane arrived off Barbados the safety of the island was secured. Even amid the intense excitement of these events constitutional questions were not forgotten. The governor could only establish martial law when the enemy's fleet was in sight. A premature declaration drew forth a protest from the assembly, and the controversy was only ended when the Home Government asserted the full prerogative of the Crown to impose martial law when necessary for the safety of the island. The most memorable event in 1805 was a flying visit from Lord Nelson in search of a French fleet. In October of the same year the battle of Trafalgar was won, and Bridgetown soon after had its Trafalgar Square and its Nelson statue. In 1809 an expedition sailed from Barbados, under Governor Beckwith, against the French in Martinique. After a bombardment of five days that place was taken. Twelve months later Beckwith similarly attacked Guadaloupe; and when that island was conquered, after some hard fighting, the power of the French in the archipelago was again reduced to its lowest ebb. When the war ended in 1810 in the West Indies, the British were supreme in that region. But danger was threatened from another source. The rupture between Great Britain and the United States in 1812 caused privateering to be resumed to an extent that almost destroyed the commerce of the island, until the abdication of Napoleon and the peace with America in 1814 again brought relief to the colonies. The military history of Barbados ceased at the close of the Peninsular War.

In the meantime Barbadian affairs had attracted notice in Parliament. In 1812 a motion was made in the House of Commons that the 4½ per cent. duty should be applied exclusively to local purposes. A considerable amount of this revenue had been devoted to pensions to persons entirely unconnected with the colony, and it was stated in the House of Commons that part of the money had been appropriated to the king's household in the reign of William III. Nor were the Barbadians themselves backward in stating their grievances. In 1813 they protested against the importation of East Indian sugars into Great Britain, and also against the system of patent offices, by which non-resident officials were able to draw large sums from the island for services which they never performed. By Act of the Parliament 6 Geo. IV. c. 114, 1825, foreign commodities were admitted into the British possessions at moderate rates of duty if the countries sending those articles would give similar privileges to British ships. As the United States refused reciprocity, the West Indian ports were closed against their vessels, and the United States retaliated by prohibiting all intercourse with British colonies. From the operation of the above-mentioned Act an important constitutional question arose. These duties, levied in the name of the king, were to be paid into the local treasury for the uses of the colony, but the customs officers, of course appointed from home, received instructions to retain their own salaries from the revenue. This was denounced by the assembly as illegal, and after a long controversy it was agreed, in 1832, that 10 per cent. should be deducted to defray the expense of collecting the tax. Another question arose which illustrates the relations between England and the colony. By an island Act of 1773, a 2s. 6d. tonnage duty was imposed, but small vessels belonging to residents were only to pay on three voyages a year. By an Act of Parliament in 1832 this exemption was abolished. The assembly protested and denied the right of Parliament to tax colonies which had representative institutions; but Lord Stanley, in 1833, declared that this right existed, although its exercise was a matter of expediency. After the hurricane of 1831, which was perhaps the severest the island had ever experienced, causing 1591 deaths and a destruction of property estimated at more than a million and a half sterling, another urgent appeal was made for the remission of the 4½ per cent. duty, but without effect, although £100,000 was granted by Parliament in 1832 for the relief of the islands which had suffered from the visitation; of this sum Barbados took half. By an Act of Parliament passed in 1838, the 4½ per cent. duty was at length removed, after having been in existence for 175 years.

Slave labour. But a social revolution had begun which was destined to change not so much the prosperity of the colony, as the conditions under which that prosperity arose. From the first settlement, of course, the one great want was labour. As the labour supply increased and became more certain the cultivation expanded, wealth was created, and the importance of the colony grew. In the early days white labour was employed, assisted by Indians obtained from other islands and the mainland of South America, but when the sugar-cane began to be cultivated, negro slaves were imported from Africa. This slave trade, mostly conducted by companies or persons in England, continued until the year 1806, when it was stopped by Act of Parliament. In that year there were 60,000 negroes in the island. This measure was, of course, the first step to the abolition of slavery itself. On the 1st August 1834, the great Act of Emancipation came into force, and four years of apprenticeship began. Out of the 20 millions granted for compensation, Barbados received £1,720,345, being an average payment of £20, 14s. on 83,176 slaves. In consequence of the large population and small extent of uncultivated land, emancipation had not in Barbados such a relaxing effect upon the industry of the negroes as it had in the more thinly-populated colonies. An efficient system of town and rural police was, however, essential. From the time of emancipation the negroes multiplied rapidly. In 1844, out of a total population of 122,198, at least 90,000 were negroes, among whom females were largely in excess. The population, notwithstanding an occasional epidemic and almost continuous emigration, has continued to increase, as the following census returns will show:—

Year.	White.	Coloured.	Black.
1851	15,824	30,059	90,056
1861	16,594	36,128	100,005
1871	16,560	39,578	105,904

The density of the population in 1871 was therefore 966 to the square mile. The gross population at the end of 1873 was estimated at 170,000.

Trade. Production and commerce have undergone great fluctuations. Before the navigation laws the Dutch were good customers, but subsequently the greater part of the produce has been exported to England. In 1767 the total exports of sugar were 24,000 hhds.; in 1805 they were 19,805 hhds. In 1808, probably in consequence of the stoppage of the slave trade, the exports fell to 13,926 hhds. In 1834 they were 28,341 hhds., and in 1846, with the prospect of

the equalization of the English sugar duties upon slave and free grown sugar, they fell to 21,996 hhds. From 1850 to 1872, the average quantity exported annually was 44,000 hhds. The crop of 1873 yielded only 37,337 hhds. The total values of imports and exports in 1850, 1860, and 1873 were as follows:—

	Imports.	Exports.
1850...........	£731,358	£831,534
1860...........	941,761	981,294
1873...........	1,193,814	1,024,083

Of the imports £365,189 were from the United Kingdom, £171,592 from British Colonies, £485,275 from the United States, and the remainder from other foreign countries. The exports were thus distributed:—£471,175 to the United Kingdom, £388,791 to British Colonies, and £164,166 to foreign countries, including £125,640 to United States. Of the total exports 65 per cent. consisted of native productions, sugar, molasses, and rum. The balance consists of the transit trade, which contributes largely and increasingly to the commercial business of the island. The number of ships entered from the United Kingdom in 1873 was 74, tonnage, 22,590; from United States, 181, tonnage, 40,725; from British North American Colonies, 125, tonnage, 19,283; from West Indies and Guiana, 851, tonnage, 41,323. The total number of ships entered was 1406, with a tonnage of 153,400 tons. But in 1873 the crop was deficient. The figures for 1875 will show the employment of a much larger quantity of shipping.

Barbados is gradually becoming the central mart for all the Windward Islands, even Trinidad finding it more advantageous to derive her breadstuffs, &c., from this quarter, than to import them direct from the continent. There was formerly an extensive whale-fishery round the island, and recently attempts have been made to revive its importance. Many other fishes would afford an excellent return, but this source of wealth is in great measure neglected. The anchovy is frequently driven up in shoals on the coast. The flying-fish is one of the principal articles in the Bridgetown market; barracoudas, sharks, and conger-eels are also exposed.

Government. The local government consists of a governor (who is also governor-in-chief of St Vincent, Grenada, Tobago, and St Lucia); a legislative council (the members of which form as well an executive council), appointed by the sovereign, and holding office during pleasure, and the house of assembly. In former times the council exercised judicial functions, but in 1841 a chief-justice was appointed, and recent improvements have relieved the council of their equity and nearly all their appellate jurisdiction. The island is still divided into 11 parishes, each of which sends two representatives to the assembly. In addition to the parishes, Bridgetown sends two members. The number of voters, with the necessary property qualification, is about 1350. The business of the legislature is conducted according to the forms of the English Parliament, even to the election of a speaker to preside over the assembly, the initiation of money bills in that house, and the assertion of the right to exclude strangers. The assembly is elected annually.

Revenue. The revenue of the island in 1873 was £123,676, derived mainly from import duties, tonnage and port-dues, licences, and rum duty. The expenditure was £121,796. The total parochial taxation in 1873 was £31,569, which brings the gross amount of general taxation to £155,245, being at the rate of £1, 9s. 1d. per acre, or 17s. 6d. per head of population. The island is free from debt. The judicial establishment includes a court of chancery, which is conducted according to the rules, and follows the decisions, of the English court; a court of common pleas, criminal sessions, &c. The common law of England, modified by local enactments, is in force in Barbados.

Religion. The Church of England is the prevailing form of religion in the island. In 1871 the population was thus classified:—Church of England, 144,080; Wesleyans, 12,267; Moravians, 4733; and Roman Catholics, 513. Each parish has a rector, and there are twenty-eight curates in the island, all paid by the colonial revenue. The other denominations are also now entitled to grants. In the early days of the plantation, the clergy were paid by one pound of sugar for every acre of land in their parish. The first bishop of Barbados (the diocese including other colonies) was the Right Rev. W. Hart Coleridge, who arrived in 1825, and remained till 1842, when the diocese was divided, and the bishopric of Antigua founded. Trinidad has recently withdrawn from the diocese of Barbados and the Windward Islands, and founded a separate bishopric.

Education. Education is extending in Barbados. There were in 1873, 79 primary schools with 8000 scholars on the register, and 67 infant schools, with 5500 scholars, but the average attendance is much smaller. The Government expenditure on these schools for the year was £4000. The principal educational establishment is Codrington College, founded by Colonel Christopher Codrington. He bequeathed two estates, known as Consett's and Codrington's, to the Society for the Propagation of the Gospel. They consisted of 763 acres, 3 windmills, sugar buildings, 315 negroes, and 100 head of cattle. The society came into possession in 1712. The will declared that the plantations were to be continued, and 300 negroes always kept upon them; that professors and scholars were to be maintained; and physic, chirurgery, and divinity were to be studied and practised. The college was commenced in 1716, and has seen many vicissitudes. One of its principal objects has been the preparation of candidates for holy orders. There are several theological scholarships of the value of £30 per annum from the college funds, and three of similar value paid by the Colonial treasury. There is a school, recently assisted by the public funds, called the Codrington Collegiate Grammar School, in close connection with the college. Harrison's College, in Bridgetown, established on an old foundation, has been liberally supported by the Legislature, and promises useful results.

(J. L. O.)

BARBAROSSA, meaning *red-beard*, the name of two celebrated Turkish corsairs of the 16th century. They were the sons of a Roumelian sipahi who had settled in Mitylene after the capture of that island by Mahomet II., and who appears to have embraced Islamism. The elder of the two is generally called Aruch, Horuk, or Ouradjh; the name of the younger was Khizr, but he was afterwards called by the sultan *Khair-ed-deen*, meaning "one good in the faith," which was corrupted by the Christians into Hayraddin. The brothers early betook themselves to piracy; and after various successes and reverses, they acquired sufficient wealth and renown to enable them to fit out a small fleet with which they ravaged the shores of the Mediterranean, and became the pests of that sea. A richly laden vessel which they presented to the Sultan at Constantinople procured for them honorary caftans and recognition of their services. About the year 1516, after having been for some time in the service of the bey of Tunis, they began to acquire considerable possessions on the coast of Africa. Hayraddin seized the island of Shershel, and Aruch gained a footing in Algiers. The latter began to extend his conquests into the district of Telmessan or Tlemcen, and was resisted by the Arabs, who summoned the Spaniards of Oran to their assistance. Aruch fell in battle in 1518, and was succeeded at Algiers by Hayraddin, who, after the reigning prince, Selim, was removed (in what way is somewhat doubtful), consolidated his power by placing himself under the Sublime Porte. Solyman, who was delighted at obtaining so much territory at such a small cost, conferred upon Hayraddin the title of *Begler-beg* of Algiers. The power of the pirates rapidly increased; Algeciras, a small island opposite Algiers, was taken from the Spaniards after an obstinate resistance, and was united with the mainland by a mole. The coasts of the Mediterranean were completely at the mercy of Barbarossa, who carried off immense numbers of slaves. In 1533, when Solyman was about to make war upon his great rival, Charles V., Hayraddin joined him with a number of ships. He was received with great honour, and made admiral (*capitan-pasha*) of the fleet. His greatest exploit was the capture of Tunis, in which he obtained a footing by adopting the cause of a rival prince. As soon as he had deposed Muley Hassan, the reigning sovereign, he seized the town for himself and held it despite the resistance of the people. Charles V., however, sent out a great fleet, under Andrea Doria, who retook the town after a protracted siege. Barbarossa escaped to Algiers, collected his fleet, and again swept the seas. He plundered the coasts of Italy, captured Castelnuova, and inflicted a severe defeat on Doria. He died at Constantinople 4th July 1546. (See Von Hammer, *Geschichte des Osmanischen Reiches*, iii. 164, *seq.*; also *Blackwood's Magazine*, vol. lii.) The Emperor Frederick I. is very frequently designated by the surname Barbarossa.

BARBARY, the general designation of that part of Northern Africa which is bounded on the E. by Egypt, W. by the Atlantic, S. by the Sahara, and N. by the Mediterranean, and comprises the states of Marocco, Algeria, Tunis, and Tripoli. The name is derived from the *Berbers*, one of the most remarkable races in the region. (See AFRICA, vol. i. p. 251, ALGERIA, MAROCCO, TRIPOLI, TUNIS.)

BARBASTRO, a fortified city of Spain, in the province of Huesca, on the River Vero, near its junction with the Cinca. It has an interesting cathedral and seven other churches, with several hospitals. It was recovered from the Moors in 1065. The brothers Argensola were born here. The inhabitants are chiefly employed in tanning and currying leather. Long. 0° 20′ W., lat. 41° 54′ N.

BARBAULD, MRS ANNA LETITIA, was born at Kibworth-Harcourt, in Leicestershire, on the 20th June 1743. Her father, the Rev. John Aikin, was a Presbyterian clergyman, who conducted a private school at that place. He instructed his daughter very carefully, and besides the usual female accomplishments she acquired a good knowledge of Latin and a fair knowledge of Greek. In 1758 Mr Aikin removed his family to Warrington, to act as theological tutor in a dissenting academy there. In 1773 Miss Aikin, at the earnest request of her brother, Dr John Aikin, known as the author of the *Evenings at Home*, consented to publish some of her poems. The volume was very successful, four editions being called for in the course of the year. In 1774 she married the Rev. Rochemont Barbauld, a Presbyterian minister, descended from a French Protestant family who had settled in England. He had been educated in the academy at Warrington, and had recently been appointed to a church at Palgrave, in Suffolk. There he began a private boarding-school, in the work of which he was most ably assisted by Mrs Barbauld, who superintended the younger pupils. Among those who passed through her hands, and who looked back with pleasure to the instruction given by her, were Sir William Gell, Lord Denman, and William Taylor of Norwich. The *Hymns in Prose* and the *Early Lessons* were written by her about this time for the use of her young charges, and proved admirably adapted for the purpose of instructing children. They have been frequently reprinted. In 1785 she left England for the Continent with her husband, whose health had been seriously impaired. On their return after a residence of about two years, Mr Barbauld was appointed to a church at Hampstead, where they resided till 1802. In 1792 Mrs Barbauld assisted her brother Dr Aikin in the composition of the popular series *Evenings at Home*, but, it is said, contributed only a few pieces. In 1795 she published an edition of Akenside's *Pleasures of Imagination*, with a critical essay; and two years later, she edited in a similar manner Collins's *Odes*. In 1804, after their removal to Stoke Newington, she published a selection of papers from the English Essayists, and a selection from Richardson's correspondence, with a biographical notice. The critical remarks prefixed to these publications have been much admired; they are generally judicious, in good taste, and well expressed. In 1810 she published a collection of the *British Novelists*, with biographical and critical notices. In the following year she published her longest poem, entitled *Eighteen Hundred and Eleven*, depicting the political and social events of the time, and giving rather a gloomy view of the existing state and future prospects of Britain. The poem is in many respects scarcely worthy of the author's reputation. Mrs Barbauld died on the 9th March 1825; she had been a widow from 1808. A collected edition of her works, with Memoir, was published by her niece, Miss Lucy Aikin, in 2 vols., 1826. (See A. L. Le Breton, *Memoir of Mrs Barbauld*, 1874; G. A. Ellis, *Memoir of Mrs A. L. Barbauld*, 1874.)

BARBER, one whose occupation it is to shave or trim beards. In former times the barber's craft was dignified with the title of a profession, being conjoined with the art of surgery. In France the barber-surgeons were separated from the perruquiers, and incorporated as a distinct body in the reign of Louis XIV. In England barbers first received incorporation from Edward IV. in 1461. By 32 Henry VIII. c. 42, they were united with the company of surgeons, it being enacted that the barbers should confine themselves to the minor operations of blood-letting and drawing teeth, while the surgeons were prohibited from "barbery or shaving." In 1745 barbers and surgeons were separated into distinct corporations by 18 George II. c. 15. The barber's shop was a favourite resort of idle persons; and in addition to its attraction as a focus of news, a lute, viol, or some such musical instrument, was always kept for the entertainment of waiting customers. The barber's sign consisted of a striped pole, from which was suspended a basin, symbols the use of which is still preserved. The fillet round the pole indicated the ribbon for bandaging the arm in bleeding, and the basin the vessel to receive the blood.

BARBERINI, the title of a powerful family, originally of Tuscan extraction, who settled in Florence during the early part of the 11th century. They acquired great wealth and influence, and in 1623 Maffeo Barberini was raised to the papal throne as Urban VIII. He made his brother, Antonio, and two nephews, cardinals, and gave to a third nephew, Taddeo, the principality of Palestrina. Great jealousy of their increasing power was excited amongst the neighbouring princes, and Odoardo Farnese, duke of Parma, made war upon Taddeo and defeated the papal troops. After the death of Urban in 1644 his successor, Innocent X., showed hostility to the Barberini family. Taddeo fled to Paris, where he died in 1647; but the others after a short period returned to Italy and had their property restored. The principality of Palestrina is still in the hands of the family; and their magnificent palace and library at Rome give evidence of their wealth and magnificence.

BARBEYRAC, JEAN, an able writer on the principles of natural law, was the nephew of Charles Barbeyrac, a distinguished physician of Montpellier, and was born at Beziers in Lower Languedoc, in 1674. He removed, along with his family, into Switzerland after the revocation of the Edict of Nantes, and there studied jurisprudence. After spending some time at Geneva and Frankfort-on-the-Main, he became professor of belles lettres in the French school of Berlin. Thence, in 1711, he was called to the professorship of history and civil law at Lausanne, and finally settled as professor of public law at Groningen. He died in 1744. His first published work of any extent was the curious *Traité du Jeu*, 1709, in which he defends the morality of games of chance. His fame rests chiefly on the preface and notes to his translation of Puffendorf's celebrated treatise *De Jure Naturæ et Gentium*. In fundamental principles he follows almost entirely Locke and Puffendorf; but he works out with great skill the theory of moral obligation, referring it to the command or will of God. He indicates the distinction, developed more fully by Thomasius and Kant, between the legal and the moral qualities of action. The principles of international law he reduces to those of the law of nature, and combats, in so doing, many of the positions taken up by Grotius. He rejects the notion that sovereignty in any way resembles property, and makes even marriage a matter of civil contract. Barbeyrac also translated Grotius's *De Jure Belli et Pacis*, Cumberland's *De Legibus Naturæ*, and Puffendorf's

smaller treatise on obligations. Among his own productions are a treatise, *De la Morale des Pères*, and a history of ancient treaties, contained in the *Supplément au grand corps diplomatique*.

BARBIERI, Giovanni Francesco (otherwise called Guercino, from his squinting), an eminent historical painter, was born at Cento, a village not far from Bologna, in 1590. His artistic powers were developed very rapidly, and at the age of seventeen he was associated with Benedetto Gennari, a well-known painter of the Bolognese school. The fame of the young painter spread beyond his native village, and in 1615 he removed to Bologna, where his paintings were much admired. His first style was formed after that of the Carracci; but the strong colouring and shadows employed by Caravaggio made a deep impression on his mind, and for a considerable period his productions showed evident traces of that painter's influence. Some of his latest pieces approach rather to the manner of his great contemporary Guido, and are painted with more lightness and clearness. Guercino was esteemed very highly in his lifetime, not only by the nobles and princes of Italy, but by his brother artists, who placed him in the first rank of painters. He was remarkable for the extreme rapidity of his execution; he completed no fewer than 106 large altar pieces for churches, and his other paintings amount to about 144. His most famous piece is thought to be the Sta Petronilla, which was painted at Rome for Gregory XV. and is now in the Capitol. Guercino continued to paint and teach up to the time of his death in 1666. He had amassed a handsome fortune by his labours.

BARBIERI, Paolo Antonio, a celebrated painter of still life and animals, the brother of Guercino, was born at Cento in 1596. He chose for his subjects fruits, flowers, insects, and animals, which he painted after nature with a lively tint of colour, great tenderness of pencil, and a strong character of truth and life. He died in 1640.

BARBOUR, John, the author of the great Scottish national poem *The Bruce*, was born, probably in Aberdeenshire, about the beginning of the 14th century. He was a contemporary of Chaucer and Gower; but so little is known of his life, that the very date of his birth can be only approximately given as about 1316. In 1357, as we learn from a safe-conduct permitting him to visit Oxford for the purpose of study,[1] he held the position of archdeacon of Aberdeen. In 1364 he was again permitted to enter England for a similar purpose,[2] and in 1368 he received letters of safe-conduct authorizing him to pass through England on his way to France,[3] whither, it may be conjectured, he was proceeding in order to visit the famous university of Paris. From this date to his death, which took place probably in March 1395, notices of him are slightly more numerous. In 1373 he is described as holding the office of clerk of audit of the king's household.[4] About the same time he must have been busily engaged in the composition of his great work, for, as he himself tells us, his poem was more than half finished in 1375.

> "In the tyme of the compiling
> Off this buk this Robert wes King;
> And off his kynrik passit was
> Fyve yer; and wes the yer off grace
> A thousand, thre hundyr, sevynty
> And fyve, and off his eld sixty."[5]

A sum of ten pounds, which was paid to the poet by the king's orders in 1377,[6] was in all probability a royal gift on the completion of the work. Barbour seems indeed to have been well treated by his sovereign; he received a perpetual annuity of twenty shillings[7] (which he bequeathed to the dean and chapter of Aberdeen as payment of a yearly mass to be said for his soul), tithes of the parish of Rayne in the Garioch, and a crown wardship, always a lucrative office in those times. A further bounty of ten pounds a year during life, granted in 1388, was probably a reward on the completion of the poet's second large work, *The Brute*. The cessation of payment of this annuity enables us to fix with some accuracy the date of Barbour's death.

The Bruce, which is Barbour's principal poem, although it is almost the sole authority for the events of the period, is not to be considered as merely a rhyming chronicle.[8] His theme was freedom and the liberation of his country from the dominion of a foreign people. The age of Bruce was the age of Scottish chivalry, and the king himself presented the most perfect model of a valiant knight. With such a crisis and such a hero, therefore, it is not surprising that Barbour should have achieved a work of lasting fame.

The poem begins with an account of the succession to the Scottish crown after the death of Alexander III. In this part of his poem Barbour has made a slight anachronism. He makes his hero compete with John Baliol for the crown of Scotland, while it was his grandfather, the Lord of Annandale, who unsuccessfully contested the right. Then follows a lamentable account of the desolation of the country and the oppression of the people by the English. Bruce's energetic actions to free his country, and his romantic adventures, which form so interesting an episode in Scottish history, are narrated with great minuteness, down to the battle of Bannockburn, which is described with all its interesting details. At this point the national epic properly ends; but Barbour further relates the expedition of Bruce to Ireland, and the exploits of Douglas and Randolph on the borders, and concludes with an account of the deaths of King Robert and his gallant knights.

The next in order of his writings was that before referred to, called *The Brute*, of which it is believed no MS. exists, unless the supposition of Mr Henry Bradshaw, librarian of the university of Cambridge, be correct, that about 2000 lines of two MS. *Troy-books*, by Lydgate, preserved in the Cambridge and Bodleian Libraries, form part of this poem. It appears to have comprised a genealogical history of the kings of Scotland, deducing their origin from the great mediæval hero, Brutus, son of Ascanius, and grandson of Æneas, supposed to have been the first king of Britain. The existence of such a work is fully established by various passages in Wyntown's *Cronykil*.

> "This Nynus had a sone alsua,
> Sere Dardane lord of Frygia.
> Fra quham Barbere sutely
> Has made a propyr Genealogy,
> Tyl Robert oure secownd kyng,
> That Scotland had in governyng.

> "Of Bruttus lyneage quha wyll her.
> He luk the tretis of Barbere,
> Mad in-tyl a Genealogy
> Rycht wele, and mare perfytly
> Than I can on ony wys
> Wytht all my wyt to yowe dewys."

> "The Stewartis oryginale
> The Archedekyne has tretyt hal
> In metyre fayre."[9]

It is also referred to by Barbour himself in the following passage:—

> "Als Arthur, that throw chevalry
> Maid Bretane maistres and lady

Off twelf kinrykis that he wan;
And alsua, as a noble man,
He wan throw bataill Fraunce all fre,
And Lucius Yber wencusyt he,
That then of Rome was emperour;
Bot yeit, for all his gret valour,
Modreyt his systir son him slew,
And gud men als ma than inew
Throw tresoune and throw wikkitnes;
The Broite beris thairoff wytnes."[1]

The last of the works of Barbour was his *Book of Legends of Saints*, which contained, as the author tells us—

"Storyss of sere haly men
That to pless God vs may kene."

The manuscript of this work (which was brought to light a few years ago by Mr Bradshaw) is preserved in the library of the university of Cambridge. The *Legends* are contained in a tall, narrow volume of paper, closely written in an unmistakably Scottish hand, containing a great many thousand lines in the usual verse of Barbour. This, taken in connection with certain incidental notices which the writer gives of himself, and certain stories which he tells of what happened in his time, leaves little room for doubt as to the author. The following extract from the account of a cure performed by St Ninian upon a native of Elgin may be given as a specimen of these legends:—

"A lytil tale yit herd I tell
That in to my tyme befel
Of a gudman in Murefe borne
In Elgyne and his kine beforne
And callit vas a faithful man
Vithall thame that hyme knew than
And this man trastely I say
For I kend hyme weile mony day
Johne Balormy ves his name
A man of ful gud fame
And in processe of tyme tyd hyme
Til haf the worme in til his lyme
And wrocht sa in his schank and kne
That bath ware thai lyk tynt to be."[2]

The works of Barbour are interesting in a philological point of view. At one time they were regarded as the first written in what was termed the ancient Scottish, a special language, which was supposed to have been derived directly from the Suio-Gothic, or the Mœso-Gothic of Ulphilas. The extraordinary circumstance, however, was that Barbour and other early Scottish poets, such as Wyntown, James I., and Lyndsay, speak of the language as "Inglis." In *The Bruce* the following passage occurs:—

"This wes the spek he maid perfay
As is in *Ynglis* toung to say."[3]

It is now generally admitted that these poets wrote in a language founded on the Anglo-Saxon of the northern type, and nearly identical with that spoken in the northern half of England, which was general from the Trent to the Forth, and northwards on the eastern coast as far as Aberdeen. In this extensive district a Doric dialect of English was general, and in the 14th century there was no greater difference between the written language of York and of Eastern Scotland than there is now between the modern speech of Aberdeen and Edinburgh.[4]

According to Warton,[5] Barbour has adorned the English language by a strain of versification, expression, and poetical imagery, far superior to the age. Dr Nott[6] remarks that he has given his countrymen a fine example of the simple, energetic style, which resembled Chaucer's best manner, and wanted little to make it the genuine language of poetry. Simplicity may be said to be the main feature in the plan and conduct of his poems. His story is throughout his first and chief object, and he shows great anxiety lest in any point of the actual adventures he may mislead his reader. He prays that he may say "nought bot suthfast thing," and he was the first who did so with some of the graces of the fables of romance. He has, however, a heart for every kind of nobleness. His far-famed encomium on political freedom is distinguished by a manly and dignified strain of sentiment:—

"A! fredome is a noble thing!
Fredome mayss man to haiff liking,
Fredome all solace to man giffis:
He levys at ess that frely levys!
A noble hart may haiff nane ess,
Na ellys nocht that may him pless,
Gyff fredome failyhe; for fre liking
Is yharnyt our all othir thing.
Na he that ay hass levyt fre,
May nocht knaw weill the propyrte,
The angyr, na the wrechyt dome
That is cowplyt to foule thyrldome:
Bot gyff he had assayt it,
Than all perquer he suld it wyt,
And suld think fredome mar to pryss
Than all the gold in warld that is."[7]

The following passage cannot be passed without particular notice, the annals of heroes furnish but few instances of so pleasing a nature, whether it be that heroes seldom stoop to actions of mere benevolence, or that their historians do not think it of much importance to transmit such actions to posterity:—

"The king has hard a woman cry;
He askyt quhat that wes in hy.
'It is the layndar, Schyr,' said ane,
'That her child-ill rycht now has tane,
'And mon leve now behind ws her;
'Tharfor scho makys yone ivill cher',
The king said, 'Certis it war pite
'That scho in that poynt left suld be;
'For certis I trow thar is na man
'That he ne will rew a woman than.'
Hiss ost all thar arestyt he,
And gert a tent sone stentit be,
And gert hyr gang in hastily,
And othyr wemen to be hyr by,
Quhill scho wes deliuer, he baid;
And syne furth on his wayis raid:
And how scho furth suld caryit be,
Or euir he furth fur, ordanyt he.
This wes a full gret curtasy,
That swilk a king, and sa mighty,
Gert his men duell on this maner
Bot for a pouir lauender."[8]

It has been stated that Barbour presents us with but few studies of natural scenery. His description of spring is, however, worthy of his muse, and contrasts favourably with any of the poetry of the period:—

"This wes in ver, quhen wynter tyde,
With his blastis hidwyss to byde,
Was our-drywyn, and byrdis smale,
As turturis and the nychtyngale,
Begouth rycht meraly to syng;
And for to mak in thair singyng
Swete notis, and sownys ser,
And melodys plesand to her;
And the treis begouth to ma
Burgeons, and brycht blomys alsua,
To wyn the helyng off thair hewid,
That wykkyt wyntir had thaim rewid."[9]

Of Barbour's *Bruce* neither the original manuscript nor any contemporary copy is known to exist. It is a some-

[9] *Ibid.*, p. 89.

what remarkable circumstance that the earliest specimen of Barbour's language is to be found in extracts inserted by Wyntown in his *Cronykil*, which may be set down as belonging to the year 1440.[1] A valuable manuscript of *The Bruce* is preserved in the Advocates' Library, Edinburgh, which was penned by John Ramsay in 1489. Ramsay is supposed to be the same person that was afterwards prior of the Carthusian monastery at Perth. This transcript is stated to have been executed at the request of Simon Lochmalony, vicar of Moonsie.

Another manuscript exists in the library of St John's College, Cambridge, and is dated 1487. The handwriting is very like that of the Advocates' Library manuscript, and from the initials of the transcriber being J. R., it is supposed that this is another transcript made somewhat earlier by the same scribe. This last manuscript affords perhaps the best readings, but each serves to correct errors and to supply omissions of the other.

The printed editions are almost a century later. The first known edition of *The Bruce* is believed to have been printed at Edinburgh in 1570–71, but of this only one imperfect copy is known to exist. The next known edition is that printed at Edinburgh by Andro Hart in 1616, only one copy of which is extant. Another edition was printed by Hart in 1620. Editions were issued by Andrew Anderson, Edinburgh, 1670, 12mo; Robert Saunders, Glasgow, 1672; Robert Freebairn, Edinburgh, 1715 or 1716 (issued with a false title page in 1758); Carmichael and Miller, Edinburgh, 1737. John Pinkerton issued an edition in 1790, printed at London, in 3 vols. 8vo, which he styles "the first genuine edition." It was taken from the Advocates' Library manuscript, but, as his transcript was executed neither by himself nor under his immediate inspection, many gross inaccuracies were suffered to remain uncorrected. Dr John Jamieson printed an edition at Edinburgh in 1820, in 4to. This was a careful print of the Advocates' Library manuscript. Mr Cosmo Innes printed an edition for the Spalding Club in 1856. It was made from a collation of the Advocates' Library and the Cambridge manuscripts. The Rev. W. W. Skeat is at present (1875) engaged in editing an edition for the Early English Text Society (extra series), 1870–75. This edition is founded on the Cambridge manuscript, carefully collated with the Edinburgh manuscript and with Hart's edition of 1616, and occasionally with Anderson's edition of 1670. (J. SM.)

BARBUDA, one of the lesser Antilles or Caribbean islands, is 10 miles in length by about 8 in breadth, presenting a very flat surface, covered to a great extent with woods, in which deer abound. Many varieties of shell-fish and other fish are found on the coast, which is also frequented by large flocks of water-fowl. The part of the island under cultivation is fertile; corn, cotton, sugar, tobacco, and indigo are grown; and the rearing of cattle is one of the principal occupations. So salubrious is the climate that Barbuda serves as a kind of *sanitarium* for the adjacent islands. The inhabitants, who number less than 2000, are mainly negroes. The island was annexed to Britain in 1628, and was bestowed in 1680 on the Codrington family, in whose possession it still remains. The north point is in lat. 17° 33′ N. and long. 61° 43′ W.

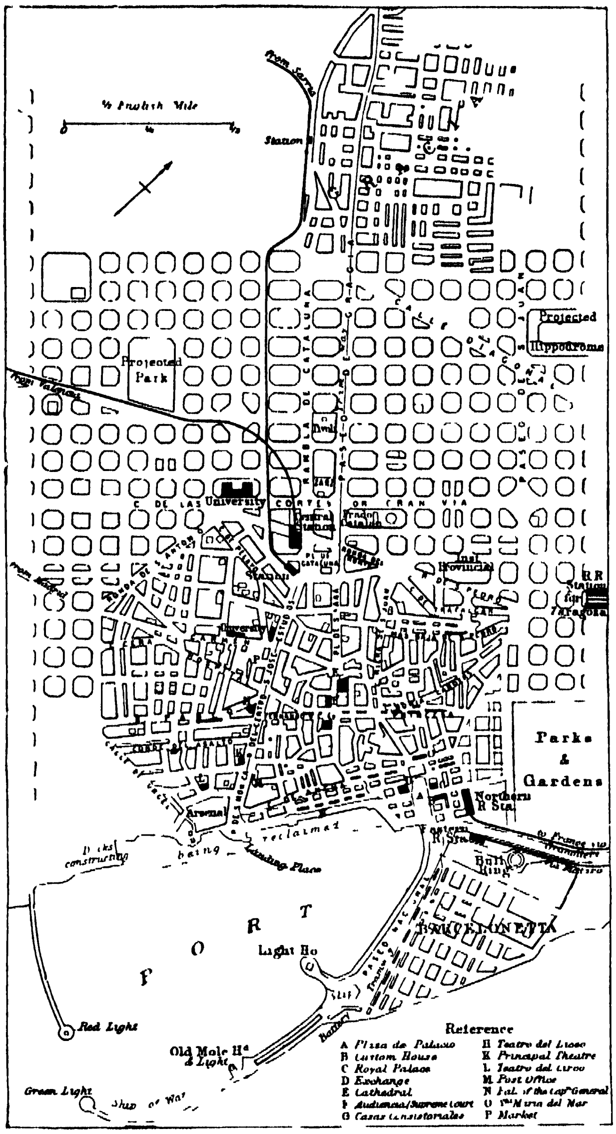
BARCA, a maritime district of Northern Africa, which formerly belonged to Tripoli, but was raised in 1869 to be a separate province immediately dependent on Constantinople. It extends from the Gulf of Sert (the ancient Syrtes) to the Egyptian frontier, between lat. 30° and 33° N. and between long. 20° and 25° E., and has an area of about 60,700 square miles. This territory is traversed from east to west by a mountain chain varying in height from 400 or 500 to upwards of 1800 feet. A great part of Barca, particularly towards the coast, is very fertile, abounding with excellent pasturage, and producing large supplies of corn. The chief town is Bengazi.

BARCA, an ancient city in Cyrenaica, and within the above district, to which it gave name. Its ruins are now known as *El-Medinah*. It was situated between Cyrene (now *Grennah*) and Hesperides (now *Bengazi*), about 11 miles distant from the sea, on the top of the rising ground that overlooks the Syrtes. It was founded about 554 B.C. by a colony from Cyrene, who fled from the ill-treatment of Arcesilaus II., and obtained the co-operation of a number of Libyans. About forty-four years after its foundation it suffered severely from the revenge of Pheretima, the mother of Arcesilaus III., being captured and pillaged by the Persians, to whom she had appealed for assistance, while large numbers of its inhabitants were led captive to Bactria. In the time of the Ptolemies the founding of a new city, Ptolemais, on the sea-coast drew away from the older site a large part of the population; but Barca continued to exist for several centuries after the Christian era, and even seems to have risen again into importance under the Arabs. The ruins are few, and are thought to be those of the Arab city.

BARCELONA, formerly the capital of the kingdom of Catalonia, and now the chief town of the Spanish province to which it gives its name, is a flourishing city and seaport on the shore of the Mediterranean, in lat. 41° 22′ N. and long. 2° 9′ E., between the rivers Bésos (*Bætulo*) on the north and the Llobregat (*Rubricatus*) on the south. It stands on the sloping edge of a small but fertile plain now covered with villas and gardens. Immediately to the south-east rise the Montjuich hills to the height of 650 feet, crowned by an important fortification; while on the west, the north, and the north-east, the view is bounded by the heights of San Pedro Martio, Valcanca, and Moncada. Barcelona was formerly surrounded by a strong line of ramparts, and defended, or, more correctly, overawed by a citadel on the north-east, erected in 1715 by Philip V. on Vauban's principle; but these fortifications being felt as a painful restriction on the natural development of the city, were, in spite of the opposition of the central Government, finally abolished by the local authorities in 1845. The walls of the moat were utilized for the cellars of the houses which soon occupied the site of the ramparts, and the ground, which had been covered by the citadel, was laid out in horticultural gardens. A rapid extension of the city to the north-west took place, and in 1860 an elaborate plan for the laying out of new districts received the royal sanction. Barcelona thus comprises an old and a new town, differing from each other in many important features, the former still consisting for the most part of irregular and narrow streets, while the latter has all the symmetry and precision of a premeditated scheme. The buildings of the old town are chiefly of brick, from four to five stories in height, with flat roofs, and other Eastern peculiarities; while in the new town hewn stone is very largely employed, and the architecture is often of a modern English style. To the south-east, on the tongue of land that helps to form the port, lies the suburb of Barceloneta. It owes its origin to the marquis de la Mina, who, about 1754, did so much for the city, and is regularly laid out, the houses being built of brick after a uniform pattern. The main street or axis of the old town is the *Rambla*, a favourite resort of the higher classes, which has a fine promenade planted with plane-trees running down the middle, and contains the principal hotels and theatres of the city. Among the most important of the squares are the Plaza de Palacio, the Plaza Real, and the Plaza del Teatro. The Paseo de San Juan and the Gardin del

[1] *Cronykil of Scotland*, book viii. c. 2 and 18.

General to the north-east of the town are being removed. The site of the former is to be occupied by a large market, while the latter is to be absorbed into the Park. Barcelona is the see of a bishop, and, like most Spanish towns, has a large number of ecclesiastical buildings, though by no means so many as it once possessed. If Barceloneta on the one hand, and Garcia, a suburban village, on the other, be included, the number of churches amounts to twenty-seven, and eighteen of these are *parroquias;* while no fewer than eighteen convents were still standing in 1873. The cathedral, erected between 1298 and 1448, but not yet finished, is a spacious building in the Pointed style, and contains the tomb of Santa Eulalia, the patron saint of the city. Its stained glass windows are among the finest in Spain, and it possesses archives of great value. Santa Maria del Mar, Santos Justo y Pastor, San Pedro de las Puellas, and San Pablo del Campo, are all churches worthy of mention. San Miguel in Barceloneta, which preserved a curious ancient mosaic and contained the tomb of the marquis de la Mina, has been taken down.



Ground-Plan of Barcelona.

The educational institutions of Barcelona have from an early period been numerous and important. The university (*Universidad Literaria*) was originally founded in 1430 by the magistracy of the city, and received a bull of confirmation from Pope Nicholas V. in 1450, possessing at that time four faculties and thirty-one chairs, all endowed by the corporation (*vide* Capmany's *Memorias*). It was suppressed in 1714, but restored in 1841, and now occupies an extensive building in the new town. There are, besides, an academy of natural sciences, a college of medicine and surgery,—confirmed by a bull of Benedict XIII. in 1400,—an academy of fine arts, a normal school, a theological seminary, an upper industrial school, an institution for the education of deaf-mutes, a school of navigation, and many minor establishments. Gratuitous instruction of a very high order is afforded by the Board of Trade to upwards of two thousand pupils. The principal charitable foundations are the *Casa de Caridad*, or House of Industry, the Hospital General, dating from 1401, and the Foundling Hospital. The *Montes de Piedad* are, in fact, mutual benefit societies; and that of Nostra Señora de la Esperanza has this peculiarity, that loans on deposits are made without interest to necessitous persons, thousands of whom yearly avail themselves of its advantages. The principal civic and commercial buildings are the *Casa Consistorial*, a fine Gothic hall, the *Lonja*, or Exchange, dating from 1383, and the *Aduana*, or Custom-house, built in 1792. At the seaward end of the Rambla is a large ancient structure, the *Atarazanas*, or Arsenals, which was finished about 1243. A portion of it was recently taken down to give a better view to the promenade. Remains of the former royal state of Barcelona are found in the Palacio Real of the kings of Aragon, and the Palacio de la Reina. At the highest part of the city, in the Calle del Paradis, are some magnificent columns, and other Roman remains, which, however, are hidden by the surrounding buildings.

The inhabitants of Barcelona are not only an intelligent and industrious, but a gay and pleasure-loving people. Means of public recreation are abundantly supplied. There are no fewer than fourteen theatres of more or less pretension, the two most important being the Teatro Principal and the Teatro del Liceo. The latter is a very fine building, originally erected in 1845 on the site of a convent of Trinitarian monks, and capable of containing 4000 spectators. A striking feature in Barcelona society is the development of social life; and the number of restaurants and similar places of evening resort is very great. A pleasant promenade is furnished not only by the Rambla but by the Muralla del Mar, or sea-wall, which was largely due to the marquis de la Mina, and is now undergoing extensive alteration by the reclaiming of a strip of land from the port.

Barcelona has long been the industrial and commercial centre of Eastern Spain—a pre-eminence which dates from the 12th and 13th centuries. It was the rival of Genoa and Venice, and in renown its hardy mariners were second to none. The origin of the famous code of maritime laws known as the *Consolado del mar* is usually, though not with absolute certainty, ascribed to its merchants; and it is pretty well established that they were the first to employ the method of marine insurance. We find them at an early period trading not only with the ports of the Mediterranean, but with the Low Countries and England, on the one hand, and with Constantinople and Damascus, Egypt and Armenia, on the other,—entering into treaties with kings and magistracies, and establishing in all important places consuls to look after their interests. The prosperity so deeply rooted continued through numerous vicissitudes till the emancipation of the Spanish American colonies, when a comparative decline set in. This, however, proved only temporary, and, in spite of the disastrous consequences of the French invasion, and the various revolutions of the country since then, Barcelona has no need to look back with regret to the past. A great variety of

industries are now carried on—the most important being the spinning and weaving of wool, cotton, and silk. Of the numerous guilds that were anciently formed in the city an interesting list is to be found in Capmany. It carries on a large shipping trade. In 1872 between 700 and 800 foreign vessels, with a tonnage of 360,000 tons, discharged their cargoes in the port. Of these 160 were British. The imports from the colonies are sugar, cotton, tobacco, rum, wax, dye-wood, &c.; machinery, coals, coke, cotton, wool, thread, and other stuffs, are brought from England; articles of silk, chemical preparations, pastes and flours of all sorts, objects of fashion, wines and liquors, from France; petroleum, cotton, and staves from North America; cotton from the Brazils and Smyrna; hides from the River Plate; salt fish from the North Sea. The export trade is not so extensive, consisting largely of fruits and vegetables, oil, silk, wines, salt, &c. The so-called port of Barcelona was at first only an open beach, slightly sheltered by the neighbouring hills, but at an early period the advantage of some artificial protection was felt. In 1438 we find Don Alphonso V. granting the magistracy a licence to build a mole; and in 1474 the *Moll de Santa Creu* was officially commenced. Long after this, however, travellers speak of Barcelona as destitute of a harbour; and it is only in the 17th century that satisfactory works were undertaken. Down to a very recent period all the included area was shut off from the open sea by a sand-bank, which rendered the entrance of large vessels impossible. An extension of the former mole, and the construction of another from the foot of Montjuich, have embraced a portion of the sea outside of the bank, and a convenient shelter is thus afforded for the heaviest men of war. The depth in this part is about 40 feet, while within the sandbank it is from 18 to 20. Barcelona is well supplied with inland communication by rail, and the traffic of its own streets is largely facilitated by tramway lines running from the port as far as Garcia.

According to traditions preserved by the Roman writers, Barcelona owed its origin, or at least its first importance, to the Carthaginians under Hamilcar Barca, after whom it was called *Barcino*. It received a Roman colony, and was known by the name of *Faventia*. After having shared in the various vicissitudes of the barbaric invasions, it became the capital of a dukedom under Louis the Pious, and not long after began to give the title of count to a family that soon made itself independent. In 985 the city was captured by the Moors, but not long after it was recovered by Count Borell. In 1151 Raymund Berenguer married the daughter of Ramiro II. of Aragon, and thus the countship of Barcelona was united to that kingdom by his son. From the successive princes of the line the city received many privileges. In 1640 Barcelona was the centre of the Catalonian rebellion against Philip IV., and threw itself under French protection. In 1652 it returned to its allegiance, but was captured by the duke of Vendôme in 1697. At the peace of Ryswick, in the same year, it was restored to the Spanish monarchy. During the War of the Succession Barcelona adhered to the house of Austria. The seizure of Montjuich in 1705 and the subsequent capture of the city by the earl of Peterborough formed one of his most brilliant achievements. In 1714 it was taken after an obstinate resistance by the duke of Berwick in the interests of Louis XIV., and at the close of the war was reluctantly reconciled to the Bourbon dynasty. At the commencement of Bonaparte's attempt on the liberty of Spain, the French troops obtained possession of the fortress, and kept the city in subjection. Since then it has shared in most of the revolutionary movements that have swept over Spain, and has frequently been distinguished by the violence of its civic commotions. By the census of 1857 the population of the city amounted to 180,014, and by an enumeration in 1864 the city and suburbs were found to contain 252,000 persons. (See *Manifestacion de muichos relevantes servicios de Barcelona*, Barcelona, 1697; Capmany, *Memorias historicas sobre Barcelona*, 1779-92; Chantreau, *Lettres de Barcelonne*, 1793; Hare, *Wanderings in Spain.*)

BARCLAY, Alexander, an English poet, was born probably about 1476. His nationality has been matter of much literary dispute, but the evidence on the whole seems to point to the conclusion that, though he spent the greater part of his life in England, he was a native of Scotland. The place of his education is equally doubtful; he studied at one of the great English universities, but at which has not yet been settled by his biographers. He received a benefice from the provost of Oriel College, Oxford, and it might therefore be inferred that he had been a student at that place. But Oxford is nowhere referred to in his writings, whereas Cambridge is mentioned once. He appears to have travelled on the Continent after completing his university course, and on his return received an appointment as chaplain in the collegiate church at Ottery St Mary in Devonshire. He afterwards became a Benedictine monk of the monastery of Ely, and at length assumed the habit of St Francis at Canterbury. Having survived the dissolution of the monasteries, he became successively vicar of Much-Badew in Essex, and, in 1546, of Wokey in Somersetshire; and a few months before his death he was presented by the dean and chapter of Canterbury to the rectory of All-Saints in Lombard Street. As he retained some of his preferments in the reign of Edward VI., it is presumed that he must have complied with the changes of the times. He died at an advanced age in the year 1552, and was interred at Croydon. Barclay wrote at a period when the standard of English poetry was extremely low; and, as excellence is always comparative, this circumstance may partly enable us to account for the high reputation which he enjoyed among his contemporaries. At the same time his best work, being a comprehensive and easily understood satire on the manners of the times, naturally acquired a wide popularity, and was extensively read. The title given to it was the *Ship of Fooles*, and it was first printed by Pinson in 1509. The original design, and many of the details, were derived from Sebastian Brandt, a civilian of Strasburg, who in 1494 published a poem entitled *Das Narren Schyff*, which was so well adapted to the taste of the age that a Latin and a French version appeared in 1497, and another French version in 1498. Barclay professes to have translated "oute of Laten, Frenche, and Doche;" but to the original cargo he has added many fools of English growth. Under the representation of a ship freighted with fools of various denominations, the poet exposes the prevalent vices and follies of the age; and although, as Warton remarks, the poem is destitute of plot and the voyage of adventures, the general design was found to possess many attractions. The work is of considerable importance, as giving a clear though by no means pleasing picture of English society and lower class life in the time of Henry VIII., and also as marking a stage in the progress of the English language. Barclay's vocabulary is essentially that of the people. His other works are—*The Castell of Laboure*, 1506; *The Mirrour of Good Manners*, translated from the poem of Mancini *De quatuor Virtutibus; The Egloges;* a version of Sallust; an *Introduction to Write and to Pronounce Frenche*; and some small pieces. A catalogue of all these, with full notice of the little that is known concerning Barclay, and ample bibliographical information, is supplied by Mr Jamieson in the introduction to his edition of the *Ship of Fools*, Edin., 1874.

BARCLAY, JOHN, a distinguished scholar and writer, was born, January 28, 1582, at Pont-à-Mousson, where his father William Barclay (see below) was professor of civil law. Educated at the Jesuits' college, he gave evidence of remarkable ability at an early age, and was only nineteen when he published a commentary upon the *Thebais* of Statius. The Jesuits were naturally desirous that he should enter their order, but to this both himself and his father were averse. The jealous enmity of the order was roused against them in consequence of this refusal, and in 1603 both left France and crossed over to England. In the following year they returned and settled at Angers, where Barclay's father had been appointed professor of law. Soon after the death of his father in 1605, Barclay appears to have married, and to have settled in London, where in 1606 he published the second part of his *Satyricon*, the first part having appeared on his previous visit to England. In 1610 he edited an important treatise left by his father, *De Potestate Papæ*, which involved him in controversy with the famous Cardinal Bellarmin. In 1614 appeared the wittiest and most interesting part of the *Satyricon*, entitled *Icon Animorum*, which gives a critical survey of the varied manners and characteristics of the several European nations. It has been frequently reprinted. In 1616, after a short stay in Paris, he proceeded to Rome, where he continued to reside till his death on 12th August 1621. His romance, *Argenis*, was passing through the press at the period of his death, and it appeared in the course of the same year. Barclay, from what reason is not apparent, failed to attain the position to which his talents seemed fairly to entitle him. His reputation as a writer and scholar was remarkably high among his contemporaries. Grotius and others have lavished praises on the purity and elegance of his Latin style; his romance was extremely popular; and some of his Latin poems are very happy. The idea of the *Satyricon*, one of his two extensive compositions, is borrowed from Petronius; in the details, however, the work fortunately does not follow that author so closely. It was very extensively read, and has passed through several editions. The *Argenis*, a long Latin romance, sometimes looked on as a political allegory, was very popular. It is said to have been warmly admired by Richelieu and Leibnitz, while Cowper, Disraeli, and Coleridge speak of it in terms of high admiration. The value that was put upon it by Barclay's contemporaries and immediate successors may be gathered from the critical estimate of it given in the *Vita Barclaii*, prefixed to later editions of the work. "*Habet enim*," says the anonymous writer of the life, "*heroicum Tullii vigorem, Laconismum et politicam Taciti, Livii antiquitatem, flosculos puros Petronii, sales fabulosos Nasonis, poeticam Maronica vix inferiorem.*" There have been numerous editions of the book, which has been translated into almost every European language.

BARCLAY, JOHN, M.D., an eminent anatomist, was born in Perthshire in 1760, and died at Edinburgh in 1826. After the usual routine of parochial education, he completed his academical course at the United College of St Andrews. He subsequently studied divinity there, and was licensed as a preacher by the Presbytery of Dunkeld. Having repaired to Edinburgh in 1789, as tutor to the family of Sir James Campbell of Aberuchill, he began to give his attention to the study of medicine, and particularly to human and comparative anatomy. He became assistant to Mr John Bell, and took the degree of M.D. in 1796, after having defended an inaugural dissertation, *De Anima seu Principio Vitali*, a subject which occupied his maturer powers towards the close of his life. Immediately after his graduation, he repaired to London, and studied for some time under Dr Marshall, at that time a very distinguished teacher of anatomy in the metropolis. Soon after his return to Edinburgh, he commenced his lectures on anatomy in November 1797, and speedily attracted an audience, which increased considerably in numbers until the period of his retirement, a short time before his death.

Of Barclay's professional writings, the earliest, we believe, was the article PHYSIOLOGY, contributed to the third edition of this work. In 1803 he attempted a reform in the language of anatomy, with a view to render it more accurate and precise,—a task for which his acquirements as a classical scholar rendered him peculiarly well qualified. Although the *Nomenclature* which he published in that year has not been generally adopted, the profession acknowledged the importance of the object which he had in view, as well as the talent and learning with which it was executed. In 1808 he published his *Treatise on the Muscular Motions of the Human Body*, and in 1812 his *Description of the Arteries of the Human Body*, a work displaying much acute observation and laborious research, which may be considered the most practically useful of all his writings. His last publication, completed only a few years before his death, was *An Inquiry into the Opinions, Ancient and Modern, concerning Life and Organization*, a work replete with learning and sound original criticism. His introductory lectures published after his death contain a valuable abridgment of the history of anatomy.

BARCLAY, JOHN, founder of a small sect in the Scotch Church called Bereans or Barclayites, was born in Perthshire in 1734, and died at Edinburgh in 1798. He graduated at St Andrews, and after being licensed became assistant to the parish minister of Errol in Perthshire. He developed some very peculiar views, which led to a difference with the minister; and in 1763 he left and was appointed assistant to Mr Dow of Fettercairn. In this parish he became very popular, but his opinions, whether as expounded from the pulpit, or as set forth in a paraphrase of some Psalms which he published, failed to give satisfaction to his Presbytery. In 1772 he was rejected as successor to Mr Dow, and was even refused by the Presbytery the testimonials requisite in order to obtain another living. The refusal of the Presbytery was sustained by the General Assembly, and Mr Barclay thereupon left the Scotch Church. He preached in Edinburgh, London, Bristol, and other places, but with no great success. Neither his writings, which were collected in three volumes, nor the sect formed by him, are of much importance. His adherents were called Bereans, because they regulated their conduct as the inhabitants of Berea are said to have done, by diligently searching the Scriptures (Acts xvii. 11).

BARCLAY, ROBERT, one of the most eminent writers belonging to the Society of Friends, or Quakers, was born in 1648 at Gordonstown in Morayshire. He was sent to finish his education in Paris, and it appears he was at one time inclined to accept the Roman Catholic faith. In 1667, however, he followed the example of his father, Colonel Barclay of Urie, and joined the recently formed Society of Friends. He was an ardent theological student, a man of warm feelings and considerable mental power, and he soon came prominently forward as the leading apologist of the new doctrine. His greatest work, *An Apology for the True Christian Divinity*, was published in Latin in 1676, and was an elaborate statement of the grounds for holding certain fundamental positions, laid down in the *Theses Theologicæ* which had been put forward in the preceding year. The most prominent of the *Theses* was that bearing on Immediate Revelation, in which the superiority of this Inner Light to Reason or Scripture is sharply stated. Barclay experienced to some extent the persecutions inflicted on the new society, and was several times thrown into prison. He died in 1690 at the early age of forty-two. His *Apology*, which is still the most important manifesto of the Quaker society, was translated by himself into English in 1678. Translations of it into foreign languages have also appeared.

BARCLAY, William, LL.D., a writer on civil law, was born in Aberdeenshire in the year 1541. He spent the early part of his life, and much of his fortune, at the court of Mary queen of Scots, from whose favour he had reason to expect preferment. In 1573 he went over to France, and at Bourges began to study civil law under the famous Cujas. He continued some years in that seminary, where he took his doctor's degree; and was soon after appointed professor of civil law in the university of Pont-à Mousson, recently founded by the duke of Lorraine. The prince afterwards made him counsellor of state and master of requests. In the year 1581 Barclay married Anne de Malleville, a French lady. Their son was the celebrated John Barclay, author of the *Argenis*. This youth the Jesuits would gladly have received into their society; but his father refused his consent, and thereby incurred their bitter enmity. He was compelled to leave France, and returned to Britain, where King James offered him a considerable preferment, provided he would become a member of the Church of England. He would not accept the post on this condition, and went back again to France in 1604. Soon after his arrival he was appointed first professor of the civil law in the University of Angers, where he died the year following, and was buried in the Franciscan church. Barclay was a man of considerable ability, and his legal writings are still valued. In his political opinions he was directly opposed to his illustrious countryman Buchanan, and was a strenuous defender of the rights of kings; his own speculations on the principles of government are best known to some from an incidental confutation by Locke, in his *Treatises on Government*. His most important writings were--

De Regno et Regali Potestate, adversus Buchananum, Brutum, Boucherium, et reliquos Monarchomachos, libri sex, Paris, 1600, 4to; *In Titulum Pandectarum de Rebus creditis et Jurejurando Commentarii*, Paris, 1605, 8vo; *De Potestate Papæ; an et quatenus in Reges et Principes seculares jus et imperium habeat: Liber posthumus*, Mussiponti, 1610, 8vo. This work was translated into French, and an English version is printed with the treatise of Sheldon, *Of the Lawfulness of the Oath of Allegiance*, Lond. 1611, 4to. Barclay's two treatises, *De Regno* and *De Potestate Papæ*, have repeatedly been printed in the same volume: Hanover, 1612, 8vo; Hanover, 1617, 8vo.

BARCLAY DE TOLLY, Michael, a Russian prince and general, highly distinguished in the wars with Napoleon, was born in Livonia in 1759. He was a descendant of the old Scotch family of Barclay, a branch of whom had settled in Russia in the 17th century. He was adopted by General Vermoulen, and entered a Russian cuirassier regiment when very young. In 1788 and 1789 he served against the Turks, and in the following years against the Swedes and Poles. In 1806, when Russia took up arms against Napoleon, he commanded the advanced guard at the battle of Pultusk. At Eylau he lost an arm, and was promoted to the rank of lieutenant-general. In 1808 he commanded against the Swedes, and in 1809 by a rapid and daring march for two days over the ice he surprised and seized Umeo. In 1810 he was made minister of war, and retained the post till 1813. There was very keen opposition to the appointment of a foreigner as commander-in-chief, and after the defeat of Smolensk, the outcry was so great that he resigned his office and took a subordinate place under the veteran Kutusoff. On the death of the latter he was reappointed to the supreme command, and fought at the battles of Bautzen, Dresden, and Leipsic. He was unable to bring up his forces in time for the battle of Waterloo, but marched into France and took part in the occupation of Paris. He was rewarded for his services by being made prince and field-marshal. He died in 1818 at Insterburg, in Prussia, while on his way to the Bohemian baths.

BAR-COCHEBAS, or Bar-cochab (*Son of a Star*), a celebrated Jewish leader in the insurrection against Hadrian, 131–135 A.D., whose real name was Simeon. The events of his life belong to the history of the Jews.

BARD, from the Welsh *bardd*, is the name applied to the ancient Celtic poets, though the word is sometimes loosely used as synonymous with poet in general. So far as can be ascertained, the title *bards*, and some of the privileges peculiar to that class of poets, are to be found only among Celtic peoples. The name itself is not used by Cæsar in his account of the manners and customs of Gaul and Britain, but he appears to ascribe the functions of the bards to a section of the Druids, with which class they seem to have been closely connected. Later Latin authors, such as Lucan (*Phar.*, p. 447), Festus (*De Verb. Sign. s. v.*), and Ammianus Marcellinus (bk. xv.), used the term *Bardi* as the recognized title of the national poets or singers among the peoples of Gaul and Britain. In Gaul, however, the institution soon disappeared; the purely Celtic peoples were swept back by the waves of Latin and Teutonic conquest, and finally settled in Wales, Ireland, Brittany, and the north of Scotland. There is clear evidence of the existence of bards in all these places, though the known relics belong almost entirely to Wales and Ireland, where the institution was more distinctively national. In Wales they formed an organized society, with hereditary rights and privileges. They were treated with the utmost respect, and were exempt from taxes or military service. Their special duties were to celebrate the victories of their people, and to sing hymns of praise to God. They thus gave poetic expression to the religious and national sentiments of the people, and therefore exercised a very powerful influence. The whole society of bards was regulated by laws, said to have been first distinctly formulated by Hywell Dha, and to have been afterwards revised by Gruffydd ap Conan. At stated intervals great festivals were held, at which the most famous bards from the various districts met and contended in song, the umpires being generally the princes and nobles. Even after the conquest of Wales, these festivals, or *Eisteddfodau*, as they were called, continued to be summoned by the English sovereigns, but from the reign of Elizabeth the custom has been allowed to fall into abeyance. They have not since been summoned by royal authority, but have been revived, and are held regularly at the present time. In Ireland also the bards were a distinct class with peculiar and hereditary privileges. They appear to have been divided into three great sections: the first celebrated victories and sang hymns of praise; the second chanted the laws of the nation; the third gave poetic genealogies and family histories. The Irish bards were held in high repute, and frequently were brought over to Wales to give instruction to the singers of that country.

See Ed. Jones, *Relics of the Welsh Bards*, 1784; Walker, *Memoirs of the Irish Bards*, 1786; Owen Jones, *Myvyrian Archæology of Wales*, 3 vols., 1801–7; W. F. Skene, *Four Ancient Books of Wales*, 2 vols., 1868.

BARDESANES, or Bar Deisan, a celebrated Gnostic, was a native of Edessa in Mesopotamia, and appears to have flourished during the reign of Marcus Aurelius. Very little is known of his life. He is said to have held a disputation with Apollonius, a philosopher in the train of Lucius Verus, and he is known to have written against the Marcionite and other heresies. There is considerable doubt whether he was ever a disciple of Valentinus, but it is acknowledged that he never ceased to belong to the Christian church. However seriously his principles, if rigidly interpreted, might conflict with the doctrines of Christianity, he did not regard himself as opposed to that faith, and he was generally considered one of its best defenders. He was especially famed for his hymns, fragments of which are still extant. Of his other works

there seems to remain only a treatise *On Fate*, a portion of which was preserved by Eusebius (*Prep. Evan.*, vi. 10), while the whole has been printed from a Syriac MS. with English translation by Cureton (*Spicilegium Syriacum*, Lond. 1855). The system of Bardesanes, so far as it can be gathered from the scanty notices of other writers, had many points in common with that of Valentinus, but shows to an almost greater extent the influence of Oriental mysticism and imagery. He begins, as do all the other Gnostics, with postulating the existence of the Unknown God or Father, the ground of all the forms of being. Alongside of God, and co-existing with Him,—in fact, His necessary shadow,—is vague, unformed, eternal, and uncreated Matter. From this dualism springs the possibility of evil in the universe. Evil is not, indeed, correlative and equally necessary with God, but arises from matter. The Eternal Father, through union with His everlastingly produced, but shadowy companion, brings forth the Son, from whose union with the Holy Spirit (*Sophia*) spring the elements. The combinations of the productive and receptive agents are called *syzygies*, and of them there are seven. Bardesanes, who had deeply studied the Chaldean astrology, seems to have discussed at great length the influence of the stars on human action. He vindicated for man, what may, with some stretch of language, be termed a *transcendental* freedom. His followers were distinguished by the strange opinion they entertained with regard to the body of Christ, which they held to be only phenomenal, not real. Besides the notices of Bardesanes to be found in general works on Gnosticism,—as those of Baur, Matter, Lipsius, and Mansel,—the following may be consulted:—Hahn, *Bardesanes Gnosticus Syrorum primus hymnologus*, 1819; Hilgenfeld, *Bardesanes, der letzte Gnostiker*, 1864.

BARDILI, CHRISTOPH GOTTFRIED, a German metaphysician, distinguished by his opposition to the system of Kant, was born at Blaubeuren in Würtemberg, in 1761, and died at Stuttgart in 1808. Of his numerous works the principal is his *Elements of Logic* (*Grundriss der ersten Logik*, Stuttgart, 1800). His system has had but little influence in Germany, the celebrated Reinhold being the only adherent of any importance. Yet in some respects his ideas opened the way for the later speculations of Schelling and Hegel. He dissented strongly from the Kantian distinction between matter and form of thought, and urged that philosophy should consider only thought in itself, pure thought, which is the ground or possibility of being. The fundamental principle of thought and criterion of certitude was, according to him, the law of identity; logical thinking was real thinking. The matter upon which thought operated was in itself indefinite and unformed, a mere ἄπειρον, which was rendered definite or took determinate forms through the action upon it of thought. Bardili, however, worked out his fundamental idea in an abstract, one-sided manner. Thought, as conceived by him, had no power of development in it, and ultimately reduced itself to a species of arithmetical computation. (See on his system the notices in Michelet, *Geschichte der letzten Systeme*, Bd. i., and Erdmann, *Versuch einer Geschichte d. neu. Phil.*, Bd. iii. pt. i.)

BARDSEY (*i.e.* Bard's Island), or in Welsh YNYS ENLLI, the Island of the Current, is situated at the northern extremity of Cardigan Bay. It is 2½ miles long by 1 broad, with an area of about 370 acres, of which one-third is hilly. The island produces both barley and oats. On the S.E. side there is a harbour which admits vessels of 40 tons. On the north side are the ruins of St Mary's Abbey, said to have been founded by Cadfan in 516, which afforded refuge to great numbers of fugitives during the 7th century. The lighthouse has a fixed light 129 feet above high water, in lat. 52° 45′ N., long. 4° 47′ W.

BARDWÁN (sometimes spelled Burdwan), a division or commissionership in India under the Lieutenant-Governor of Bengal, comprising the districts of Bardwán, Húglí with Howrah, Midnapur, Bánkurá or West Bardwán, and Bírbhúm, lies between 23° and 25° N. lat. and between 86° and 89° E. long. It is bounded on the N. by the district of the Santál Parganás in the Bhágalpur division, and Murshidábád in the Rájsháhí division; on the E. by the Presidency districts of Nadiyá, and the 24 Parganás; on the S. by the Bay of Bengal, and on the W. by the native tributary state of Morbhanj, and the district of Mánbhúm in the Chhotá Nágpur division. In 1872 Bardwán division contained an area of 12,719 square miles, with a population of 7,286,957, inhabitating 25,842 towns and villages, and 1,468,791 houses; persons per square mile, 573; villages or townships per square mile, 2·03; houses per square mile, 115; persons per village, 282; and persons per house, 5. The census of 1872 classifies the population of the Bardwán division as follow:—Hindus—males, 3,051,967; females, 3,164,093; total, 6,216,060, or 85·3 per cent.: Mahometans—males, 450,103; females, 479,288; total, 929,391, or 12·8 per cent.: Christians—males, 2352; females, 2053; total, 4405, or ·1 per cent.: total—males, 3,572,108, or 49 per cent.; females, 3,714,849, or 51 per cent.; grand total, 7,286,957.

BARDWÁN, an important district in the division of the same name, under the Lieutenant-Governor of Bengal, situated between 23° 53′ and 22° 46′ N. lat., and between 88° 39′ and 86° 52′ E. long. It is bounded on the N. by the districts of Bírbhúm and Murshidábád, from which it is separated by the River Ajai; on the E. by the districts of Nadiyá and Húglí, the River Bhágirathí separating it from the former; on the S. by the districts of Húglí and Midnapur; and on the W. by the districts of Bánkurá and Mánbhúm. For fiscal purposes the Board of Revenue returns its area at 3150 square miles:—cultivated, 2810; cultivable, but not cultivated, 190; and uncultivable, 150. The census of 1872 gives the police area at 3523 square miles, with a population of 2,034,745 souls, inhabitating 5191 villages, and residing in 435,416 houses. Persons per square mile, 578; per village, 392; per house, 4·7. Hindus number 1,679,363, or 82·5 per cent.; Mahometans, 348,024, or 17·1 per cent.; Christians, 890, or ·1 per cent.; and persons of unspecified religion, 6468, or ·3 per cent.

Bardwán is a flat plain, and its scenery is uninteresting. Chief rivers—the Bhágirathí, Dámodar, Ajai, Bánká, Kunur, and Kharí, of which only the Bhagirathí is navigable by country cargo boats throughout the year. Agricultural products—paddy, indigo, pulses, oil-seeds, sugar-cane, potatoes, tobacco, wheat, onions, garlic, pumpkins, melons, cucumbers, and vegetables of various kinds. Bardwán district is one of the best cultivated in Lower Bengal. Minerals—iron, copper, lime and sandstone, and above all, coal. The greater portion of the coal-bearing rocks, known as the Dámodar or Ráníganj field, is enclosed between the Rivers Dámodar and Ajai, and lies between 23° 35′ and 23° 45′ N. lat., and 86° 40′ and 87° 15′ E. long., at a distance of from about 120 to 160 miles north-west from Calcutta. The beds are composed of coarse and fine sandstones and felspathic coal-seams, the latter being frequently continuous over considerable areas. Those known as the Lower Dámodars are coarse conglomerates, with white sandstones and numerous coal-seams of very irregular character. The working of the Ráníganj coal (which at present, 1874, is included within the Bardwán district) dates from 1774, when a company was formed by several English gentlemen for the purpose of mining the collieries; and in the following year 91 tons of Bardwán coal were despatched to Calcutta. In 1860, 49 collieries were worked, chiefly conducted with European capital, and yielded a total out-turn of 313,300 tons. In 1868 the out-turn of the whole coal-field exceeded 500,000 tons. There are now 44 coal-mines at work within the Bardwán district, of which 19 mines turn out more than 10,000 tons of coal apiece per annum. In the larger and better mines coal is raised by steam from pits and galleries. In the smaller mines or workings coal is raised by hand labour from open quarries. In the Ráníganj coal-field 61 steam engines, with an aggregate of 867 horse-power, are at work. Only one seam (or set of seams) of a less thickness than 8½ feet is

worked, and the average thickness of the seams at the Ránígaṅj mines is about 15 or 16 feet. The pits are mostly shallow, very few being more than 150 feet deep. The Bengal Coal Company, with its mines at Ránígaṅj and westwards, is alone able to raise more than 200,000 tons of coal annually. Silk and cotton cloth, brass utensils, silver and gold ornaments, and indigo, are the principal manufactures of the district. Three indigo factories in Bardwan are conducted with European capital. Articles of trade consist of rice, tobacco, pulses, wheat, oil-seeds, jute, sugar, salt, English and country made cloths, cotton, molasses, timber, and coal. In 1790 the total revenue of the Bardwán district amounted to £508,093, in 1820 to £458,321, and in 1870 (after transfers of a large part of its area to adjoining districts) to £388,773. The expenditure in 1797 amounted to £11,213, in 1820 to £17,338, and in 1870 to £63,435. The land tax is the principal source of revenue, which amounted in 1790 to £503,272, in 1850 (from a reduced area) to £309,618, and in 1870 to £305,806. For the protection of person and property Government maintained in 1871 a regular constabulary force 682 strong, at a total cost of £11,622 a year, besides 11,052 men of the village watch possessing service lands or paid by the villagers. Bardwán contained 939 schools in 1871–72, attended by 21,926 pupils, and costing £4328 annually to the state. For administrative purposes the district is divided into six magisterial subdivisions—Bardwán, Kálná, Kátwá, Bud-bud, Ránígaṅj, and Jahánabád, with 22 police circles. Exclusive of the Bardwán city described below, there are seven towns in the district containing a population of more than 5000 souls. They are also municipalities, and are as follows:—1. Kálná—population: Hindus, 22,463; Mahometans, 3557; Christians, 38; others, 1278; total, 27,336: municipal income in 1872, £1185; expenditure, £980; rate of taxation, 10⅝d. per head. 2. Syámbázár—population: Hindus, 19,341; Mahometans, 294; total, 19,635: municipal income, £276; expenditure, £224; rate of taxation, 3⅝d. per head. 3. Ránígaṅj—population: Hindus, 17,927; Mahometans, 1473; Christians, 178; total, 195,78: municipal income, £871, 12s.; expenditure, £871, 12s.; rate of taxation, 3d. per head. 4. Jahánábád: Hindus, 10,222; Mahometans, 3187; total, 13,409: municipal income, £238, 18s.; expenditure, £250, 14s.; rate of taxation per head, 4¼d. 5. Báli—population: Hindus, 8150; Mahometans, 669; total, 8819: municipal income, £173, 4s.; expenditure, £214, 4s.; rate of municipal taxation, 4⅝d. per head. 6. Kátwá—population: Hindus, 6817; Mahometans, 1131; Christians, 15; total, 7963: municipal income, £513, 14s.; expenditure £513, 14s.; rate of taxation, 1s. 3¼d. per head. 7. Dainhát—population: Hindus, 7389; Mahometans, 173; total, 7562: municipal income, £398, 8s.; expenditure, £386, 8s.; rate of taxation, 1s. 0⅝d. per head. The East Indian Railway and the Grand Trunk road leading to the North-Western Provinces pass through the district, which has also fifteen other roads communicating with the neighbouring districts. The climate of Bardwán was considered a few years back to be the healthiest in Bengal. But an epidemic fever broke out about 1867, and is still (1874) raging in the district. It causes havoc and depopulation among the cultivating classes. The Mahárájá of Bardwán, one of the largest landholders in Bengal, has an income estimated at £400,000 to £500,000 sterling a year. Bardwán district was acquired by the East India Company under the treaty with Nawáb Mir Kásim in 1760, and confirmed by the Emperor Sháh Alam in 1765. The land revenue was fixed in perpetuity with the zamíndárs in 1793.

Bardwán, the principal town of the district of the same name, situated on the route from Calcutta to Benares, and a station on the East Indian Railway, lies in 23° 14′ 15″ N. lat., and 87° 53′ 57″ E. long. Jacquemont formerly described Bardwán town "as consisting of an assemblage of crowded suburbs, of wretched huts, with walls of mud, and covered with thatch, having no temples of striking aspect, and few handsome houses." At the present time Bardwán is a well-built, busy town, with commodious streets, dotted with large tanks, and surrounded by luxuriant gardens. The Mahárájá's palaces are handsome buildings, furnished in the English style, with elegant mirrors and nick-nacks from Paris, and some tolerable oil paintings. Bardwán forms the headquarters of the civil authorities of the division and district, consisting of the commissioner, the judge, magistrate, and collector, and their European and native assistants. In 1814 the town contained a population estimated at 53,927 souls; and in 1872, 32,321. Details of population in 1872:—Hindus, 22,013; Mahometans, 9927; Christians, 223; persons of unspecified religion, 158; total, 32,321. Municipal income in 1871, £5450; expenditure, £5450; rate of taxation, 3s. 4⅝d. per head. In 1695 Bardwán was besieged by a rebel chief of the Great Mughul. The city soon fell into the hands of the besiegers, the Rájá was slain in battle outside the walls, and the ladies of his family committed suicide, to avoid falling into the hands of the conquerors. The present Mahárájá is a well-educated, liberal-minded man. He maintains a great public school in the town at his own cost, and is ever forward with help in time of distress or famine, as in 1866 and 1874.

BAREGES, a small town situated between two mountain chains in the department of Hautes Pyrénées in France, about 25 miles from Bagnères de Bigorre. It is celebrated for its warm sulphurous springs, first brought into notice by the visit of Madame du Maintenon in 1676, the temperature of which varies from 88° to 111° Fahr. The benefit of the waters is granted to the army at the expense of the Government, which erected a bath-house in 1864. During the winter the town is so exposed to avalanches that only a few of the residents remain. The town gives its name to a silk-fabric (barège) which is principally manufactured in Bagnères de Bigorre.

BARELÍ, or Bareilly, a district of British India in the Rohilkhand division, under the jurisdiction of the Lt.-Governor of the North-Western Provinces, situated between 28° 2′ and 29° 2′ N. lat., and 79° 2′ 30″ and 80° 13′ 15″ E. long. It is bounded on the N. by Kumáon district and the independent state of Nepál; on the E. by a portion of the district of Sháhjahánpur, and the district of Lakhimpur in Oudh; on the S. by the districts of Budáon and Sháhjahánpur; and on the W. by the native state of Rámpur and Budáon. Barelí is a level country, watered by many streams, the general slope being towards the south. The soil is fertile and highly cultivated, groves of noble trees abound, and the villages have a neat, prosperous look. A tract of forest jungle, called the *Tarái*, stretches along the extreme north of the district, and teems with large game, such as tigers, bears, deer, wild pigs, &c.

The River Sardá or Ghagrá forms the eastern boundary of the district, and is the principal stream. Next in importance is the Rámgangá, which receives as its tributaries most of the hill torrents of the Kumáon mountains; the principal ones being the East Bahgúl, Nakatiyá, Deuraniyá, Saukhá, Sidhá, Dujaurá, Kichaha, West Bahgúl, Bhakrá, Dhakrá, and Dhúrá. The Deohá is another great drainage artery, and receives many minor streams. The Gomatí or Gúmtí also passes through the district. Barelí district has an area of 2976·70 square miles, of which 1845·28 square miles are under cultivation; 727·65 square miles are cultivable, but not actually under cultivation; 25·16 square miles are held revenue free; and 378·60 square miles are returned as uncultivable waste.

The census of 1872 takes the area at 2982 square miles, and returns the population at 1,507,139 souls, inhabiting 3548 villages or townships, and 296,441 houses; density of population per square mile, 505; villages or townships per square mile, 1·2; persons per village or township, 425; houses per square mile, 99; persons per house, 5. Of the total population, 1,197,583, or 79·5 per cent., are Hindus; 308,682, or 20·5 per cent., Mahometans; and 536 Christians, or others of unspecified religion. The Mahometans are chiefly the descendants of Yusafzaí Afgháns, called the Rohillá Patháns, who settled in the country about the year 1720. The Rohillás were formerly the ruling race of the tract of country called Rohilkhand, and are men of a taller stature, a fairer complexion, and a more arrogant air than the general inhabitants of the district. Bishop Heber has described them as follows:—"The country is burdened with a crowd of lazy, profligate, self-called sawárs (cavaliers), who, though many of them are not worth a rupee, conceive it derogatory to their gentility and Pathán blood to apply themselves to any honest industry, and obtain for the most part a precarious livelihood by sponging on the industrious tradesmen and far-

mers, on whom they levy a sort of blackmail, or as hangers on to the few wealthy and noble families yet remaining in the province. These men have no visible means of maintenance, and no visible occupation except that of lounging up and down with their swords and shields, like the ancient Highlanders, whom in many respects they much resemble." The Rohillás, after fifty years' precarious independence, were subjugated in 1774 by the confederacy of British troops with the Nawáb of Oudh's army, which formed so serious a charge against Warren Hastings. Their territory was in that year annexed to Oudh. In 1801 the Nawáb of Oudh ceded it to the Company in commutation of the subsidy money. During the Sepoy Mutiny of 1857 the Rohillás took a very active part against the English, but since then they have been disarmed. Both before and after that year, however, the Barelí Mahometans have distinguished themselves by fanatical tumults against the Hindus.

The inhabitants of the district are for the most part poor, but their condition has improved under English rule. Sugar and rice, of which large quantities are exported, form the principal agricultural products of the district. Pílíbhít formed an independent district till its incorporation with Barelí in 1842; its rice is celebrated all over the N.W. Provinces. Other agricultural products—wheat, barley, cotton, tobacco, maize, millet, pulses, and fruit. The jungle tract of the district produces fine timber, in which a large trade is carried on. The total revenue of the district for 1870–71 amounted to £246,419, and the civil expenditure to £80,978. By far the greater part of the revenue is derived from the land; the new settlement for thirty years was concluded in 1872. Four towns contain a population of upwards of 5000 souls:—1. Barelí—area, 1280 acres, noticed below. 2. Pílíbhít—area, 433 acres; population, 29,840; municipal revenue (1872), £3291, 6s.; expenditure, £2698, 2s.; rate of taxation, 2s. 2½d. per head. 3. Bisálpur—area, 142 acres; population, 9250; municipal revenue, £282, 8s.; expenditure, £343, 18s.; rate of taxation, 7⅜d. per head. 4. Anwlah—area, 128 acres; population, 11,153; municipal revenue, £183, 2s. 5½d.; expenditure, £224, 15s. 10d.; rate of taxation, 4d. per head. Other minor towns: Farídpur, population, 4940; Saraulí, 4585; Nawábganj, 4418. There are 19 other towns with a population of above 2000. Barelí shows a heavy criminal return, and the police do not appear to be successful in grappling with crime. The regular police consists of a force of 4218 men. In 1872 there were 518 schools in the district, attended by 9265 pupils, besides those attending the university college in the town of Barelí.

Barelí [*Bareilly*], the principal place in the district of the same name, situated on the left bank of the Juá, a tributary of the Western Rámgangá, in N. lat. 28° 23′, E. long. 79° 28′. It is a large town, with a brisk and lucrative commerce, and manufactures consisting principally of house furnitures, such as chairs, tables, &c. Mr Thornton says, that "besides the hands engaged in this branch of handicraft, there are cotton weavers, dressers, and twisters, manufacturers of muslins, and also of silks and brocades, dyers and colour-makers, linen and cloth-plaiters, gold and silver lace-makers, jewellers, goldsmiths, and silversmiths, blacksmiths, coppersmiths, and tinmen, cutlers, armourers, seal-makers and engravers, turners, saddlers, tailors, &c., &c." In 1872 Barelí town contained a population of 102,982, of whom 59,036 were Hindus, 43,463 Mahometans, and 483 of unspecified religion. In 1872 the municipal revenue of the town amounted to £6602, 8s.; expenditure, £7217, 12s.; rate of municipal taxation, 1s. 3⅝d. per head of the population. The municipal revenue is derived from *octroi* duties levied on articles of food brought for sale into the town. The principal institution in the town is the Barelí college, intended as a seat of upper class learning for the surrounding districts of the N.W. Provinces. It is conducted by a staff of efficient professors from England, and its course includes the subjects for degrees in the Calcutta University. In 1872–73 it was attended by 310 pupils. The cost of the college department and upper school amounted to £5836, of which Government contributed £5335.

BARÈRE DE VIEUZAC, Bertrand, one of the most notorious members of the French National Convention, was born at Tarbes in Gascony, September 10, 1755. He was brought up to the profession of the law, and was admitted advocate to the parliament of Toulouse. He wrote several trivial pieces, panegyrics of Louis XVI., Montesquieu, J. J. Rousseau, and others, which obtained prizes from provincial academies, and a dissertation on a Latin inscription which procured him membership of the Academy of Floral Games of Toulouse. Such was the smooth beginning of a career which ultimately became unparalleled for meanness, cowardice, lying, and atrocious cruelty. At the age of thirty he married. Four years later, in 1789, he was elected deputy by his own province to the States-general, which met in May. He had made his first visit to Paris in the preceding year. His personal appearance, his manners, social qualities, and liberal opinions, gave him a good standing among the multitude of provincial wise-heads then thronging into Paris, eager to be the saviours of France, or at least of themselves. He took his place at first with the monarchical party; and his glib pen found occupation in the preparation of various reports, and in editing a journal, the *Point du Jour*, containing reports of the debates of the National Assembly. For a time he formed a connection with the House of Orleans, passing over soon to the republican party. Barère appears to have been wholly free from the restraints of conscience or any guiding principle; his conduct was regulated only by the determination to be on the side of the strongest. After the close of the National Assembly he was nominated one of the judges of the newly-instituted Court of Cassation. In 1792 he was elected deputy to the National Convention for the department of the Hautes Pyrénées. At first he took part with the Girondists; but on the trial of the king he voted, with the Mountain, for the king's death "*sans appel et sans sursis.*" He closed his speech with a sentence which became memorable, "*L'arbre de la liberté ne saurait croître s'il n'était arrosé du sang des rois.*" As the Mountain became the strongest party Barère advanced with it, unscrupulously carrying out its extremest projects, and playing a prominent part in the Reign of Terror. The light-heartedness with which he acted in these awful scenes, the fluency and flippancy of his speeches and reports, procured him the title of the "Anacreon of the Guillotine." He supported Robespierre in his atrocious measure against the Girondists, crawled like a slave at the feet of the "incorruptible" Maximilian till the day of his fall, and then advocated his execution without a hearing. It was Barère who had proposed the decree that no quarter should be given to any English or Hanoverian soldier, which was unanimously adopted. This procured him admission by acclamation to the Jacobin Club, from which he had been previously excluded. The decree, however, remained a dead letter. A few months after the fall of the Convention, proceedings were taken against Barère and his colleagues of the Terror, Collot d'Herbois and Billaud-Varennes, and he was sent to the Isle of Oleron. He was removed to Saintes, and thence escaped to Bordeaux, where he lay in concealment for several years. In 1795 he was elected member of the Council of Five Hundred, but was not allowed to take his seat. When Napoleon Bonaparte was First Consul he was anxious to employ Barère, but Barère refused the overture. It was only for a while. The witling of the Terror became the hireling and the spy of the new tyranny. On the fall of Napoleon, Barère played the part of royalist, but on the final restoration of the Bourbons in 1815 he was banished for life from France, and then withdrew into Belgium and temporary oblivion. After the Revolution of July 1830 he reappeared in France, was reduced by a series of lawsuits to extreme indigence, accepted a small pension assigned him by Louis Philippe (on whom he had heaped

abuse and railing), and died, the last survivor of the Committee of Public Safety, January 15, 1841. Two years after his death appeared *Mémoires de Bertrand Barère*, edited by Hippolyte Carnot and David of Angers. (See Macaulay's article in the *Edinburgh Review*, vol. lxxix., in which the character and career of Barère[1] are discussed with characteristic emphasis and severity.)

BARETTI, GIUSEPPE, an Italian critic of some distinction, was born at Turin in 1716. He was intended by his father for the profession of law, but at the age of sixteen fled from Turin and went to Guastalla, where he was for some time employed in a mercantile house. His leisure hours he devoted to literature and criticism, in which he became expert. For many years he led a wandering life, supporting himself chiefly by his writings. At length he arrived in London, where he remained for a considerable time. He obtained an appointment as secretary to the Royal Academy of Painting, and became acquainted with Johnson, Garrick, and others of that society. He was a frequent visitor at the Thrales'; and his name occurs repeatedly in Boswell's *Life*. In 1769 he was tried for murder, having had the misfortune to inflict a mortal wound with his fruit knife on a man who had assaulted him in the street. Johnson among others gave evidence in his favour at the trial, which resulted in Baretti's acquittal. He died in May 1789. His first work of any importance was the *Italian Library*, London, 1757, a useful catalogue of the lives and works of many Italian authors. The *Lettere Famigliari*, giving an account of his travels through Spain, Portugal, and France during the years 1761–1765, were well received, and when afterwards published in English, 4 vols., 1770, were highly commended by Johnson. While in Italy on his travels Baretti set on foot a journal of literary criticism, to which he gave the title of *Frusta Letteraria*, the literary scourge. It was published under considerable difficulties and was soon discontinued. The criticisms on contemporary writers were sometimes just, but are frequently disfigured by undue vehemence and coarseness. Among his other numerous works may be mentioned a useful *Dictionary and Grammar of the Italian Language*, and a dissertation on Shakespeare and Voltaire.

BARFLEUR, called formerly Barbeflot, and in the Latin chroniclers *Barbatus Fluctus*, an ancient town of Normandy, in France, now in the department of Manche, 15 miles E. of Cherbourg. It was at one time the seat of an active trade across the Channel, but was ruined and had its harbour filled up by the English in 1346. Cape Barfleur has a lighthouse 271 feet above the sea, in long. 1° 16′ W., lat. 49° 40′ N.

BARHAM, RICHARD HARRIS, a celebrated humourist, better known by his *nom de plume* of THOMAS INGOLDSBY, was born at Canterbury, December 6, 1788. At seven years of age he lost his father, who left him a small estate, part of which was the manor of Tappington, so frequently mentioned in the *Legends*. At nine he was sent to St Paul's school, but his studies were interrupted by an accident which shattered his arm and partially crippled it for life. Thus deprived of the power of bodily activity, he became a great reader and diligent student. In 1807 he entered Brasenose College, Oxford, intending at first to study for the profession of the law. Circumstances, however, induced him to change his mind and to enter the church. The choice seems surprising, for he had from childhood displayed that propensity to fun in the form of parody and punning which afterwards made him a reputation. In 1813 he was ordained and took a country curacy; he married in the following year, and in 1821 removed to London on obtaining the appointment of minor canon of St Paul's Cathedral. Three years later he became one of the priests in ordinary of his Majesty's chapel royal. In 1826 he first contributed to *Blackwood's Magazine*; and on the establishment of *Bentley's Miscellany* in 1837 he began to furnish the series of grotesque metrical tales known as *The Ingoldsby Legends*. These became very popular, were published in a collected form, and have since passed through numerous editions. In variety and whimsicality of rhymes these verses have hardly a rival since the days of *Hudibras*. But beneath this obvious popular quality there lies a store of solid antiquarian learning, the fruit of patient enthusiastic research by the light of the midnight lamp, in out-of-the-way old books, which few readers who laugh over his pages detect. If it were of any avail we might regret that a more active faculty of veneration did not keep him from writing some objectionable passages of the *Legends*. His life was grave, dignified, and highly honoured. His sound judgment and his kind heart made him the trusted counsellor, the valued friend, and the frequent peacemaker; and he was intolerant of all that was mean, and base, and false. In politics he was a Tory of the old school; yet he was the life-long friend of the liberal Sydney Smith, whom in many respects he singularly resembled. Theodore Hook was one of his most intimate friends. Mr Barham was a contributor to the *Edinburgh Review* and the *Literary Gazette*; published a novel in 3 vols., entitled *My Cousin Nicholas*; and, strange to tell, wrote nearly a third of the articles in Gorton's *Biographical Dictionary*. His life was not without such changes and sorrows as make men grave. He had nine children, and six of them died in his lifetime. But he retained vigour and freshness of heart and mind to the last, and his latest verses show no signs of decay. He died in London after a long, painful illness, June 17, 1845, leaving his beloved wife, two daughters, and a son, surviving him. A short memoir, by his son, was prefixed to a new edition of *Ingoldsby* in 1847, and a fuller *Life and Letters* was published in 2 vols. in 1870.

BARI, TERRA DI, a province of Italy, in the district of Apulia, bounded on the N. by the Adriatic, E. and S.E. by the province of Otranto, S.W. by Basilicata, and W. by Capitanata. It has an area of 1782 geographical square miles, and is divided into the three districts of Bari, Barletta, and Altamura. Except in the S. and S.W., where branches of the Apennines occur, the surface is generally level. The soil is for the most part calcareous, with a rich covering of loam. The climate is oppressively hot in summer, but very pleasant during the rest of the year. The only considerable river is the Ofanto, or *Aufidus*; but, in spite of the lack of irrigation, the province is among the best cultivated in the kingdom, producing abundance of grain, flax, tobacco, cotton, wine, oil, almonds, liquorice, &c. Swine, asses, goats, and sheep with a very fine wool, are numerous; and the salt and nitre works form important branches of industry. Among the more important towns besides the capital are Barletta, Trani, Bisceglie, Molfetta, Monopoli, and Fasano on the coast, and Andria Ruvo, Nola, Bitonto, and Conversano somewhat inland.

[1] Summed up thus:—"Our opinion then is this, that Barere approached nearer than any person mentioned in history or fiction, whether man or devil, to the idea of consummate and universal depravity. In him the qualities which are the proper objects of hatred, and the qualities which are the proper objects of contempt, preserve an exquisite and absolute harmony. In almost every particular sort of wickedness he has had rivals. His sensuality was immoderate; but this was a failing common to him with many great and amiable men. There have been many men as cowardly as he, some as cruel, a few as mean, a few as impudent. There may also have been as great liars, though we never met with them or read of them. But when we put everything together, sensuality, poltroonery, baseness, effrontery, mendacity, barbarity, the result is something which in a novel we should condemn as caricature, and to which, we venture to say, no parallel can be found in history."

The population, which is densest along the coast, was 604,540 in 1871.

Bari, the ancient *Barium*, capital of the above province and seat of an archbishop, is situated on a tongue of land projecting into the Adriatic, in lat. 41° 7′ N., and long. 16° 53′ E. It is defended by various fortifications, among which the most important is the citadel, which is about a mile in circumference, and dates from the Norman possession. The general character of the older part of the town is gloomy and irregular, but the newer portion has spacious streets with handsome buildings. The priory of St Nicolo, built by Robert Guiscard in 1087 to hold the relics of the saint, which had been brought from Myra in Lycia, is interesting for its beautiful crypt and the tombs of Robert of Bari and Bona Sforza of Poland. The festival of St Nicholas, on the 8th of May, is still attended by thousands; and his body is believed by the superstitious to supply the *Manna di Bari*. The cathedral of St Sabino, a fine Gothic structure, was barbarously bestuccoed and transformed by Archbishop Gaeta in 1745. Among the other buildings of importance are the palace of the "Intendente," the theatre (a large modern erection), the Lyceum, a college for the education of the nobility, and an "Athenæum." The commercial importance of Bari has been for some time on the increase; and its harbour, augmented by the building of two moles in 1855, has more recently received a still greater extension, while excellent anchorage is also afforded by its roads. The inhabitants are skilful seamen, and carry on a large traffic in their own ships with different parts of the Adriatic. The exports, which consist chiefly of olive oil, wine, mustard seed, cream of tartar, grain, and almonds and other fruits, were valued in 1872 at £642,818, while the imports of the same year amounted to £249,081. The railway to Brindisi was opened in 1865, and another line has since been extended to Taranto. *Barium*, according to the evidence of its coins, was a place of importance in the 3rd century B.C., and had a decided Greek element in its culture; but it never acquired any great influence in the old Roman world, and all allusions to it in the classical authors are of an incidental description. After the fall of the Western empire it was subject in turn to the Greek emperors, to the dukes of Benevento, and to the Saracen invaders. From the last it was delivered in 971 by Louis II., and again in 1002 by the Venetians, who left their Lion of St Mark as an emblem to the city. Not long after it was raised to the rank of capital of Apulia by the Greek emperors, who were soon (1040) compelled to acknowledge it as a free principality under Argyrus. After a four years' siege it was taken in 1070 by the Normans, who lost it in 1137 to Lothaire, but recovered it a few years later. In 1156 it was razed by William the Bad, and has several times suffered a similar fate. In the 14th century Bari became a duchy, which continued to exist till 1558, when it was bequeathed by Bona Sforza to Philip II. of Spain.

See Beatillo, *Historia de Bari*, Napoli, 1637; Lombardi, *Compendio cronologico delle vite degli arcivescovi Baresi*, Napoli, 1697.

BARKING, a town of England, county of Essex, 7 miles E.N.E. of London, on the River Roding, not far from the Thames. It was celebrated for its nunnery, one of the oldest and richest in England, founded about 670 by Erkenwald, bishop of London, and restored in 970 by King Edgar, about a hundred years after its destruction by the Danes. The abbess was a baroness *ex officio*, and the revenue at the dissolution of the monasteries was £1084. The church of St Margaret is an ancient edifice of considerable beauty, with some curious monuments; and the ancient market-house, no longer used, and an embattled gateway, are also worthy of mention. The various dissenting denominations have places of worship in the town. Population in 1871, 5766, principally engaged in the river traffic and in the cultivation of vegetables for the London market. There is no longer much attention paid to the fishery, but various industries have been introduced.

BARLAAM AND JOSAPHAT, Saints. These two saints appear in both the Greek and the Roman Martyrology, in the former under 26th August, in the latter under 27th November. Their story is in the highest degree worthy of note, because it is, in fact, a Christianized version of the Indian legendary history of the Buddha, Sakya Muni.

The remarkable parallel between Buddhistic ritual, costume, and discipline, and those which especially claim the title of Catholic in the Christian church, has often been recognized, even by the most faithful sons of Rome;[1] and though the parallel has perhaps never been elaborated as it might be, some of its more salient points are familiar. Still, many readers may be unaware that Sakya Muni himself, or, as he was by birth, Siddharta, the son of Suddodhana, prince of Kapilavastu (in the north of modern Oudh), has found his way into the Roman calendar as a saint of the church.

The Christian story first appears in Greek among the works of St John of Damascus, an eminent divine, and an opponent of the Emperor Leo the Isaurian in the Iconoclastic movement, who flourished in the early part of the 8th century, and who, before he adopted the monastic life and devoted himself to theology, had held high office at the court of the caliph Abu Jáfar Almansúr, as his father Sergius is said to have done before him.[2]

The outline of the Greek story is as follows:—St Thomas had converted the people of India, and after the eremitic life originated in Egypt, many Indians adopted it. But a powerful pagan king arose who hated and persecuted the Christians, especially the ascetics. After this king, Abenner by name, had long been childless, a boy greatly desired, and matchless in beauty, was born to him, and received the name of Josaphat. The king, in his joy, summons astrologers to predict the child's destiny. They foretell glory and prosperity beyond those of all his predecessors. One sage, most learned of all, assents, but intimates that the scene of this glory will be, not the paternal kingdom, but another infinitely more exalted, and that the child will adopt the faith which his father persecutes. The boy shows a thoughtful and devout turn. King Abenner, troubled by this and by the remembrance of the prediction, selects a secluded city, in which he causes a splendid palace to be built, where his son should abide, attended only by tutors and servants in the flower of youth and health. No stranger was to have access, and the boy was to be cognizant of none of the sorrows of humanity, such as poverty, disease, old age, or death, but only of what was pleasant, so that he should have no inducement to think of the future life; nor was he ever to hear a word of Christ and his religion. Prince Josaphat grows up in this seclusion, acquires all kinds of knowledge, and exhibits singular endowments. At length, on his urgent prayer, the king reluctantly permits him to pass the limits of the palace, after having taken all precautions to keep painful objects out of sight. But through some neglect of orders, the prince one day encounters a leper and a blind man, and asks of his attendants with pain and astonishment what such a spectacle should mean. These, they tell him, are ills to which man is liable. Shall all men have such ills? he asks. And in the end he returns home in deep depression. Another day he falls in with a decrepit old man, and stricken with dismay at the sight, renews his questions, and hears for the first time of death. And in how many years, continues the prince, does this fate befall man? and must he expect death as inevitable? Is there *no* way of escape? No means of eschewing this wretched state of decay? The attendants reply as may be imagined; and Josaphat goes home more pensive than ever, dwelling on the certainty of death, and on what shall be thereafter.

At this time Barlaam, an eremite of great sanctity and knowledge, dwelling in the wilderness of Sennaritis, divinely warned,

[1] It has been alleged that Père Huc, on returning to Europe, was astonished to find his celebrated journey to Lhasa in the *Index*, on the ground of such recognition. But this seems to be untrue.

[2] St John's authorship of the story has been disputed. Prof. Max Müller, in the paper quoted below, seems to dispose sufficiently of the objections. None of the old editions of St John's works contain the *Greek* of the story. This, Prof. Muller states, was first published in 1832 by Boissonade, in his *Analecta Græca*, vol. iv.

travels to India in the disguise of a merchant, and gains access to Prince Josaphat, to whom he imparts the Christian doctrine and commends the monastic life. Suspicion arises and Barlaam departs. But all attempts to shake the prince's convictions fail. As a last resource the king sends for Theudas, a magician, who removes the prince's attendants and substitutes seductive girls; but all their blandishments are resisted through prayer. The king abandons these efforts and associates his son in the government. The prince uses his power to promote religion, and everything prospers in his hands. At last Abenner himself yields to the faith and after some years of penitence dies. Josaphat surrenders the kingdom to a friend called Barachias, and departs for the wilderness. After two years of painful search, and much buffeting by demons, he finds Barlaam. The latter dies, and Josaphat survives as a hermit many years. King Barachias afterwards arrives, and transfers the bodies of the two saints to India, where they are the source of many miracles.

Now this story is, in all essentials and in many details, *mutatis mutandis*, the story of Buddha. For particulars we must refer to the papers of M. Müller and F. Liebrecht cited below; we can indicate but one example in the prominent episode of Sakya's youth, his education in a secluded palace, his encounter successively with a decrepit old man, with a man in mortal disease and poverty, with a dead body, and, lastly, with a religious recluse radiant with peace and dignity, and his consequent abandonment of his princely state for the ascetic life in the jungle. Some of the correspondences in the two stories are most minute, and Prof. Muller has pointed out that even the phraseology, in which some of the details of Josaphat's history are described, almost literally renders the Sanskrit of the *Lalita Vistara*.

We have given but the skeleton of the history of Barlaam and Josaphat. It is filled out with episodes and apologues, several of which also have been traced to Buddhist sources. These stories no doubt promoted the vast mediæval popularity of the legend in both the Greek and the Latin Churches. Its first favour in the former seems to have been due to its embodiment in the *Lives of the Saints*, as compiled anew by Simeon the Metaphrast, a person of disputed age, but not of later date than 1150 A.D. Selections from his work, in which this legend takes the lead, continue to be issued in Romaic as works of popular edification.

At what time the two saints first found their place in the Roman martyrology we have not been able to ascertain, but their story figures at length in the *Speculum Historiale* of Vincent of Beauvais, and more briefly in the *Golden Legend* of Jacobus de Voragine, both of the 13th century. There is a church bearing the dedication *Divo Iosaphat* in Palermo, and probably others in other Catholic cities.

The story continued for centuries to be one of the most popular works in Christendom. It was translated into most European tongues, including Bohemian, Polish, and Icelandic. A version in the last, executed by a Norwegian king, dates from 1204; in the East there were versions in (at least) Arabic, Ethiopic, Armenian, and Hebrew; whilst a translation into the Tagala language of the Philippines was printed at Manilla in 1712. The story was rendered into poems and miracle plays. Moreover, its episodes and apologues have furnished material to poets and story-writers of very diverse ages and characters, *e.g.*, to Boccaccio, to Gower, to the compiler of the *Gesta Romanorum*, to Shakespeare himself, and to the late W. Adams, author of the *King's Messengers*.

The identity of the stories of Buddha and St Josaphat was recognized by the historian of Portuguese India, Diogo de Couto, as may be seen in his history (Dec. v. liv. vi. cap. 2). In modern times it was first noticed (according to Prof. M. Müller) by M. Laboulaye, in the *Journal des Débats* (21 26 July, 1859); but it was more elaborately set forth by the learned Dr Felix Liebrecht a year later (*Jahrbuch fur Roman. und Engl. Litteratur*, ii. p. 314); and was treated with his usual grace by Prof. Muller himself in his lecture on the "Migration of Fables" (see *Contemp. Review* for July 1870, pp. 588 *sqq.*) (H. Y.)

BARLETTA, the ancient *Bardulum*, called in the Middle Ages *Barolum*, a fortified seaport town of Italy, the seat of an archbishop, in the province of Terra di Bari. It is 33 miles N.W. of Bari, in lat. 41° 19′ 26″ N., long. 16° 18′ 10″ E. The town is well built and handsome; the houses are large, and the streets wide and well paved. It has a fine Gothic cathedral (S. Maria Maggiore) with a lofty spire, a number of churches and convents, an orphan asylum, a college, a theatre, and a colossal statue, supposed by some to be of the Emperor Heraclius, but this is denied by other art critics. The harbour is formed by a mole, on which a lighthouse is erected, and it is commanded by the citadel. It is only capable of admitting small vessels, but the town has a considerable trade in grain, wine, oil, fruit, salt, &c. Barletta was once one of the strongest cities in Italy, and in the 13th and 14th centuries was a favourite residence of the kings of Naples. It was here that the first tournament in that part of Italy was held in 1259, and in 1503 a remarkable combat took place in the neighbourhood between two chosen bands of Italian and French knights, led by Colonna and Bayard respectively. Population, 28,613. (See Marullo, *Diss. stor. sopra il colosso di Barletta*, Naples, 1816.)

BARLEY (*Hordeum*), a most important genus of the cereal plants which belongs peculiarly to temperate regions. Four distinct species of barley, cultivated for the production of grain, are commonly enumerated,—1st, common or two-rowed barley, *Hordeum distichum*; 2d, Bere or Bigg, *H. vulgare*; 3d, six-rowed barley, *H. hextastichum*; and 4th, fan, spratt, or battledore barley, *H. zeocriton*. Of these species, but chiefly of the first two, very many varieties are recognized by cultivators, and new kinds are constantly being introduced. Barley is the most hardy of all cereal grains, its limit of cultivation extending further north than any other; and, at the same time, it can be profitably cultivated in sub-tropical countries. The opinion of Pliny, that it is the most ancient aliment of mankind, appears to be well founded, for no less than three varieties have been found in the lake dwellings of Switzerland, in deposits belonging to the Stone Period. According to Professor Heer these varieties are the common two-rowed (*H. distichum*), the large six-rowed (*H. hextastichum densum*), and the small six-rowed (*H. hextastichum sanctum*). The last variety is both the most ancient and the most commonly found, and is the sacred barley of antiquity, ears of which are frequently represented plaited in the hair of the goddess Ceres, besides being figured on ancient coins. The cultivation of barley in ancient Egypt is indicated in Exod. ix. 31. Till within recent times barley formed an important source of food in northern countries, and barley cakes are still to some extent eaten. Owing, however, to its poverty in that form of nitrogenous compound called gluten, so abundant in wheat, barley-flour cannot be baked into vesiculated bread; still it is a highly nutritious substance, the salts it contains having a high proportion of phosphoric acid, and on it the Greeks trained their athletes. The following is the composition of barley-meal according to Von Bibra, omitting the salts:—

Water	15	per cent.
Nitrogenous compounds	12·981	,,
Gum	6·744	,,
Sugar	3·200	,,
Starch	59·950	,,
Fat	2·170	,,

Barley is now chiefly cultivated for malting, to prepare spirits and beer (see BREWING), but it is also largely employed in domestic cookery. For the latter purpose the hard, somewhat flinty grains are preferable, and they are prepared by grinding off the outer cuticle which forms "pot barley." When the attrition is carried farther, so that the grain is reduced to small round pellets, it is termed "pearl barley." Patent barley is either pot or pearl barley reduced to flour. Under the name *decoctum hordei*, a pre-

paration of barley is included in the British Pharmacopœia, which is of value as a demulcent and emollient drink in febrile and inflammatory disorders. For the cultivation of barley, see AGRICULTURE, vol. i. p. 358.

The following table shows the quantities and values of barley imported into the United Kingdom in 1873:—

	Cwts.	£
From Russia	1,119,094	408,344
„ Sweden	182,004	86,366
„ Denmark	850,011	425,856
„ Germany	1,138,737	572,640
„ France	1,970,958	966,740
„ Turkey	2,905,646	1,137,147

Total	9,241,063	4,013,572

BARLOW, JOEL, an American poet and politician, born in 1755 at Reading in Connecticut. In 1774, some years after his father's death, he was entered at Yale College, New Haven, where he soon began to manifest considerable taste for poetry and power of composition. A few small pieces published by him were received with some degree of public favour. During his vacations he had taken part with the colonists in several engagements against the British, and immediately after completing his course, he qualified himself for the church, and was appointed chaplain to a regiment. This post he held till the conclusion of peace between Britain and America, when he settled in the village of Hartford, and began to practise as a lawyer. He also conducted a newspaper, and about the same time published his best poem, the *Vision of Columbus*, a vigorous and spirited piece of writing. About the year 1788 he gave up his newspaper and his legal practice, and came to Europe as the agent for a land company. Having discovered that this company was merely a swindling concern, he severed his connection with it, but did not return to America. In London he became acquainted with some of the most advanced liberal thinkers, and published several political tracts of a decidedly revolutionary character. In 1793, after having been some time in France, he accompanied the Commission of the National Convention, which was sent to organize the newly-acquired territory in Savoy. During his residence in Paris he engaged in commercial transactions, by which he acquired considerable fortune and importance. In 1795 he was appointed American consul at Algiers, and efficiently discharged the duties of that office. In 1805 he returned to America and began to interest himself in the politics of his own country. A pamphlet of his, sketching a plan of national education, was received with great favour. In 1808 he published an enlarged edition of his great poem, under the title *Columbiad*. It was magnificently illustrated, but did not achieve the popularity of its predecessor. In 1811 he was appointed minister plenipotentiary to France, with the object mainly of negotiating a commercial treaty and of obtaining compensation for some American property that had been unjustly confiscated. To accomplish this he required a personal interview with Napoleon, and set out to meet the emperor, who was at Wilna. On his way he was attacked with inflammation of the lungs, and died at a Polish village near Cracow, on the 22d December 1812.

BARLOW, PETER, an able writer on pure and applied mathematics, was born at Norwich in 1776, and died in 1862. He received a very ordinary education, but improved himself by his own exertions. In 1806 he was appointed mathematical master in the Woolwich Academy, and filled that post for forty one years. In 1823 he was made a Fellow of the Royal Society, and two years later received the Copley medal. He received many distinctions from British and foreign scientific societies. Mr Barlow's principal works are—*Elementary Investigation of the Theory of Numbers*, 1811; *New Mathematical and Philosophical Dictionary*, 1814; *Essay on Magnetic Attractions*, 1820. The investigations on magnetism led to the important practical discovery of a means of rectifying or compensating compass errors in ships. Besides compiling numerous useful tables, Mr Barlow contributed largely to the *Encyclopædia Metropolitana*. The most important of his articles are—"Theory of Numbers," "Mechanics," "Hydrodynamics," "Pneumatics," "Optics," "Astronomy," "Magnetism," and "Electro-Magnetism," along with the huge volume on "Manufactures."

BARMECIDES, or descendants of Barmak, were a noble Persian family, who attained great power under the Abbaside caliphs. Barmak, the first of them, was a Ghebre, or Persian fire-worshipper, and is supposed to have been a native of the district of Khorassan. He was introduced to the caliph Abd-ul-Malik, and acquired great power under him. His family prospered, and his grandson, Yahya, was vizier to the caliph El-Mahdy, and tutor of the famous prince Haroun-al-Raschid, celebrated in the *Thousand and One Nights*. Yahya's sons occupied high offices, one of them, Ja'afar (the Giafar of the *Arabian Nights*), being vizier and constant companion of Haroun. The caliph, however, conceived suspicions against the Barmecides, and in 802 beheaded Ja'afar with great cruelty, condemned the whole family to prison, and confiscated their property. Oriental historians give a romantic and not improbable reason for the caliph's conduct towards his vizier. Ja'afar had been married to Haroun's favourite sister, Abbasah, on condition that he should never see his wife save in presence of the caliph. He neglected this injunction, and Abbasah bore a son, who was brought up secretly. The caliph became aware of this, and in his wrath punished Ja'afar and all his family. The use of the expression *Barmecides' Feast*, to denote an imaginary banquet, is drawn from one of the tales in the *Arabian Nights*, where an entertainment of merely imaginary viands is served up to a hungry man by one of the Barmecides.

BARMEN, a town of Rhenish Prussia, in the government of Dusseldorf and circle of Elberfeld, on the Bergisch-Markisch railway. It is formed by the combination of a large number of separate villages, which stretch along the northern valley of the Wupper for a distance of six miles in almost perfect continuity with Elberfeld. The first of these to obtain a separate civic organization was Gemarke, which may thus be regarded as the nucleus of the whole. The rapid development of manufacturing activity, to which the town owes its origin, only dates from the beginning of the 18th century. It is the chief seat of ribbon-weaving in Germany, and manufactures thread, lace, buttons, braids, cotton, cloth, silk stuffs, steel wares, and plated goods. There are also numerous bleachfields, printfields, dyeworks,—famous for their Turkey-red,—soap-works, chemical-works, and potteries. A chamber of commerce and a commercial tribunal hold their sessions in the town, which also possesses an exchange, a music hall, a deaf and dumb asylum, numerous schools, and a variety of churches. The most of the inhabitants are Protestants of various sects. The Rhenish-Westphalian Missionary Society maintains a theological seminary in the town and possesses an ethnographical museum. Population, 74,449.

BARNABAS (בַּר־נְבוּאָה) was the surname given by the apostles to Joses, "a Levite, of the country of Cyprus," who, though like Paul not of the twelve, was with him recognized among the number of the apostles. The name (υἱὸς παρακλήσεως), translated "son of consolation" in the authorized version (Acts iv. 36) would be better rendered

"son of exhortation" or "of prophecy." Barnabas is first mentioned in the Acts (iv. 36, 37) as having sold his land and laid the money at the apostles' feet. He next appears as introducing Paul after his conversion to the other apostles (Acts ix. 27), from which a previous acquaintance has been inferred. Subsequent notices record a year's residence along with Saul at Antioch, where they "taught much people" (xi. 22–26), a visit to Jerusalem with contributions for the poorer brethren there (xi. 27–30), the ordination of Saul and Barnabas for the work to which they were called by the Holy Ghost (xiii. 2, 3), and a missionary journey of the two apostles to Cyprus and various cities of Asia Minor (xiii. xiv.) When the dissension arose as to the necessity of circumcision, Paul and Barnabas were sent to Jerusalem by the church at Antioch to consult the "apostles and elders" on the question (xv. 1–4). Soon after their return to Antioch they resolved to undertake a second missionary journey; but a difference arose between them in regard to the determination of Barnabas to take his sister's son, John Mark, along with him. "The contention was so sharp between them" (xv. 39) that they separated, Barnabas and Mark going to Cyprus, while Paul and Silas went to Syria and Cilicia. No further account of the career of Barnabas is given in the New Testament, with the exception of one or two incidental allusions in St Paul's epistles (1 Cor. ix. 6; Gal. ii. 1, 9, 13). Later writings and additions have attempted to supply what is wanting in the Scriptural narrative, but they contain no facts that can be accepted as historically certain. According to Clement of Alexandria, Barnabas was one of the seventy disciples. Various accounts of still later date allege that he studied under Gamaliel along with Saul, that he suffered martyrdom at Cyprus, and that his body was discovered in the reign of the Emperor Zeno. He is also said to have been the founder and first bishop of the church at Milan. The festival of St Barnabas is held on the 11th of June.

BARNABAS, EPISTLE OF, and GOSPEL OF. See APOSTOLIC FATHERS and GOSPELS.

BARNARD CASTLE, a market and manufacturing town and parish in the county of Durham, on the banks of the Tees, 246 miles from London. It consists of one main street, about a mile long, with a number of smaller ones branching off on each side. The principal building in the high street is the town-hall, an octagonal structure dating from 1747. St Mary's church, built in the 12th century, and restored in 1871, contains some curious monuments; but the building of chief interest is the castle, from which the town derives its name, and which is the principal scene of Scott's *Rokeby*. This was founded in 1132 by Barnard Baliol, an ancestor of the competitor with Bruce for the Scottish crown, and was reduced to a ruinous condition by the siege of 1569, when it was defended for Queen Elizabeth by Sir George Bowes of Streatlam. The remains still extend over a space of more than six acres. A remarkable building, known as the Bowes' Mansion and Museum, was in 1874 bequeathed to the town by a descendant of the gallant knight. It contains a valuable collection of works of art, and is one of the finest edifices of the kind in the kingdom. The principal manufactures of Barnard Castle are carpets, woollen cloth, and shoe-thread. The corn-market is one of the largest in the north of England. A line joining the North-Eastern and the London and North-Western Railways passes immediately to the north of the town. In the neighbourhood are Rokeby, Egglestone Abbey, Raby Castle, and Lartington Hall. (See Sir Walter Scott's *Rokeby*, and Atkinson's *Handbook of Barnard Castle*, 1874.)

BARNAUL, a town of Asiatic Russia, in the government of Tomsk, and capital of a circle to which it gives its name. It is situated in a wide plain which is bounded by off-shoots of the Altai Mountains, and is built on both sides of the Barnaulka River at its confluence with the Ob, in lat. 53° 20′ N., and long. 83° 26′ E. It is the capital of an extensive mining district, and the seat of a board of administration. Besides its numerous smelting-furnaces, it possesses glassworks, a bell-foundry, and a mint; and it has also a library, an observatory, established in 1841, a mining school, a museum with a rich collection of mineral and zoological specimens, and a theatre, in addition to the governor's residence, the barracks, and other buildings belonging to its civic organization. Barnaul was founded in 1730 by Akynthies Demidoff (to whose memory a monument has been erected), was raised to the rank of a town in 1771, and became capital of the circle in 1822. Population, 12,927.

BARNAVE, ANTOINE PIERRE JOSEPH MARIE, one of the greatest orators and noblest actors and victims of the first French Revolution, was born at Grenoble in Dauphiny, October 22, 1761. He was of a Protestant family. His father was an advocate to the parliament of Grenoble, and his mother was a woman of high birth, superior ability, and noble character. He was at once thoughtful and passionate, studious and social, handsome in person and graceful in manners. He was brought up to the law, and at the age of twenty-two made himself favourably known by a discourse pronounced before the local parliament on the division of political powers. Dauphiny was one of the first of the provinces to feel the excitement of the coming revolution; and Barnave was foremost to give voice to the general feeling, in a pamphlet entitled *Esprit des édits enregistrés militairement le 20 Mai 1788*. He was immediately elected deputy, with his father, to the States of Dauphiny, and took a prominent part in their debates. A few months later he was transferred to a grander field of action. The States-general were convoked at Versailles for May 5, 1789, and Barnave was chosen deputy of the *Tiers État* for his native province. He soon made an impression on the Assembly, and became the friend of most of the leaders of the popular party. He took part in the conferences on the claims of the three orders, drew up the first address to the king, and supported the proposal of Sieyès that the Assembly should declare itself National. Though a passionate lover of liberty, he knew that excess is the ruin of liberty, and maintained the necessity for the individual and for the community of both freedom and restraint. He hoped to secure the freedom of France and her monarchy at the same time. But he was almost unawares borne away by the mighty currents of the time, and he took part in the attacks on the monarchy, on the clergy, on church property, and on the provincial parliaments. With the one exception of the mighty Mirabeau, Barnave was the most powerful orator of the Assembly. On several occasions he stood in opposition to Mirabeau. After the fall of the Bastille he wished to save the throne. He advocated the suspensive veto, the system of two chambers, and the establishment of trial by jury in civil causes. His conflict with Mirabeau on the question of assigning to the king the right to make peace or war was one of the most striking scenes in the Assembly. About this time, after a vehement debate, he fought a duel with Cazales, in which the latter was slightly wounded. About the close of October 1790 Barnave was called to the presidency of the Assembly. On the death of Mirabeau a few months later, Barnave paid a high tribute to his worth and public services, designating him the Shakespeare of oratory. On the arrest of the king and the royal family at Varennes, while attempting to escape from France, Barnave was one of the three appointed to conduct them back to Paris. On the journey he was deeply affected by the mournful fate of these

royal persons, and resolved to do what he could to alleviate their sufferings. In one of his most powerful speeches he maintained the inviolability of the king's person. His public career came to an end with the close of the Constituent Assembly, and he returned to Grenoble at the beginning of 1792. His sympathy and relations with the royal family, and his desire to check the downward progress of the Revolution, brought on him the suspicion and persecution of the more violent party. At the end of August 1792 he was arrested and imprisoned, and in November 1793 was transferred to Paris. The nobility of his character was proof against the assaults of suffering. "Better to suffer and to die," he said, "than lose one shade of my moral and political character." On November 28 he appeared before the Revolutionary Tribunal, in company with Duport-Dutertre, and two days later they both perished by the guillotine.

BARNES, Albert, a theologian of America, specially distinguished as a Biblical expositor, was born at Rome in the state of New York, 1st December 1798, and died at Philadelphia 24th December 1870. In 1820 he graduated at Hamilton College, and in the same year commenced his studies for the ministry at Princeton Theological Seminary. Soon after taking licence he was called to the Presbyterian church in Morristown, New Jersey, from which he was transferred to the pastoral charge of the first Presbyterian church of Philadelphia in 1830. In 1867 he was compelled to resign owing to failing health. Barnes held a prominent place in the New School branch of the Presbyterians, to which he had adhered on the division of the denomination. He was an eloquent preacher, but his wide-spread reputation rests chiefly on his expository works, which have probably had a larger circulation both in Europe and America than any others of their class. Of the well-known *Notes on the New Testament* it is said that more than a million volumes had been issued at the time of their author's death. The *Notes* on Job, the Psalms, Isaiah, and Daniel, found scarcely less acceptance. Displaying little original critical power, their chief merit lies in the fact that they bring the results of the criticism of others within the reach of general readers. Barnes was the author of several other works of a practical and devotional kind.

BARNES, Joshua, an English scholar, born in 1654. In 1695 he was chosen queen's professor of Greek, a language which he wrote and spoke with the utmost facility. One of his first publications was a whimsical tract, entitled *Gerania, or a New Discovery of the Little Sort of People called Pygmies*. Among his other works are a *Life of Edward III.*, in which he introduces his hero making long and elaborate speeches; *Sacred Poems;* the *Life of Oliver Cromwell the Tyrant;* some dramatic pieces; a poetical paraphrase on the history of Esther, in Greek verse, with a Latin translation, &c. He also published editions of *Euripides*, *Anacreon*, and Homer's *Iliad* and *Odyssey*, with notes and a Latin translation. He died in 1712.

BARNET, or Chipping Barnet, a market-town in the county of Hertford, 11 miles from London, on the great northern road. Near it, in 1471, was fought the decisive battle between the houses of York and Lancaster, in which the great earl of Warwick fell. The parish church dates from the 15th century, and the free school was founded by Elizabeth in 1573. The market, held on Monday, is large; and there are great cattle fairs. In the neighbourhood is the village of East Barnet, with a very ancient church. Population of parish in 1871, 3375.

BARNEVELDT, Jan van Olden, Grand Pensionary of Holland, who played a great part and rendered the most signal services to his country in the long conflict with Philip II. of Spain, was born in 1547. He was a native of Amersfoort in the province of Utrecht, and could boast of a long line of noble ancestors. Endowed with superior abilities, he was educated for the profession of the law, and commenced practice as an advocate at the Hague in 1569. He sympathized deeply with his countrymen in their resolution to throw off the hated yoke of Spain, and served as a volunteer at the sieges of Haarlem and Leyden. In 1575 he married; and in the following year he was appointed to the honourable post of counsellor and chief-pensionary of Rotterdam. In 1585, when, in consequence of the assassination of the sagacious and resolute leader of the Dutch, and the general success of the Spaniards under the Prince of Parma, the cause of the patriots seemed almost hopeless, Barneveldt was chosen head of an embassy to Queen Elizabeth, to ask for her assistance and to offer her the sovereignty of the United Provinces. The queen agreed to give aid both in money and in men, but refused to accept the sovereignty. An expedition was sent under the command of Dudley, earl of Leicester, on whom the Dutch conferred supreme and absolute authority. Barneveldt was then raised to the high office of advocate-general of Holland and West Friesland. Dissatisfied and indignant at Leicester's incompetence, arrogance, and mismanagement, he endeavoured to limit his powers. For this purpose he succeeded in persuading the States to appoint Maurice of Nassau, the young son of the late Prince of Orange, stadtholder and captain-general of Holland and Zealand, thus contributing to place in the highest position the man who was afterwards to become his great antagonist. Leicester was recalled at the close of 1586. In the course of a few years Barneveldt, by his prudence and energy in administration, succeeded in restoring order and materially improving the financial affairs of the States. He proposed to resign in 1592, but at the urgent entreaty of the States retained his post. In 1598 he was sent on an embassy to Henry IV. of France, the object of which was to strengthen and maintain the friendship of France and the United Provinces. In 1603, on the accession of James I. to the throne, Barneveldt was again sent to England as head of an embassy, and in conjunction with the French ambassador, M. de Rosny, afterwards duke of Sully, negotiated an arrangement for further assistance against the Spaniards. In 1607, having first insisted on and obtained a recognition of the independence of the Provinces, he began negotiations with Spain with a view to establish a truce. He had to contend against the opposition of the stadtholder and the army, and to suffer from unmerited popular suspicions of taking bribes from the Spanish court. But he triumphed over all difficulties, and on April 9, 1609, the famous twelve years' truce was concluded. From this time Maurice was his sworn foe. The two men were leaders of two great political parties, and the struggle between them was embittered by the admixture of theological and ecclesiastical controversy. In the strife then going on between the Gomarites (the Calvinistic party) and the Arminians, Maurice sided with the former, while Barneveldt supported the latter. Maurice was aiming at the sovereign power; Barneveldt resolutely maintained the freedom of the republic. The clerical party, who looked up to Prince Maurice as their chief, were bent on getting the Calvinistic system established as the state religion, and on refusing to tolerate any other system; Barneveldt and the Arminians contended that each province should be free to adopt the form which it preferred. Barneveldt was the consistent champion of the supremacy of the civil authority, and "the prime minister of Protestantism" (Motley). The convocation of a National Synod was proposed by the party of the stadtholder and resisted by Barneveldt. When disturbances broke out against the Arminians, Maurice refused

to suppress them, and disarmed the militia organized for the purpose by Barneveldt. The former now assumed the chief power. An interview took place on August 17, 1618, between the advocate and the stadtholder; each adhered resolutely to his own views, and the meeting remained fruitless. Barneveldt, with his friends Grotius and Hoogerbeets, was arrested and imprisoned on the 29th. In November following, in pursuance of the command of Prince Maurice, the famous Synod of Dort assembled. A few days later the trial of the prisoners began before a special commission. The proceedings were illegal; the accusations against Barneveldt were fully disproved, but he was unjustly found guilty and sentenced to death. This sentence was unscrupulously confirmed by the clerical synod. It was a foregone conclusion, and Barneveldt had seen clearly that there was no hope for him. On the 14th of May 1619, just five days after the closing of the synod, the venerable statesman and patriot, then in his seventy-first year, was beheaded at the Hague. He met his fate without a word of regret, without a sign of fear. His calm courage and his tenderness of heart are attested by a letter, still extant, written to his wife a few hours before his execution. Besides his wife, Maria van Utrecht, Barneveldt left two sons and two daughters. Four years after their father's death the sons took part in a plot against Prince Maurice; one of them made his escape and entered the service of Spain, the other was arrested and beheaded.

An elaborate history of *The Life and Death of John of Barneveld, with a View of the Primary Causes and Movements of the Thirty Years' War*, by J. L. Motley, author of the *Rise of the Dutch Republic*, appeared in 1874.

BARNSLEY, or BLACK BARNSLEY, mentioned in *Domesday Book* as Bernesleye, a town and municipal borough in the West Riding of Yorkshire, 171 miles from London and about 11 north of Sheffield. It is situated on rising ground to the west of the River Dearne, in a district of considerable natural beauty. The manufacture of iron and steel, and the weaving of linen and other cloth, are the two principal industries; but there are also bleachfields, printfields, dyeworks, sawmills, cornmills, and malt-houses; and the manufacture of glass, needles, and wire is still carried on. The last-mentioned industry dates from the reign of James I., and was for a long time the staple of the place There are large coal-fields in the neighbourhood, which, indeed, extend under the town; and these afford employment to considerable numbers. The coal is largely exported to London and Hull, for domestic and other purposes, the coke formed from it also being in great demand. Besides the means of communication afforded by several railway lines, Barnsley has the advantage of two canals, the one known as the Barnsley-and-Wakefield and the other as the Dearne-and-Dove. Among the more important of its public buildings are the church of St Mary's, St George's (built in 1823), St John's (1858), the county court (1861), and the bank (1861). There are a number of educational and benevolent institutions of some importance; the free grammar school dates from 1665, a subscription library was started in 1808, and a philosophical society was founded in 1828. In 1862 a handsome park of about 20 acres was presented to the town by the widow of Joseph Locke, M.P. About a mile from the town are the ruins of Monk Bretton, a Cluniac priory. Population in 1871, 23,021.

BARNSTABLE, a seaport town, and capital of the county of the same name, in the state of Massachusetts, North America. It is situated on the south side of a bay of the same name, which opens into Cape Cod Bay, and is 65 miles S.E. of Boston. The population, which is largely sea-faring, amounted in 1870 to 4793.

BARNSTAPLE, a market and borough town of England, county of Devon, 40 miles N.W. of Exeter. It is situated on the River Taw, 6 miles from its mouth, but has always

Arms of Barnstaple.

been considered a seaport. The stream, which is only navigable for small craft, is here crossed by an ancient stone bridge of 16 arches, and by a railway bridge on the Ilfracombe line. The town is handsome and well built; it was incorporated in the reign of Henry I., and has returned two members to parliament since the time of Edward I. The woollen trade, for which it was once famous, has now entirely declined; but it manufactures lace, sail-cloth, and fishing-nets, and has extensive potteries, tanneries, sawmills, and foundries, while shipbuilding is also successfully carried on. The public buildings and institutions include a large church, a guildhall (1826), a music hall, a free grammar school, a literary institute, national and charity schools, an infirmary (1832), and a dispensary, and the finest market-place in the West of England. The poet Gay was born in the vicinity, and received his education at the grammar school here, which at an earlier period had numbered Bishop Jewel among its *alumni*. Population in 1871, 11,659. Barnstaple is a town of considerable antiquity, and was erected, it is said, by Athelstan into a borough. At the time of the Norman Conquest it numbered between forty and fifty burgesses. Joel of Totness, to whom it was transferred, built a castle and founded a priory of Cluniac monks. In 1588 the town was able to furnish three vessels against the Spanish Armada.

BAROCCHIO, or BAROZZI, GIACOMO DA VIGNOLA, architect, born at Vignola in the Modenese territory, in 1507. He succeeded Michel Angelo as the architect of St Peter's, and executed various portions of that fabric, besides a variety of works in Rome and other parts of Italy. The designs for the Escorial were also supplied by him. He is the author of an excellent work on the *Five Orders of Architecture*. His character as a man was worthy of his genius; for to his extensive acquirements and exquisite taste were superadded an amenity of manners and disposition and a noble generosity, that won the affection and admiration of all who knew him. He died in 1573, at the age of sixty-six.

BAROCCI, or BAROCCIO, FEDERIGO, painter, was born in 1528 at Urbino, where the genius of Raphael inspired him. In his early youth he travelled to Rome, where he painted in fresco, and was warmly commended by Michel Angelo. He then returned to Urbino, where, with the exception of some short visits to Rome, he continued to reside till his death in 1612. He acquired great fame by his paintings of religious subjects, in the style of which he to some extent imitated Correggio. His own followers were very numerous, but according to Lanzi, carried their master's peculiarities to excess. Barocci also etched from his own designs a few prints, which are highly finished, and executed with great softness and delicacy. (See Lanzi, *Hist. of Painting*, i. 440.)

BARODÁ, a city of British India, the capital of the native state known as the Gaikwár's dominions, is situated near the River Biswamintri, in 22° 16′ N. lat., and 73° 14′ E. long. The Government of Bombay exercises a political

superintendence over the Gaikwár, and a British political agent resides at Barodá. The town is fortified, but has no great strength. Thornton states the population at 140,000. Barodá contains the chief court of the state, the Gaikwár himself presiding in appeals from the decisions of the other courts in his territory. The town contains only one higher class school, the High School,—attended in 1872 by 658 pupils, of whom 155 were learning English, 221 Marháthí, and 282 Gujráthi. There are also two vernacular schools in the town. The late Gaikwár, Malhár Ráo, was installed in 1871. The princes of Barodá date their importance from the Marhattá confederacy, which in the last century spread devastation and terror over India. Shortly after 1721 the ruling chief, one Pelájí, carved a fertile slice of territory out of Gujárát. Another enjoyed the title of "Leader of the Royal Troops" under the Peshwá. During the last thirty-two years of the century the house fell a prey to one of those bitter and unappeasable family feuds which are the ruin of great Indian families. In 1800 the inheritance descended to a prince feeble in body and almost idiotic in mind. British troops were sent in defence of the hereditary ruler against all claimants; a treaty was signed in 1802, by which his independence of the Peshwá, and his dependence on our own Government, were secured. Three years later these and various other engagements were consolidated into a systematic plan for the administration of the Barodá territory, under a prince with a revenue of three-quarters of a million sterling, perfectly independent in all internal matters, but practically kept on his throne by subsidiary British troops. Since then the history of the Gaikwárs has been very much the same as that of most territorial houses in India: an occasional able minister, more rarely an able prince; but, on the other hand, a long dreary list of incompetent heads, venal advisers, and taskmasters oppressive to the people. Of late years they have been more than usually unfortunate. Family feuds raged fiercer than ever, and the late Gaikwár was long imprisoned by his brother, the former ruler, on a charge of attempted fratricide. The miserable scandals of the Barodá Ráj need not be revived here. Suffice it to say, that Malhár Ráo found himself suddenly brought from prison and placed upon the throne, and that his conduct as ruler was what might have been expected in such a case. Frequent complaints of his mismanagement and oppression were brought before the British Government, and in 1873 a commission of English officers was appointed to inquire into the affairs of the state, and its management by the Gaikwár. Since then misrule has advanced with a rapid foot. After one or two feints at reforming his government, the Gaikwár returned to his old courses. An attempt in 1874 to poison the British Resident at his court brought affairs to a crisis, and early in 1875 the Gaikwár was tried by a mixed commission of eminent British officers and natives of rank. A unanimous verdict was not obtained touching the particular attempt at poisoning; but Lord Northbrook, as Viceroy of India, found it necessary to depose the Gaikwár, and to appoint another member of the Barodá family to rule in his stead.

BAROMETER, the instrument by which the weight or pressure of the atmosphere is estimated. The barometer was invented by Torricelli, a pupil of Galileo, in 1643. It had shortly before been found, in attempting to raise water from a very deep well near Florence, that, in spite of all the pains taken in fitting the piston and valves, the water could by no effort be made to rise higher in the pump than about 32 feet. This remarkable phenomenon Torricelli accounted for by attributing pressure to the air. He reasoned that water will rise in a vacuum only to a certain height, so that the downward pressure or weight of the column of water will just balance the pressure of the atmosphere; and he further argued that if a fluid heavier than water be used it will not rise so high in the tube as the water. To prove this, he selected a glass tube about a quarter of an inch in diameter and 4 feet long, and hermetically sealed one of its ends; he then filled it with mercury and, applying his finger to the open end, inverted it in a basin containing mercury. The mercury instantly sank to nearly 30 inches above the surface of the mercury in the basin, leaving in the top of the tube an apparent vacuum, which is, indeed, one of the most perfect that can yet be produced, and is called after this great experimenter, the *Torricellian vacuum.* He next converted the mercurial column into a form suited for observation by bending the lower end of the tube, thus constructing what has since been called the siphon barometer. The fundamental principle of the barometer cannot be better illustrated than by his experiment (see fig. 2). In truth, a scale is all that is required to render this simple apparatus a perfect barometer.

The heights of the columns of two fluids in equilibrium are inversely as their specific gravities; and as mercury is 10,784 times heavier than air, the height of the atmosphere would be 10,784 times 30 inches, or nearly five miles, if it were composed of layers equally dense throughout. But since air becomes less dense as we ascend, owing to its great elasticity and the diminished pressure, the real height of the atmosphere is very much greater. From observations of luminous meteors, it has been inferred that the height is at least 120 miles, and that, in an extremely attenuated form, it may even considerably exceed 200 miles.

Various fluids might be used in constructing barometers. **Fluids**
If water were used, the barometric column would be about 35 **used.**
feet long. The advantages, however, which *water barometers* might be supposed to possess in showing changes of atmospheric pressure on a large scale, are more than counterbalanced by a serious objection. The space in the tube above the column of water is far from being a vacuum, being filled with aqueous vapour, which presses on the column with a force varying with the temperature. At a temperature of 32° Fahr. the column would be depressed half an inch, and at 75° a foot. Since in mercurial barometers the space at the top of the column is one of the most perfect vacuums that can be produced, the best fluid for the construction of barometers is mercury. It is therefore the only fluid used where scientific accuracy is aimed at. Pure mercury must be used in filling the tubes of barometers; because if it be impure, the density will not be that of mercury, and, consequently, the length of the columns will not be the same as that of a column composed of pure mercury alone. Even should the density happen to be the same as that of pure mercury the impurities would soon appear, impeding the action of the fluid as it rises and falls, and thus rendering the instrument unfit for accurate observation. In filling barometer tubes, air and moisture get mixed with the mercury, and must be expelled by boiling the mercury in the tube. It being essential that the mercury be quite freed from air and moisture, no barometer should be used till it has been well ascertained that this has been done. Some time after the instrument has been hung in an observing position, let it be inclined gently and with care, so that the mercury may strike against the top of the glass tube; if there is no air within, a sharp metallic click will be heard, but if the sound is dull, the air and moisture have not been entirely expelled. If the mercury should appear at any time to adhere somewhat to the tube and the convex surface assume a more flattened form, it may be concluded that air or moisture is present. If on examining the mercury with a lens minute bubbles are visible, air is present. In all these cases the instrument must be rectified.

The best barometers are usually fitted with an *air-trap*, originally proposed by Gay-Lussac for the purpose of arresting the ascent to the Torricellian vacuum of any air that may have found its way into the column by the cistern. The air-trap is fitted into the tube somewhere between the scale and the cistern. Barometers furnished with an air-trap can be conveyed from place to place with more safety, and they remain longer in good working order.

Siphon barometer. There are two classes of barometers—*Siphon Barometers* and *Cistern Barometers*. The *Siphon Barometer* (fig. 1) consists of a tube bent in the form of a siphon, and is of the same diameter throughout. A graduated scale passes along the whole length of the tube, and the height of the barometer is ascertained by taking the difference of the readings of the upper and lower limbs respectively. This instrument may also be read by bringing the zero point of the graduated scale to the level of the surface of the lower limb by means of a screw, and reading off the height at once from the surface of the upper limb. This barometer requires no correction for errors of capillarity or capacity. Since, however, impurities are contracted by the mercury in the lower limb, which is usually in open contact with the air, the satisfactory working of the instrument comes soon to be seriously interfered with.

Fig. 1.—Siphon Barometer.

Fig. 2.—Cistern Barometer.

Cistern barometer. Fig. 2 shows the *Cistern Barometer* in its essential and its simplest form. This barometer is subject to two kinds of error, the one arising from capillarity, and the other from changes in the level of the surface of the cistern as the mercury rises and falls in the tube, the latter being technically called the *error of capacity*. If a glass tube of small bore be plunged into a vessel containing mercury, it will be observed that the level of the mercury in the tube is not in the line of that of the mercury in the vessel, but somewhat below it, and that the surface is convex. The capillary depression is inversely proportional to the diameter of the tube. If the diameter of the tube be 0·1 inch, the capillary depression of mercury in boiled tubes, or *error of capillarity*, is 0·070 inch; if 0·2 inch, the error is 0·029 inch; if 0·3 inch, it is 0·014 inch; and if 0·5 inch, it is only 0·003 inch. Since capillarity depresses the height of the column, cistern barometers require an addition to be made to the observed height, in order to give the true pressure, the amount depending, of course, on the diameter of the tube.

The error of capacity arises in this way. The height of the barometer is the perpendicular distance between the surface of the mercury in the cistern and the upper surface of the mercurial column. Now, when the barometer falls from 30 to 29 inches, an inch of mercury must flow out of the tube and pass into the cistern, thus raising the cistern level; and, on the other hand, when the barometer rises, mercury must flow out of the cistern into the tube, thus lowering the level of the mercury in the cistern. Since the scales of barometers are usually engraved on their brass cases, which are fixed (and, consequently, the zero-point from which the scale is graduated is also fixed), it follows that, from the incessant changes in the level of the cistern, the readings would be sometimes too high and sometimes too low, if no provision were made against this source of error.

A simply way of correcting the error of capacity is—to ascertain (1) the neutral point of the instrument, or that height at which the zero of the scale is exactly at the height of the surface of the cistern, and (2) the rate of error as the barometer rises or falls above this point, and then apply a correction proportional to this rate. In many of the barometers used on the Continent the surface area of the cistern is 100 times greater than that of the tube, in which case the error is small, and can, besides, be easily cal culated. This is a good barometer for ordinary observers, inasmuch as no error arises in bringing the surface of the mercury of the cistern to the zero-point of the scale, which one requires to have some skill as a manipulator and good light to do correctly. Another way of getting rid of this error is effected by the *Board of Trade Barometer*, constructed originally by Adie of London. In this barometer the error of capillarity is allowed for in fixing the zero-point of the scale, and the error of capacity is obviated by making the scale-inches not true inches, but just so much less as exactly to counterbalance the error of capacity.

But the instrument in which the error of capacity is satisfactorily (indeed, entirely) got rid of is *Fortin's Barometer*. Fig. 3 shows how this is effected. The cistern is formed of a glass cylinder, through which the level of the mercury may be seen. The bottom is made like a bag, of flexible leather, against which a screw works. At the top of the interior of the cistern is a small piece of ivory, the point of which coincides with the zero of the scale. By means of the screw, which acts on the flexible cistern bottom, the level of the mercury can be raised or depressed so as to bring the ivory point exactly to the surface of the mercury in the cistern. In some barometers the cistern is fixed, and the ivory point is brought to the level of the mercury in the cistern by raising or depressing the scale. Fortin's barometer.

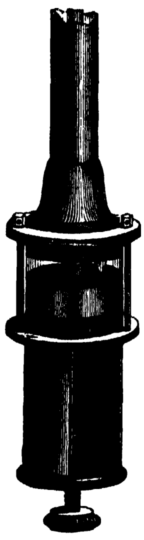

Fig. 3.—Fortin's Barometer.

What is called the *Fitzroy Barometer* is only a modified form of the siphon barometer, with the lower limb blown into a moderately-sized bulb, resembling a cistern in some respects, and thus giving a larger range to the readings of the upper limb. It is only suited for popular, not for scientific purposes. The common *Wheel Barometer*, the popular form of the *weather glass*, is also a modification of the siphon barometer. A small weight, glass or iron, floats on the mercury in the lower limb; to this weight a thread is attached, which is led round a horizontal axis, a small weight being suspended at its free extremity to keep it tight. The float rises and falls with the fluctuations of the barometer, and a pointer fixed to a horizontal axis being turned by this means indicates the height of the barometer by figures on a dial. Since the mercury only rises or falls in the open end of the siphon to the extent of half the oscillation, a cistern is added to the top of the upper limb to increase the amount of the oscillation in the lower limb. This form of the barometer is only suited for very rough purposes, since large and uncertain errors arise from the shortening and lengthening of the thread with the varying dampness or dryness of the air, and from the friction of the different parts of the mechanism of the instrument. Fitzroy barometer. Wheel barometer.

Since in working out the great atmospheric problem of the force of the wind in its relation to the barometric gradient (*i.e.*, the differences of the pressures at different places, reduced to the same level) readings from about the

hundredth of an inch (0·010), or even less, require to be observed and stated with great accuracy, the extreme importance of accurate sensitive barometers will be apparent,—instruments not only possessing a great range of scale, but a scale which will truly indicate the real atmospheric pressure at all times. The two barometers which best satisfy this requirement are *King's Barometer*, which has been in use for many years at the Liverpool Observatory, and *Howson's Barometer*. Fig. 4 shows the essential and peculiar parts of Howson's barometer. A is the barometer tube, which is of large diameter, and longer than ordinary in order to admit of a greater length of range. B is a movable cylindrical cistern, having attached to its bottom a long hollow tube or stalk c, hermetically sealed, springing to a height of about 28 inches above the fixed level of the mercury in the cistern. This stalk terminates a little below the upper level of the mercury, and its upper end is thus exposed to no more downward pressure than that of the mercury above it; consequently, there is an excess of upward pressure of the air which tends to raise the cistern. When the excess of upward pressure is exactly balanced by the weight of the cistern with its stalk and contained mercury up to *b*, an equilibrium will be established, which will keep the apparatus stationary or hanging in suspension. If now the atmospheric pressure acting on the cistern be increased, and if the thickness of the glass tube A be supposed to be nothing, the cistern would continue to ascend to an indefinite extent, since there is nothing to stop it. But as the glass is a substance of some thickness, mercury is displaced by the glass as it is plunged further into the cistern; and as it thus offers a resistance to the ascent of the cistern, the cistern will come to rest when the quantity of mercury displaced is equivalent to the increase of pressure. The extent of range which this barometer possesses over the ordinary barometer is determined by the ratio of the internal area of the tube A to that of the annulus of glass which bounds it,—the range increasing as the internal area is increased, or as the thickness of the glass is diminished.

Howson's barometer.

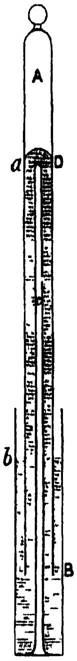

Fig. 4.—Howson's Barometer.

The liability of the barometer to be broken in carriage is great. This risk is considerably lessened in the *Board of Trade Barometer*, which has the tube very much reduced in diameter for a part of its length, breakage from "pumping" being so much lessened thereby that the instrument may be sent as a parcel by rail, if only very ordinary care be taken in the carriage. This is essentially the principle of the *Marine Barometer*, which, however, has the tube still more contracted. For rougher modes of transit an ingeniously constructed iron barometer has been invented by Mr T. Stevenson, C.E.

Sympiezometer.

The sympiezometer was invented by Adie of Edinburgh. It consists of a glass tube, with a small chamber at the top and an open cistern below. The upper part of the tube is filled with air, and the lower part and cistern with glycerine. When atmospheric pressure is increased, the air is compressed by the rising of the fluid; but when it is diminished the fluid falls, and the contained air expands. To correct for the error arising from the increased pressure of the contained air when its temperature varies, a thermometer and sliding-scale are added, so that the instrument may be adjusted to the temperature at each observation. It is a sensitive instrument, and well suited for rough purposes at sea and for travelling, but not for exact observation. It has been for some time superseded by the *Aneroid*, which far exceeds it in handiness, portability, and correctness. The *Aneroid Barometer* was invented by Vidi, and patented in England in 1844. Its action depends on the effect produced by the pressure of the atmosphere on a circular metallic chamber partially exhausted of air and hermetically sealed. Fig. 5 represents the internal construction, as seen when the face is removed, but with the hand still attached. *a* is a flat circular metallic box, having its upper and under surfaces corrugated in concentric circles. This box or chamber being partially exhausted of air, through the short tube *b*, which is subsequently made air-tight by soldering, constitutes a spring, which is affected by every variation of pressure in the external atmosphere, the corrugations on its surface increasing its elasticity. At the centre of the upper surface of the exhausted chamber there is a solid cylindrical projection *x*, to the top of which the principal lever *cde* is attached, as shown in the drawing. This lever rests partly on a spiral spring at *d*; it is also supported by two vertical pins, with perfect freedom of motion. The end *e* of the lever is attached to a second or small lever *f*, from which a chain *g* extends to *h*, where it works on a drum attached to the axis of the hand, connected with a hair spring at *h*, changing the motion from vertical to horizontal, and regulating the hand, the attachments of which are made to

Aneroid barometer.

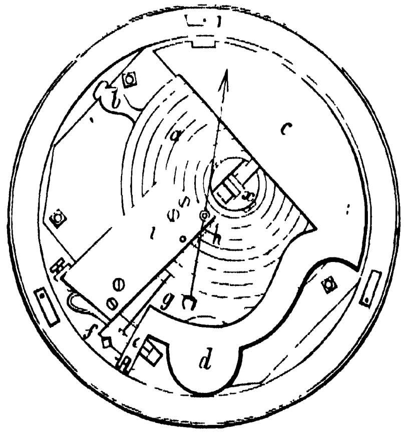

Fig. 5.—Aneroid Barometer.

the metallic plate *i*. The motion originates in the corrugated elastic box *a*, the surface of which is depressed or elevated as the weight of the atmosphere is increased or diminished, and this motion is communicated through the levers to the axis of the hand at *h*. The spiral spring on which the lever rests at *d* is intended to compensate for the effects of alterations of temperature. The actual movement at the centre of the exhausted box, from whence the indications emanate, is very slight, but by the action of the levers this is multiplied 657 times at the point of the hand, so that a movement of the 220th part of an inch in the box carries the point of the hand through three inches on the dial. The effect of this combination is to multiply the smallest degrees of atmospheric pressure, so as to render them sensible on the index.

The instrument requires, however, to be repeatedly compared with a mercurial barometer, being liable to changes from the elasticity of the brass chamber changing, or from changes in the system of levers which work the pointer. Though aneroids are constructed showing great accuracy in their indications, yet none can lay any claim to the exactness of mercurial barometers. The mechanism is liable to get fouled and otherwise go out of order, so that they may change 0·300 inch in a few weeks, or even indicate pressure so inaccurately and so irregularly that no confidence can be placed in them for even a few days, if the means of comparing them with a mercurial barometer be not at hand.

Self-registering barometers. Of the *self-registering barometers*, the best are those which accomplish this object by photography. This is done by concentrating the rays of a gas flame by means of a lens, so that they strike the top of the mercurial column. A sheet of prepared paper is attached to a frame placed behind a screen, with a narrow vertical slit in the line of the rays. The mercury being opaque throws a part of the paper in the shade, while above the mercury the rays from the flame pass unobstructed to the paper. The paper being carried steadily round on a drum at a given rate per hour, the height of the column of mercury is photographed continuously on the paper. From the photograph the height of the barometer at any instant may be taken. *King's*, *Hardy's*, *Hough's*, *Hipp's*, and *Thorell's self-registering barometers* may also be referred to as giving continuous records of the pressure. In all continuously registering barometers, however, it is necessary, as a check, to make eye-observations with a mercury standard barometer hanging near the registering barometer from four to eight times daily.

Materials. In constructing the best barometers three materials are employed, viz. :—(1) brass, for the case, on which the scale is engraved; (2) glass, for the tube containing the mercury; and (3) the mercury itself. Brass is the best material for the case and scale, inasmuch as its co-efficient of expansion is well known, and is practically the same though the alloy be not in all cases exactly alike. It is evident that if the co-efficient of expansion of mercury and brass were the same, the height of the mercury as indicated by the brass scale would be the true height of the mercurial column. But this is not the case, the co-efficient of expansion for mercury being considerably greater than that for brass. The result is that if a barometer stand at 30 inches when the temperature of the whole instrument, mercury and brass, is 32°, it will no longer stand at 30 inches if the temperature be raised to 69°; in fact, it will then stand at 30·1 inches. This increase in the height of the column by the tenth of an inch is not due to any increase of pressure, but altogether to the greater expansion of the mercury at the higher temperature, as compared with the expansion of the brass case with the engraved scale by which the height is measured. In order, therefore, to compare with each other with exactness barometric observations made at different temperatures, it is necessary to reduce them to the heights at which they would stand at some uniform temperature. The temperature to which such observations are now almost everywhere reduced is 32° Fahr.

The following is Schumacher's formula for computing the corrections for barometers, whose heights are noted in English inches, for temperature t, according to Fahrenheit's scale:

$$x = -h\frac{m(t-32°)-s(t-62°)}{1+m(t-32°)},$$

where h = height of barometer,

m = expansion of mercury for 1° Fahr. = 0·0001001,

s = expansion of brass for 1° Fahr. = 0·00001041.

The standard temperature of the English yard being 62° and not 32°, it will be found in working out the corrections from the above formula that the temperature of no correction is not 32° but 28°·5. If the scale be engraved on the glass tube, or if the instrument be furnished with a glass scale or with a wooden scale, different corrections are required. These may be worked out from the above formula by substituting for the co-efficient of the expansion of brass that of glass, which is assumed to be 0·00000498, or that of wood, which is assumed to be 0. Wood, however, should not be used, its expansion with temperature being unsteady, as well as uncertain.

If the brass scale be attached to a wooden frame and be free to move up and down the frame, as is the case with many siphon barometers, the corrections for brass scales are to be used, since the zero-point of the scale is brought to the level of the lower limb; but if the brass scale be *fixed* to a wooden frame, the corrections for brass scales are only applicable provided the zero of the scale be fixed at (or nearly at) the zero line of the column, and be free to expand upwards. In siphon barometers, with which an observation is made from two readings on the scale, the scale must be free to expand in one direction. Again, if only the upper part of the scale, say from 27 to 31 inches, be screwed to a wooden frame, it is evident that not the corrections for brass scales, but those for wooden scales must be used. No account needs to be taken of the expansion of the glass tube containing the mercury, it being evident that no correction for this expansion is required in the case of any barometer the height of which is measured from the surface of the mercury in the cistern.

Position of barometer. In fixing a barometer for observation, it is indispensable that it be hung in a perpendicular position, seeing that it is the *perpendicular distance* of the surface of the mercury in the cistern and that of the top of the column which is the true height of the barometer. Hence it is desirable that the barometer swing in position; or if this be attended with risk or inconvenience, it must be seen that it be clamped or permanently fixed in a position exactly vertical. The surface of the mercurial column is convex, and in noting the height of the barometer, it is not the chord of the curve,—an error not unfrequently made,—but its tangent which is taken. This is done by setting the straight lower edge of the vernier, an appendage with which the barometer is furnished, as a tangent to the curve. The vernier is made to slide up and down the scale, and by it the height of the barometer may be read true to 0·002 or even to 0·001 inch. See VERNIER.

In hanging a barometer the following points should be attended to:—(1), That it be hung so that the mercurial column be quite perpendicular; (2), that the scale be about 5 feet high, for facility of reading; (3), that the whole instrument, particularly the scale and the cistern, be hung in a good light; and (4), that it be hung in a position in which it will be exposed to as little fluctuation of temperature as possible. A wall heated by a flue, and positions which expose the instrument to the heat of the sun or to that of a fire, are very objectionable. It is to be kept in mind that no barometric observation can be regarded as good unless the *attached thermometer* indicates a temperature differing from that of the whole instrument not more than a degree. For every degree of temperature the attached thermometer differs from the barometer, the observation will be faulty to the extent of about 0·003 inch, which in discussions of diurnal range, barometric gradients, lunar range, and many other questions, is a serious amount.

Before being used, barometers should be thoroughly examined as to the state of the mercury, the size of cistern (so as to admit of low readings), and their agreement with some known standard instrument at different points of the scale. The pressure of the atmosphere is not expressed by the weight of the mercury sustained in the tube by it, but by the perpendicular height of the column. Thus, when the height of the column is 30 inches, it is not said that the atmospheric pressure is 14·7 lb on the square inch, or the weight of the mercury filling a tube at that height whose transverse section equals a square inch, but that it is 30 inches, meaning that the pressure will sustain a column of mercury of that height.

Barometric readings. The height of the barometer is expressed in English inches in England and America. In France and most European countries, the height is given in millimètres, a millimètre being the thousandth part of a mètre, which equals 39·37079 English inches. Up to 1869 the barometer

was given in half-lines in Russia, which, equalling the twentieth of an English inch, were readily reduced to English inches by dividing by 20. The metric barometric scale is now used in Russia. In a few countries on the Continent the French or Paris line, equalling 0·088814 inch, still continues to be used. Probably millimètre and English inch scales will soon be exclusively in use. The English measure of length being a standard at 62° Fahr., the old French measure at 61°·2, and the metric scale at 32°, it is necessary, before comparing observations made with the three barometers, to reduce them to the same temperature, so as to neutralize the inequalities arising from the expansion of the scales by heat.

The barometer is a valuable instrument as an indicator of coming weather, provided its readings be interpreted with intelligence. High pressures generally attend fine weather, but they not unfrequently accompany wet stormy weather; on the other hand, low pressures, which usually occur with wet and stormy weather, not unfrequently accompany fine mild weather, particularly in winter and in the northern parts of Great Britain. The truth is, the barometer merely indicates atmospheric pressure directly, whilst it indicates weather only inferentially. The chief points to be attended to are its fluctuations taken in connection with the wind and the state of the sky, but above all, the readings of the barometer as compared with those at neighbouring places, since it is *difference* of pressure, or the amount of the barometric gradient, which determines the strength of the wind and the weather generally.

Barometrical Measurements of Heights.

The decisive experiment by which Pascal established the reality of atmospheric pressure suggested to him the method of measuring heights by means of the barometer. The first attempts to effect this were necessarily rude and inaccurate, since they went on the assumption that the lower mass of air is of uniform density. The discovery, however, of the actual relation subsisting between the density of air and its elasticity by Boyle in England, and about the same time by Mariotte in France, laid a sure foundation for this branch of atmospheric physics —the relation being that, at the same temperature, the pressure of a gas is exactly proportional to its density.

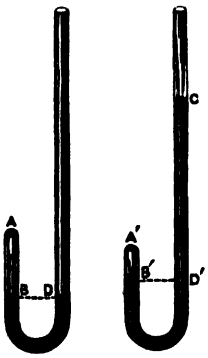

Fig. 1. Fig. 2.

The truth of this law may be shown by the following experiment. Take a glass tube, of equal bore throughout, closed at one end, and bent in the form of a siphon (fig. 1), and let us suppose that it contains in the closed limb a portion of air AB, shut off from the atmosphere by mercury filling the lower portion of the tube, and that the enclosed portion of air exists at the ordinary pressure of the atmosphere or 30 inches. In this case the mercury in each limb, being subject to the same pressure, will stand at the same level. If we now pour mercury into the long limb (fig. 2) till the level in this limb stands 30 inches above the level in the closed limb, the additional mercury will tend to compress the air in A′B′ with a pressure equal to that exerted by a column of 30 inches of mercury. In the latter case, therefore, the air is subjected to a pressure of two atmospheres, or 60 inches, while in the former it was only subjected to a pressure of one atmosphere or 30 inches. It will be found that the space A′B′ under the pressure of two atmospheres is only half the space AB where the pressure is only one atmosphere. If mercury had been filled in till the difference of level of the mercury in the two limbs was 60 inches, or a pressure of three atmospheres, the space occupied by the air in the closed limb would have been only a third of the original space when the pressure was only that of one atmosphere. Generally, Boyle's law or Mariotte's law is this:—The volume of a gas varies inversely as the pressure. Since the same quantity of air has been experimented with, it follows that the density is doubled with a pressure of two atmospheres, and trebled with that of three, and hence the pressure of a gas is proportional to its density.

This law, however, only holds provided the temperature is the same. The familiar illustration of a bladder, partially filled with air, expanding on being placed near a fire, shows that if the pressure remains the same,—the pressure in this case being that of the atmosphere,—the gas will occupy a larger space if its temperature be raised. If the temperature be increased and the air be confined so as to occupy the same space, the pressure will be increased.

The relation between the temperature and pressure of gases was first discovered by Gay-Lussac; and more recently our knowledge of this branch of the subject has been greatly enlarged by the beautiful and accurate experiments of Regnault. From those experiments it has been concluded that the co-efficient which denotes increase of elasticity for 1° Fahr. of air whose volume is constant equals ·002036; and that the co-efficient which denotes increase of volume for 1° Fahr. of air whose elasticity is constant equals ·002039. It may further be added that the co-efficient of expansion for carbonic acid gas, hydrogen, and all other gases, is as nearly as possible the same.

When a fluid is allowed to evaporate in the exhausted receiver of an air-pump, vapour rises from it until its pressure reaches a certain point, after which all further evaporation is arrested. This point depends on the nature of the fluid itself and on the temperature, and it indicates the greatest vapour pressure possible for the fluid at the particular temperature. Regnault has shown the amount of the vapour pressure of water at different temperatures, thus—

Temp. Fahr. °	Max. Pressure of Vapour. inch.	Temp. Fahr. °	Max. Pressure of Vapour. inch.
0	0·044	50	0·361
10	0·068	60	0·518
20	0·108	70	0·733
30	0·165	80	1·023
40	0·248	90	1·410

If gases of different densities be put into the same vessel it is found that they do not arrange themselves according to their densities, but are ultimately diffused through each other in the most intimate manner. Each gas tends to diffuse itself as in a vacuum, the effect of the presence of other gases being merely to retard the process of their mutual diffusion. As regards the atmosphere, evaporation goes on until the maximum vapour pressure for the temperature has been attained, at which point the air is said to be saturated, and whilst the temperature remains the same further evaporation is arrested. Thus, at a temperature of 50° evaporation goes on until the vapour pressure reaches 0·361 inch, but if the temperature were raised to 60° the process of evaporation would be renewed, and go on till the vapour pressure rose to 0·518 inch. If at a vapour pressure of 0·518 inch the temperature were to fall from 60° to 50°, the air would no longer be capable of retaining the whole of the aqueous vapour in suspension, but the surplus part would be condensed and fall as rain. In the change from the aeriform to the liquid state a quantity of latent heat is given out. The yet uncertain effect of these changes, particularly the change of form from the aeriform to the liquid state, on the pressure, temperature, and movements of the air, renders it peculiarly desirable that barometric observations for the determination of

heights should not be made when clouds are forming or rain is falling.

Dalton has shown[1] that air charged with vapour is specifically lighter than when it wants the vapour; in other words, the more vapour any given quantity of air has in it the less is its specific gravity; and Sir William Thomson has shown[2] that the condensation of vapour in ascending currents of air is the chief cause of the cooling effect being so much less than that which would be experienced by dry air. From these ascertained effects of aqueous vapour in modifying the pressure and temperature of the atmosphere, the importance in the barometric measurement of heights of full and accurate observations of the hygrometry of the atmosphere and of the weather will be apparent.

Since the equilibrium of the vapour atmosphere is being constantly disturbed by every instance of condensation, by the ceaseless process of evaporation, and by every change of temperature, and since the presence of oxygen and nitrogen greatly obstructs the free diffusion of the aqueous vapours, it follows that Dalton's law of the independent pressure of the vapour and the dry air does not absolutely hold good. From the constant effort of the vapour to attain to a state of equilibrium there is, however, a continual tendency to approach this state. Since the equal diffusion of the dry air and the vapour is never reached, observations can only indicate local humidity, and therefore as regards any considerable stratum of air can only be regarded as approximate. Though particular observations may often indicate a humidity wide of the mark, yet in long averages a close approximation is reached, except in confined localities which are exceptionally damp or dry. Hence in observations for the determination of heights, the results of a long-continued series of observations should be employed, and those hours should be chosen whose mean is near the daily mean.

The most recent results arrived at by Regnault are the best, but it is to be regretted that the whole subject of the hygrometry, both as regards the methods of observation and the methods of discussing the observations, is still in an unsatisfactory state. This consideration, taken in connection with our defective knowledge of the relation of aqueous vapour to radiant heat, of the mode of its diffusion both vertically and horizontally, and of the influence exerted by its condensation into cloud and rain, and with our ignorance of the merely mechanical effects of ascending, descending, and horizontal currents of air in increasing or diminishing barometric pressure, renders it evident that heights deduced from barometric observations can only be regarded as approximate. It is much to be desired, in stating results, that the limit of error were taken into account, and the nearest round number in accordance therewith should alone be given as the calculated result. Thus, it is a mistake to give as the height of a place 1999 feet when the calculation is based wholly on barometric observations, and the limit of error amounts to 30 feet or more. The height 2000 should be given as the result.

The correction for decrease of gravity at the higher station, as compared with the force of gravity at the lower station or at sea-level, must also be taken into account. Its amount is small, being, roughly speaking, only about 0·001 inch per 400 feet. Since the force of gravity is diminished in proportion to the square of the distance from the centre of gravity, the rate of its decrease with the height varies in different latitudes. Places at the equator being farther from the earth's centre than places at the poles, it follows that the force of gravity diminishes at a less rapid rate as we ascend at the equator than it does at the poles. Now, since at the equator gravity diminishes less rapidly with the height, the air at any given height will exert a higher pressure there than anywhere else on the globe at the same height as compared with what it does at the sea-level of the latitude. Hence a subtraction requires to be made at the equator, and the amount to be subtracted diminishes as we proceed into higher latitudes, till it falls to zero at latitude 45°, where the force of gravity is assumed to be the mean. For higher latitudes an addition is required which constantly increases till it reaches the maximum at the poles. This correction is also small, being for 1000 feet less than 0·001 inch in Great Britain, and less than 0·003 at the equator and the poles.

Various formulæ for the barometrical measurement of heights, based on these principles, have been given by Laplace and others, not a few of them being unnecessarily refined and intricate when the real character of the data is taken into consideration. The following formula by Rühlmann[3] is given as the simplest and best, being based on the most recent results which have been arrived at:—

$$h = 18400{\cdot}2\left(1{\cdot}00157 + 0{\cdot}003675\frac{t'+t''}{2}\right)\left(1 + 0{\cdot}378\frac{\frac{\sigma'}{b'}+\frac{\sigma''}{b''}}{2}\right)(1 + 0{\cdot}002623 \cos. 2\phi)\left(1 + \frac{2z+h}{6378150}\right)\log.\frac{b'}{b''} \quad . \quad . \quad . \quad . \quad . \quad (1),$$

in which h is the difference in mètres of level between the two stations; t' and t'' the temperature centigrade of the air at the two stations; b' and b'' the heights of the barometer in millimètres, corrected for temperature and for all instrumental errors; σ' and σ'' the elastic force of vapour; ϕ the mean of the latitudes of the two stations; and z the height of the lower station above the sea. Making—

$$A = \log.\left\{18400{,}2(1{\cdot}00157 + 0{\cdot}003675)\frac{t'+t''}{2}\right\},$$

$$C = \log.\left\{1 + \frac{0{\cdot}378}{2}\left(\frac{\sigma'}{b'} + \frac{\sigma''}{b''}\right)\right\},$$

$$D = \log.\{1 + 0{\cdot}002623 \cos. 2\phi\}$$

$$E = \log.\left\{1 + \frac{2z+h}{6378150}\right\}.$$

Rühlmann has calculated the values A, C, D, and E for the different values of the respective arguments, which are given in the tables appended to the work.

From formula (1) we obtain—

$$\log. h = \log.\{\log. b' - \log. b''\} + (A + C + D + E) \quad . \quad . \quad (2).$$

It is assumed that the whole stratum of air between the two heights is in a state of rest, and that the means of the temperature and humidity observed at the two stations are the means respectively of the stratum of air between them.

If great accuracy is desired, both barometers must be read from the zeros of their scales, and the observations must be corrected for all merely instrumental errors, and must be made strictly at the same time or times, seeing that a very small error, arising either from imperfect observations, or from their not being comparable, produces a comparatively large error in the calculated results.

In deducing heights from *long-continued observations* it should be ascertained that the barometers and observations are good, and observations should if possible be used which have been made at the same hours of the day and during the same years. Observations at different hours of the day are not comparable, since, owing to our imperfect knowledge of the differences of daily barometric range, the

[1] *Meteorological Observations and Essays*, 2d ed., p. 100.

[2] *Mem. Lit. and Phil. Soc. Manchester*, vol. ii. 3d series, p. 131.

[3] *Die Barometrischen Höhenmessungen und ihre Bedeutung für die Physik der Atmosphäre*, von Dr Richard Rühlmann, Leipsic, 1870.

necessity for the application of any so-called corrections for daily range must necessarily lead to error. The comparison should also only be between observations made during the same years, since the means of different years often differ widely from each other. Thus the difference of height between two places at which barometrical observations were made, from 1830 to 1859 and from 1850 to 1869 respectively, could be more accurately ascertained from the ten years' averages from 1850 to 1859 during which observations were made at both places, than from the longer averages of thirty and twenty years. Inattention to this point has often led to error, especially in cases where at one of the places only a few years were available. To secure greater accuracy, the calculations should be made on the mean for the year, the two extreme months, January and July, and that month during which the distribution of pressure is most uniform over the region where the places are situated. Owing to the great differences in the distribution of atmospheric pressure in different parts of the globe (see ATMOSPHERE), comparison of the observations at the higher station with those at more than one lower station is in some cases indispensable. Thus, if it were desired to compute the height of Dovre, in Norway, barometrically, it should be compared both with Christiania and with Christiansund on the west coast; for if compared with Christiania alone the calculated height would be too high, and if with Christiansund too low, the reason being that the mean annual pressure diminishes from Christiania to Christiansund. The same remark applies to a large portion of Hindustan and to many other regions of the globe.

The more special precautions to be taken in deducing heights from one or a few observations, that is, from such data as travellers observe, are these:—that the observations be made in as settled weather as possible at those hours of the day, at least, at which observations are made at the nearest meteorological stations, and be repeated as long as possible from day to day; that the barometer hang perpendicularly and in shade; and that the observations be not made till the whole instrument has acquired the temperature of the surrounding air. For, for every degree which the temperature indicated by the attached thermometer differs from the temperature of the whole instrument, there is an error of about 0·003 inch.

From their portability and handiness the aneroid barometer, and the thermometer for ascertaining the point at which water boils, are of great use in determining heights,—the thermometer, if properly managed, being the more accurate of the two. Since, owing to the sluggishness with which the aneroid often follows the changes of pressure, especially low pressures, its readings should not be recorded till it has hung for some hours at the place of observation, and if this be not possible, the time which elapsed from arriving at the place and making the observations should be stated. It may not be unnecessary to add that every opportunity which presents itself should be taken of comparing it with a standard mercurial barometer, owing to the variations, irregular or permanent, to which aneroids are subject, and that the instrument should always be read in one position, since the difference between the reading in a horizontal position and the reading in a vertical position is often considerable.

At a pressure of 29·905 inches distilled water boils at 212°. The temperature of the boiling point varies with the nature of the vessel. Thus, if the interior of the glass vessel be varnished with shell-lac, the temperature may rise to 221°; and if iron-filings be dropped into the water, the temperature is lowered. But in all these cases the temperature of the vapour arising from the water is as nearly as possible the same. Hence in making observations with the thermometer for hypsometrical purposes, the instrument is not plunged into the water, but the whole instrument, bulb and stem, are by an apparatus used for the purpose plunged into the vapour arising from the boiling water. The degrees on the thermometer used are greatly enlarged, thus admitting of a minute subdivision of the scale and, consequently, of very precise readings. The following are a few of the barometric heights corresponding to different temperatures at which distilled water boils, taken from Regnault's tables revised by Moritz:—

Boiling Point.	Barometer. inches.	Boiling Point.	Barometer. inches.
211°	29·331	205°	25·990
210	28·751	204	25·465
209	28·180	203	24·949
208	27·618	202	24·442
207	27·066	201	23·943
206	26·523	200	23·453

The temperature of the vapour of the boiling water being observed, the pressure is ascertained from the table, whence the height may be calculated, just as in the case of pressures obtained by means of a mercurial barometer.

The remark made by Sir John Leslie many years ago still holds good, that it is preposterous, in the actual state of physical science, to effect any high refinement in the formula for computing barometrical heights. What is required on the part of the computer of heights from barometrical observations is carefully to weigh the *limits of error* due to the instrument and methods of observations, to the hour of the day and the month of the year (see ATMOSPHERE, p. 28), and to the degree of unsettledness of the weather at the time the observations were made, and to give effect to these in the calculated results. From inattention to these simple considerations a large proportion of important heights given in works of travel and of physical geography are very erroneously stated, and consequently require careful revision.

For very rough approximations to the real height from observations of pressure and temperature, Sir G. B. Airy has prepared a table showing the differences of level corresponding to differences of pressure. It is from this table that the heights corresponding to pressures engraved on many aneroids are usually taken. The heights read off from the pressures should be corrected for observations of temperature carefully taken at the upper and lower stations, the mean of these two observations being assumed as the mean of the stratum of air occupying the interval between the two heights. (A. B.)

BARON. The origin and primary import of this term have been much contested. Menage derives it from the Latin *baro*, a word which we find used in classical Latin to signify "a simple" or "foolish man" (*Cic. Fin.*, ii. 23). Another form of the same word appears to be *varo*, to which Lucilius gives the meaning "a stupid man," "a blockhead," Forcellini observing that its primary sense is "a block of tough, hard wood." But with greater probability Graff derives the word baron from the old German *Bar = Mann, freier Mann.* The word seems related to the Spanish *varon*, which means "a male," "a noble person," and its root may be found in the Sanskrit *vêra*. Like the Greek ἀνήρ and the Latin *vir*, the word *baron* signifies man in general and also a *husband*—the old legal expression *baron* and *feme* being equivalent to our ordinary phrase "man and wife."

In modern English usage the term is particularly applied to a member of the lowest order of the peerage, but in ancient records (as Lord Coke observes) the barony included all the (titular) nobility of England, because all noblemen were barons though they might possess a higher dignity also; and the great council of peers, in which were included dukes, marquesses, and earls, as well as barons, was styled simply the "Council de Baronage." In like manner we

speak of the "barons wars," and "the barons" who signed Magna Charta, although nobles of higher rank joined in both, and it is usual in summoning to the Upper House a peer's son in the lifetime of the father to give, for the occasion, a separate existence to the latter's barony.[1] Thus Earl Fortescue sat in the House of Lords during his father's lifetime as baron of Castle Hill, county Devon—the barony held with his father's earldom. The fiction is still maintained when a commoner is raised directly to one of the higher grades of the peerage, as in the case of Admiral Jervis, who was created at the same time Baron Jervis and Earl St Vincent.

The origin and comparative antiquity of barons have been the subject of much research amongst antiquaries. The most probable opinion is that they were the same as our present lords of manors; and to this the appellation of *court-baron*, given to the lord's court, and incident to every manor, seems to lend countenance. The term baron had, therefore, originally a very extensive meaning, being applicable to all tenants-in-chief of the Crown, whether holding by knight service or by grand serjeantry. But the latter only were in the narrower sense the king's barons, and as such possessed both a civil and criminal jurisdiction, each in his *curia baronis*, and were entitled to seats in the great council of the nation. "For," says Sir H. Nicolas, "it was the principle of the feudal system that every tenant should attend the court of his immediate superior; and hence it was that he who held *per baroniam*, having no superior but the Crown, was bound to attend his sovereign in his great council or parliament, which was, in fact, the great court baron of the realm" (*Historic Peerage of England*, ed. Courthope, p. 18). The lesser barons—those, namely, who held by knight service—were also occasionally summoned to parliament, but upon no fixed principles, and "the irregularity of passing over many of them when councils were held for the purpose of levying money, led to the provision in the Great Charter of John, by which the king promises that they shall be summoned through the sheriff on such occasions" (Hallam, *Middle Ages*, iii. 213). Both these classes, but the former especially, might be entitled to the appellation of *Barons by Tenure;* but it is evident that the mere possession of a barony (*i.e.*, thirteen knights' fees and a quarter) did not give its possessor an absolute right to a seat in parliament, and, of course, all such baronies must have been swept away by the Act of 12 Car. II. c. 24, abolishing feudal tenures and whatever depended thereupon. But from the reign of Henry III. (49th year) the barons were summoned to attend the king in council or parliament *by writ*, and thus the dignity ceased to be territorial and became altogether personal. And although the writ, whether addressed to ancient barons or to those who had not before been peers of parliament, contained no words of limitation to the heirs of the person summoned, yet it was laid down by Coke, and has always been accepted, that it ennobles the blood of the person summoned, and that thus the barony becomes heritable by heirs, male or female. A further change by King Richard II. in the 11th year of his reign, when he created John Beauchamp de Holt baron of Kidderminster *by letters patent*, and since that date this mode of conferring the dignity of a baron has been pursued. Dugdale states that the solemn investiture of barons created by patent was performed by the king himself, by enrobing the peer in scarlet, and this form continued till 13 Jac. I., when the lawyers declared that the delivery of the letters patent without ceremony was sufficient. The letters patent express the limits of inheritance of the barony. The usual limit is to the grantee and heirs male of his body; occasionally (as in the case of Lord Brougham) in default of male issue, to a collateral male relative; and occasionally (as in the case of Lord Nelson) to the heirs of a sister. The coronation robes of a baron are the same as those of an earl, except that he has only two rows of spots on each shoulder; and, in like manner, his parliamentary robes have but two guards of white fur, with rows of gold lace; but in other respects they are the same as those of other peers. King Charles II. granted to the barons a coronet, having six large pearls set at equal distances on the chaplet. A baron's cap is the same as a viscount's. His style is *Right Honourable;* and he is addressed by the king or queen, *Right Trusty and Well Beloved.*

[1] The practice commenced, as Dugdale states, the 22 Edw. IV., but came into more general use in the latter part of the 17th century. It will be understood that it was designed to "accelerate the possession" of a dignity, and not to create a second.

Barons of the Exchequer, six judges (a chief baron and five puisne barons) to whom the administration of justice is committed in causes betwixt the king and his subjects relative to matters of revenue. Selden, in his *Titles of Honour*, conjectures that they were originally chosen from among the barons of the kingdom, and hence their name.

Barons of the Cinque Ports (originally Hastings, Dover, Hythe, Romney, and Sandwich) were (prior to 1831) members of the House of Commons, elected by the Cinque Ports, two for each port. Their right to the title is recognized in many old statutes, but in 1606 the use of the term in a message from the Lower House drew forth a protest from the peers, that "they would never acknowledge any man that sitteth in the Lower House to the right or title of a baron of parliament" (*Lords' Journals*). These ports are now under the jurisdiction of a *warden.*

Baron and Feme, in the *English Law*, a term used for husband and wife, in relation to each other, who are accounted as one person. Hence, by the old law of evidence the one party was excluded from being evidence for or against the other in civil questions, and a relic of it is still preserved in the criminal law.

Baron and Feme, in *Heraldry*, is when the coats-of-arms of a man and his wife are borne per pale in the same escutcheon,—the man's being always on the dexter side, and the woman's on the sinister. But in this case the woman is supposed not to be an heiress, for then her coat must be borne by the husband on an escutcheon of pretence. See HERALDRY. (C. J. R.)

BARONET, a name originally given to the *lesser barons* mentioned in the preceding article, but now confined to the lowest grade of our hereditary nobility. The order was instituted by King James I. in 1611, at the suggestion of Sir Robert Cotton, to whom the plan had been submitted by Sir Thomas Sherley of Wiston, its actual inventor. Originally, the creation of this order was merely an expedient to raise money, and the cost of a baronetcy in each case amounted to £1095, exclusive of the fees. The money thus raised was professedly destined for the defence and maintenance of the new plantation in the province of Ulster, but it actually passed at once into the king's exhausted exchequer. According to the instructions given to the commissioners appointed for admitting to the new dignity, none were eligible but "men of quality, state of living, and good reputation, worthy of the same, and, at the least, descended of a grandfather (by the father's side) that bore arms, and who have also of certain yearly revenue"—£1000 per annum. The number created at first was 200, and the king engaged for himself, his heirs, and successors, that this should not be exceeded; and for himself also promised that no vacancies in the original number should be filled up. Charles I. disregarded the stipulated limitation, and the original terms have never since been carried out. The first twenty patents issued

were dated 22d May 1611, and begin with that given to Sir Nicholas Bacon (son of the lord keeper), whose descendant still retains the position of premier baronet of England.

Baronets take precedence according to the dates of their patents, conformably to the terms of which no intermediate honour between baron and baronets can be established, and they rank above all knights except those of the Garter. The title or prefix of *Sir* is granted them by a peculiar clause in their patents, and until 1827 they could claim for themselves and the heirs male of their bodies the honour of knighthood. All baronets are entitled to bear in their coats-of-arms, either in a canton or an escutcheon at their choice, the arms of Ulster, viz., a bloody hand.

Baronets of Scotland, called also *Baronets of Nova Scotia*.—This order of knights-baronets was instituted by Charles I. in the year 1625, when the first person dignified with the title was Sir Robert Gordon of Gordonstone, a younger son of the earl of Sutherland. The professed object of the institution was to encourage the plantation and settlement of Nova Scotia in North America; hence the king granted to each of them a certain portion of land in that province, which they were to hold of Sir William Alexander, afterwards earl of Stirling, with precedency to them and their heirs-male for ever, before all knights called *equites aurati*, all lesser barons called *lairds*, and all other gentlemen, except Sir William Alexander, his Majesty's lieutenant in Nova Scotia, his heirs, their wives and children. It was further provided that the title of *Sir* should be prefixed to their Christian name, and *Baronet* added to their surname; and that their own and their eldest sons' wives should enjoy the title of *Lady*, *Madam*, or *Dame*. The baronets of Scotland had assigned to them as an addition to their armorial bearings the ensign of Nova Scotia, viz., argent, a cross of St Andrew, azure, to be borne in a canton or in escutcheon; but in 1629, after Nova Scotia was sold to the French, this privilege was changed into permission to wear a badge about their necks pendent from an orange-tawny silk ribbon.

Malone has given the following curious note upon this subject, in his learned *Life of Dryden*, prefixed to his edition of the prose works of that writer:—

"When the order of baronets was first established in 1611, King James engaged that they should not exceed two hundred. However, towards the close of his reign, that number being completed, and the creation of baronets being found a useful engine of Government (the courtier by whose influence the title was obtained receiving usually £1000 for the grant), it was not lightly to be parted with. A scheme, therefore, of creating *Baronets of Scotland* was devised, which, it was conceived, would be no infraction of the original compact to confine the grants to a limited number; and as the English baronets were created under the great seal of England, for the reduction of Ulster in Ireland, so the Scottish baronets were created under the great seal of Scotland, for the reduction of Acadia, or *Nova Scotia*. The scheme, however, was not carried into execution by King James; but early in the reign of his successor several Scottish baronets were made. From this statement it appears that there is no more necessity for calling a baronet created under the great seal of Scotland (whether he be an Englishman or Scotchman), a *Baronet of Nova Scotia*, than there is to denominate one created under the great seal of England a *Baronet of Ulster*."—(Malone's *Dryden*, vol. i. pp. 28, 29.)

After the Union with England in 1707 the baronets of Scotland charged their arms with the Ulster badge, being created as baronets of the United Kingdom.

Baronets of Ireland.—This order was likewise instituted by King James I. in the 18th year of his reign, for the same purpose and with the same privileges within the kingdom of Ireland as had been conferred on the analogous order in England; for which also the Irish baronets paid the same fees into the treasury of Ireland. (C. J. R.)

BARONIUS, CÆSAR, the great church historian, was born on the 31st October 1538 in the district of Naples. His parents, Camillo de Barono or Baronio and Porcia Trebonia, were of noble birth. He was educated at Veroli and Naples, where his favourite studies were theology and jurisprudence. In 1557 he accompanied his father to Rome, and found himself in the midst of the reactionary enthusiasm which did much to restore Italy, in spite of the efforts of her reformers, to the papal authority. There he was brought in contact with Philip Neri, a man who then and since has done much to reconcile the speculative student with the Church of Rome, and to provide for him work in her service to which he can give his whole heart. Neri had just founded the Italian Oratory, the model of many another, and he and his monks had vowed to devote themselves to student lives, and to dedicate their whole power of study to the Roman Catholic Church. Among the theological studies pursued in the oratory, church history and ecclesiastical biography held a prominent place, the greater part of every forenoon being set apart for these subjects In this small congregation Baronius found a congenial home, and his superior, Philip Neri, soon saw that he had secured a coadjutor who would make his oratory all he had hoped it would become. The alarm caused by the first Protestant church history, the *Magdeburg Centuries*, gave his studies a special direction, and, as he told Pope Sixtus V., he was urged by his own desires, and the encouragement of Neri, to attempt to answer the Magdeburg divines. This was the origin of the *Annales Ecclesiastici*, his great work, which occupied thirty laborious years. These *Annales*, the first and in many respects the most important historical work which the Roman Catholic Church has produced, begin with the birth of Christ and end with the year 1198. The book is not properly history; it is annals rather, as everything is subordinated to chronology. The year is first given, then the reigning Pope and the year of his reign, then the emperors of the East and West, and, after its institution, the name and year of the emperor of the Holy Roman empire. This chronological form had one advantage—theology was kept as much as possible in the background, and the facts of history were the most important part. The *Annales* have thus become very important to every student of church history whether Protestant or Roman Catholic. While Baronius was engaged in his great work he was encouraged by several marks of papal favour. He was named pronotarius of the papal chair; in 1596 he was elected a cardinal; and he was afterwards chosen to fill the much-coveted post of librarian of the Vatican. He died on the 30th of June 1607. The best and most useful edition of his works is that of Mansi, in 38 vols. fol.; it gives Pagi's *critica historico-theologica*, or corrections of Baronius, at the foot of each page The best text is the Antwerp edition of 1610.

BARQUISIMETO, a city of Venezuela, and since 1830 the capital of the province of Nueva Segovia, is situated on a confluent of the Portuguesa, which belongs to the northern part of the Orinoco system. The surrounding district is fertile, and produces excellent coffee, cocoa, and sugar, and the climate is healthy and pleasant. Barquisimeto was founded in 1522 by Juan de Villegas, principally for the exploration and working of gold mines supposed to exist in the neighbourhood, and at first it received the name of Nueva Segovia in honour of his native city. The commercial advantages of its situation soon raised it to considerable prosperity. In 1807 it had about 15,000 inhabitants; but on the 26th of March 1812, it was totally destroyed by an earthquake. It has since been regularly rebuilt, and, in spite of the disastrous effects of the revolutionary wars, has recovered its position. Among its public buildings may be mentioned a college and several schools. The inhabitants are partly engaged in the rearing of horses and mules. Population in 1873, 25,664.

BARR, a town in Alsace, 18 miles S.W. of Strasburg, situated on the eastern slope of the Vosges, at the mouth of the Ulrichthal. Wool and cotton spinning, and the manufacture of pottery, crystal, and soap, are its principal industries; and an active trade is carried on in wine, brandy, vinegar, cattle, and wood. The town is mentioned as early as the 8th century. It was burned by the troops of the Cardinal of Lorraine in 1592; in 1678 it suffered from a severe conflagration; and in 1794 it was greatly damaged by the explosion of the arsenal. There is a tepid mineral spring in the neighbourhood, and, on the Odilienberg, which rises above the town, are the ruins of the convent of St Odilia, which was founded in the 7th century. Population, 5651.

BARRA, or BARRAY (from the Scandinavian *Baraey*, isle of the ocean), one of the Hebrides or Western Isles of Scotland, forming part of Inverness-shire. It lies about 5 miles S.W. of South Uist, and is 8 miles in length by from 2 to 4 miles in breadth. The parish comprehends a number of smaller islands and islets, -Berneray, Flodday, Fluda, Hellisay, Mingalay, Watersay, &c.,—and is estimated to contain 4000 acres of arable land, and 18,000 of meadow and hill pasture. The cod, ling, and herring fisheries are considerable; and the coasts abound with shell-fish, especially cockles, which have sometimes afforded food to the inhabitants in times of famine. On Barra Head, the highest point of Berneray, is a lighthouse with an intermitting light 680 feet above high water, in lat. 56° 48′ N., long. 7° 38′ W. There are several remains of interest in the island of Barra, as the churches at Kilbar, the castle of the M'Neils at Kishmul, "Danish" forts and "Druidical" circles. Population of island (chiefly Gaelic-speaking Roman Catholics) in 1871, 1563; of the parish, 1753.

BARRACKPUR, a magisterial subdivision and town of British India, in the district of 24 Parganás, under the Lieutenant-Governor of Bengal. Barrackpur SUBDIVISION was formed in 1858. It consists of the single police circle of Nawábganj, and contains an area of 42 square miles, with 51 villages, 16,057 houses, and a total population of 68,629, of whom 47,709, or 69·5 per cent., are Hindus; 19,600, or 28·6 per cent., are Mahometans, 1281, or 1·9 per cent., are Christians; and 39 are of other religions. Proportion of males to total population, 52·2 per cent.; persons per square mile, 1626; villages per square mile, 1·21; persons per village, 1346; houses per square mile, 380; persons per house, 4·3. In 1870–71 the subdivision contained one magistrate's court, with a regular police of 195, and a village watch of 38 men. The separate cost of administration amounted to £2101.

BARRACKPUR TOWN and CANTONMENT, situated on the Húglí, 15 miles above Calcutta, in 22° 45′ 40″ N. lat., and 88° 23′ 52″ E. long.; area, 889 acres, or 1·39 square miles. Population, according to the experimental census of 1869—males, 5730; females, 2914; total, 8644. Population, as ascertained by the general census of 1872:—Hindus—males, 3207; females, 1745; total, 4952; Mahometans—males, 1987; females, 1561; total, 3548: Christians—males, 766; females, 297; total, 1063: others—males, 21; females, 7; total, 28. Total of all denominations—males, 5981; females, 3610; total in 1872, 9591. Municipal income in 1872, £235, 9s. 6d.; expenditure, the same; taxation, $5\frac{7}{8}$d. per head. Major Smyth says in his *Survey Report of the 24 Parganás District* (1857):—"The natives call it 'Chának,' from the circumstance of Job Charnock, the founder of Calcutta, having erected a bungalow and established a small bázár there [in 1689]. Troops were first stationed there in 1772, from which time it has acquired the name of Barrackpur. The cantonment is situated on the left bank of the Húglí; it has also a large bázár and several large tanks, and also a parade ground. There are usually four regiments of Native infantry cantoned in the lines. To the south of the cantonment is situated the park, created by the taste and public spirit of Lord Wellesley. Within the park is situated the Government House, a noble-looking building, commenced by Lord Minto, and enlarged into its present state by the Marquis of Hastings. The park is beautifully laid out, and contains a small menagerie." Its most interesting feature is now Lady Canning's tomb. Within the last few years commodious two-storied brick barracks have been constructed for the British troops, and have materially added to the health and comfort of the soldiers. The military bázár is situated a short distance from the Sepoy lines, and is carefully supervised by the authorities. The military force stationed in the cantonment, on the 1st March 1873, was as follows:—English troops, 18 officers, and 395 non-commissioned officers and rank and file; Native, 12 English and 21 Native officers, with 877 non-commissioned officers and men; total of all ranks, European and native, 1323.

Barrackpur played an important part in the two Sepoy mutinies of 1824 and 1857, but the details of these belong to the general history of British rule in India.

BARRACKS are groups of buildings constructed for the accommodation of soldiers. The word, which was formerly spelt "baracks" or "baraques," is derived from the Spanish "barracas," meaning the little huts or cabins used by the fishermen on the sea-shore, or for soldiers in the field. The French call them "casernes," meaning lodgings for soldiers. Barracks of a temporary character, commonly called "huts," have ordinarily been constructed by troops on a campaign as winter quarters, or when for any length of time in "standing camp,"—they being accommodated when in the field under other circumstances in tents, or else, if not provided with tents, bivouacing without cover.

In time of peace barracks were formerly only provided for troops in fortified places termed "garrisons," soldiers elsewhere being provided with quarters by being billeted on public-houses. The apprehension of disturbances, and risk of the troops being too much mixed up with the populations of the localities in which they might be stationed, mainly led to the construction of barracks in or near towns in England about the year 1792. In the first instance the Deputy-adjutant-general was charged with the building and fitting up of barracks. In 1793 the same officer was appointed "Superintendent-general of barracks," and subsequently "Barrack-master-general." In 1806 the barrack establishment was placed under the direction of a board of four commissioners, of whom one was generally a military man. About the year 1825 the duke of Wellington arranged for the construction and maintenance of barracks to be given over to the corps of Royal Engineers. The custody and equipment of barracks, with the supply of fuel and light to the troops quartered in them, were then made and remained, until recently, the duty of the "barrack department," which consisted of barrack-masters and barrack-sergeants.

The duties connected with barracks in the British service are now arranged as follows:—

Construction, maintenance, and supply of fixtures; also custody if dismantled..	Royal Engineer Department.
Equipment with supplies of all kinds, giving and taking over; also custody when furnished but unoccupied	Commissariat Department.
Distribution of troops to barracks	Q. M. General's Department, under the orders at head-quarters of the Field-Marshal Commanding-in-Chief, and in districts or at foreign stations of the General Officer Commanding.

The duties connected with the construction of barracks are under the supervision of the Inspector-general of Fortifications, who is also Director of Works to the War Department. He is assisted in these duties by a Deputy and two Assistant-directors of Works, and a professional staff.

The arrangement and composition of barracks vary according to the arm of the service to be accommodated in them; thus for the cavalry, horse and field artillery, Royal Engineer train, and transport branch of the army service corps, stables are required; and it is usual to provide for the unmarried non-commissioned officers and men over their horses, a troop of cavalry or a division of field artillery being placed in a separate block of two stories in height. Horse and field artillery also require gunsheds and workshops for artificers, such as collarmakers, wheelers, &c All mounted troops require forge and shoeing accommodation as well as saddlers' shops. Garrison artillery and companies of Royal Engineers can be accommodated in similar barracks to those for infantry, but the latter require an ample provision of workshops for artificers, with store accommodation for materials, &c.

Not fifty years since, in the West Indies, men slept in barracks in hammocks touching each other, only 23 inches of lateral space being allowed for each man. At the same time in England the men slept in wooden beds, with two tiers, like the berths of a ship, and not unfrequently each bed held four men. Now, each soldier has an iron bedstead which turns up in the middle, forming a seat for the day-time, and only two rows of beds are allowed in barrack-rooms, and the principle of providing one window for every two beds is carried out in all new barracks.

The best size for a barrack-room is now considered to be 60 or 62 feet long, by 20 feet wide, and about 12 feet high. The number of men each room is to contain is painted on the door; and in barracks of modern construction each barrack-room has attached to it—

(1.) A small (single) sergeant's room, with fire-place, cupboard, and small window looking into the men's room.

(2.) An ablution room, with basins, water-taps, and a fixed pan in which the feet can be washed.

(3.) A night urinal, with water for flushing laid on.

Barracks are washed once a week, and on intermediate days the rooms are dry-scrubbed. The walls and ceilings are limewashed by the troops twice a year. The general periodical painting of all barrack buildings is performed twice externally and once internally in every eight years. Formerly, barrack buildings were placed on very limited areas, and even a whole regiment was lodged in one house built in the form of a square, with the quarters of the officers on one side for the better supervision of the men; but the Barrack and Hospital Improvement Commission recommended that the men should be divided in numerous detached buildings, so placed as to impede as little as possible the movement of air and the action of the sun's rays.

For barracks, as a general rule, buildings of two stories in height are preferred to those of three stories, but three-story buildings may be adopted where space is limited and land very costly. Buildings of two stories are less expensive than those of only one story in height, and the general arrangement, when the former mode of construction is adopted, is more compact. The selection of a site for a barrack requires great care and circumspection. This duty is performed in the first instance by the Commanding Royal Engineer of the district, or an officer appointed by him; but the ground proposed is also reported on by an Army medical officer as well as subsequently by the General Officer commanding the district, the final approval resting with the Secretary of State for War.

The following important points have to be considered in the selection of a site, viz.:—(1.) That the ground is suitably situated; (2.) That it is sufficient for the number and nature of troops to be placed in the barracks; (3.) That it is not commanded by higher ground within range of rifle fire; (4.) That the subsoil is good and healthy; (5.) That water can be easily obtained for drinking, washing, and cooking; (6.) That drainage and sewerage can be carried out; (7.) That gas can be laid on.

A barrack should not as a rule be placed in the midst of a populous town, nor should it be too far distant from one. If in the midst of a town it would not be likely to be healthy or well placed in respect to keeping up discipline; if too far off the men quartered in it may become dissatisfied with the service. A barrack should be surrounded with a defensible wall; there should be as few entrances as possible, and these should be provided with strong, well-barred gates.

In the new barracks now under construction for brigade depôts, the armouries are generally placed in defensible "keeps," the outer or boundary walls being flanked by *caponnières*. In arranging the position of buildings on a design for a barrack, the axis of each of those intended for occupation by troops should be north and south, so as to allow the sun's rays to fall on both sides. One building should in no case obstruct the light from another. The distance of buildings should not be less than their own height from each other. The position selected for any new building or buildings in an existing or a proposed barrack is reported on by a board of officers, consisting of the head of the department, officer commanding a regiment, or other responsible officer who is to occupy the building when erected, an officer not under the rank of captain, and the commanding Royal Engineer or other engineer officer, a medical officer attending to advise the board. On the completion of a new building or barrack, it is also reported on by a board of officers before being taken over for occupation.

In 1854–55 public attention was called to the necessity for sanitary improvement in the barracks belonging to Great Britain, and an inquiry was instituted by the Barrack and Hospital Improvement Commission, which was succeeded by the Army Sanitary Committee. The result of the inquiries so made has been a great improvement of the quarters of the troops, which has tended largely to decrease the sickness previously prevalent among them.

The principal improvements have been as follows, viz.:—At least 600 cubic feet, and from 56 to 60 superficial feet, are now allotted to every single non-commissioned officer and man in permanent barracks, it being considered as important that a soldier should have his full ration of air as of food. In wooden huts 400 cubic feet are reckoned sufficient. At least 1000 cubic feet are allotted to every single non-commissioned officer and man in hot climates. About 1600 cubic feet are allotted to every horse, and since the introduction of ventilation as well as proper sanitary arrangements in stables, glanders have almost entirely disappeared from the army. Married non commissioned officers and men have special accommodation, with one or two rooms each, according to the size of the rooms or rank of the occupant. In the latest buildings small washing-rooms have been provided, in addition to two rooms for each family. A laundry and infant school are provided for every compound of married soldiers' quarters. The principal medical officer is now charged with seeing that the regulations for protecting the health of troops in barracks are carried out. Each regimental medical officer has also to see to this matter, as well as that every soldier has a separate bed; that the beds are placed at a proper distance from the wall, and are well aired; and that the windows are opened every morning. Barrack-rooms are warmed in two ways, viz., by radiant heat from an open fire, and by warm air obtained from an air chamber behind, and heated by the fire. Much attention has been paid of late years to the improvement of the means of cooking the meals of soldiers. Either steel boilers and Deane's ovens or "Warren's" apparatus are now ordinarily provided for this purpose. Every headquarter barrack now has a gymnasium and also a chapel school, as well as a sergeants' mess establishment. Besides a canteen with

a separate bar for the sale of groceries, one room is provided for recreation, with a coffee bar attached, and another room for reading, with a small book-room attached to it, where the library is stored, and from which books are issued. Where there are several barracks at the same station, the sick are usually treated in a garrison hospital; but where there is only one barrack, a regimental hospital forms a part of it. 1200 cubic feet are allowed at home for each patient treated in military hospitals, and about 1800 cubic feet in those constructed in hot climates. The proportion of hospital accommodation now allowed at home stations is 6 per cent. on the accommodation of the barrack or barracks to which such hospital is attached. A surgery, store accommodation, a separate infection ward, hospital sergeant's quarters, sick-orderly's rooms, and a mortuary, are provided as part of an hospital establishment. There is also, whenever practicable, a garden, where the convalescents can sit out, or take exercise in fine weather. At the main entrance to every barrack a regimental guard-room is placed, which, besides a good room for the guard. provided with a wooden bed on an iron frame, contains a prisoners' room, and also a few separate cells for the detention of such prisoners as require to be kept apart. A proportion of "provost cells" are also constructed in large barracks, where soldiers are confined when ordered or sentenced to imprisonment for short periods. In headquarter cavalry barracks a riding school, ordinarily 150 feet long and 50 feet wide, is provided; also one or more manèges for out-door training. In smaller barracks, for mounted troops only, manèges are provided for equitation exercise. Rifle ranges are now considered to be necessary adjuncts to all except small barracks, but sometimes the troops have to be moved to a distance for this purpose, owing to local difficulties preventing practice being carried on. In barracks of modern construction, a separate house or quarter containing about six rooms is provided for a commanding officer, and two rooms with a kitchen (or servant's room) for each field officer, or officer holding relative rank as such, and for each quarter-master. Other officers have one room each, with a compartment screened or curtained off for sleeping and dressing, a servant's room for brushing and cleaning being provided for every two or three officers. A mess establishment is attached to every officers' barrack, which is constructed in proportion to the numbers to be quartered in the barracks. Where the headquarters of a regiment are stationed, a billiard-room is usually allowed as part of the mess establishment. A good supply of water is one of the first requisites in a barrack, and it is preferable to obtain it, if possible, from the water-works of the locality, rather than from wells, which are liable to become polluted from soakage, leakage of drains, or other causes. Barracks should have high-level tanks to contain one or two days' supply of water, as a reserve, or in case of fire, and fire-cocks should be fixed in suitable places. Fire-engines, with an ample supply of hose and also ladders, are always supplied for use in barracks. The sewers or drains of a barrack should, if possible, discharge into the main or branch sewers of the locality, but if none such exist, irrigation of land may be resorted to, or earth closets can be adopted, and the liquid drainage only be disposed of by irrigation, or such other means as may be practicable. All drains should be properly trapped and ventilated. Soil-pipes of water-closets should also be ventilated by means of small pipes carried up above the roof of the main building; pipes of the size of ordinary gas-pipes will suffice for this purpose, allowing the escape of foul gas into the outer air. Overflow or other water-pipes should on no account be connected directly with a drain, but should discharge into an open or surface channel, or over a trap or grating. Gas is ordinarily laid on to barracks both externally and internally, the quantity consumed being checked by a meter or meters. It is usually obtained by agreement from any public gas-works in the locality, but at certain large stations the War Department have their own gas-works. At certain large stations where large bodies of troops are quartered, churches are provided in addition to or in place of chapel schools. The latter are used for the services of the men of different persuasions in succession, the former are sometimes similarly used, but are more generally restricted to the Church of England or other specific religious persuasion. Sometimes military cemeteries are provided, but more generally the soldiers are buried in those of the localities where they may be quartered. Wherever there is sufficient ground about or near a barrack, as at Eastney, near Portsmouth, soldiers may have portions for gardening allotted them.

The funds for the construction and maintenance of barracks are included in Vote 13 of the army estimates, and the average amounts so provided for them during the past three years have been as follows:—

Part 1, Works over £1000	£102,198
Part 2, New works and alterations under £1000...	68,040
Part 3, Ordinary and current repairs	210,455
	£380,693

The funds for the equipment of barracks are provided in Vote 12, for the departmental staff in Vote 9, and for supplies of fuel and light in Vote 10 of the army estimates. (C. B. E.)

BARRAS, Paul François Jean Nicolas, Comte de, a distinguished actor in the great French Revolution, was born in June 1755. He was a descendant of a noble family in Provence, and at an early age entered the army. He was twice in India with his regiment, but retired from the service after attaining the rank of captain. Like many others, he saw in the Revolution a good opportunity for retrieving his fortunes, which had been ruined by his extravagance and dissipation; and his penetration enabled him to foresee the certain fall of the royalist party. He threw in his lot with the revolutionists, and speedily distinguished himself by his vigour and hardihood. When elected a member of the National Convention, he gave an uncompromising vote for the king's death; and at the siege of Toulon, where for the first time he met Napoleon, his energetic measures contributed much to the success of the French arms. Robespierre, who hated Barras for his dissolute habits, and feared him for his boldness, endeavoured to have his name included in one of his prescription lists, but, on the 9th Thermidor 1794, Barras completely overthrew his power. His success from this period was secured; after the 13th Vendémiaire 1795, he was nominated general-in-chief; and after the affair of the 18th Fructidor 1797, in which Augereau played a prominent part, he was practically dictator. Bonaparte's *coup d'état* of the 18th Brumaire 1799 changed the whole aspect of affairs. Barras, seeing that resistance to his powerful protégé was useless, gave in his resignation, and retired to his country seat. His latter years were spent in various intrigues, in which he showed a strong leaning towards the royalist party. He died in 1829. The character of Barras has little in it that is worthy of admiration. He was dissolute in private life, and can scarcely be said to have had any definite public policy. At the same time he was courageous, prudent, and, on occasions, an able speaker.

BARRHEAD, a town of Scotland, county of Renfrew, three miles S. of Paisley, and 8 miles S.W. of Glasgow on the Caledonian Railway line between that city and Kilmarnock. It has rapidly increased since about 1840, and formed a junction with the neighbouring villages of Dovecothall, Cross Artherlie, and Grahamston. The principal employment is spinning, weaving, and bleaching. Population in 1871, 6209.

BARRI, Girald de, commonly called *Giraldus Cambrensis*, an historian and ecclesiastic of the 12th and 13th centuries, was born at the castle of Maenor Pyrr near Pembroke, probably in 1147. By his mother he was descended from the princes of South Wales, and the De Barris were one of the most powerful Welsh families. Being a younger brother, and intended for the church, he was sent to St David's, and educated in the family of his uncle, the bishop of that see. When about twenty years of age he was sent to the University of Paris, where he continued for some years, and, according to his own account, became an excellent rhetorician and lecturer. On his return in 1172 he entered holy orders, and was made archdeacon of Brecknock. Having observed with much concern that his countrymen the Welsh were very backward in paying tithes of wool and cheese, he applied to Richard, archbishop of Canterbury, and was appointed his legate in Wales for remedying this and other disorders. Barry excommunicated all, without distinction, who refused to compound matters with the church, and, in particular, delivered over bodily to the evil one those who withheld the tithes. Not satisfied with enriching, he also attempted to reform the clergy. He delated an aged archdeacon to the archbishop, for the unpardonable crime of matrimony;

and on his refusing to put away his wife he was deprived of his archdeaconry, which was bestowed upon the zealous legate. On the death of his uncle, the bishop of St David's, in 1176, he was elected his successor by the chapter; but this choice having been made without the permission and against the will of Henry II., Girald prudently declined to insist upon it, and went again to Paris to prosecute his studies. He speaks with exultation of the prodigious fame which he acquired by his eloquent declamations in the schools, and of the crowded audiences who attended them. Having spent about four years at Paris, he returned to St David's, where he found everything in confusion; and on the temporary retirement of the bishop, which took place soon after, he was appointed administrator by the advice of the archbishop of Canterbury, and governed the diocese in that capacity till 1184, when the bishop was restored. About the same time he was called to court by Henry II., appointed one of his chaplains, and sent into Ireland with Prince John, by whom he was offered the united bishoprics of Fernes and Leighlin. He would not accept them, and employed his time in collecting materials for his *Topography of Ireland*, and his history of the conquest of that island, which was completed in three books in 1187. In 1188 he attended Baldwin, archbishop of Canterbury, in his progress through Wales, preaching a crusade for the recovery of the Holy Land,—an employment in which he tells us, with his usual modesty, that he was far more successful than the primate, adding significantly, that the people were most affected with Latin sermons (which they did not understand), melting into tears, and coming in crowds to take the cross. On the accession of Richard I. in 1189, he was sent by that monarch into Wales to preserve the peace of the country, and was even joined in commission with William Longchamp, bishop of Ely, as one of the regents of the kingdom. He failed, however, to improve this favourable opportunity; and having fixed his heart on the see of St David's, the bishop of which was very old and infirm, he refused the bishopric of Bangor in 1190, and that of Llandaff the year following. But in 1192 the state of public affairs became so unfavourable to Barri's interest at court that he determined to retire. He proceeded to Lincoln, where William de Monte read lectures in theology with great applause; and here he spent about six years in the study of divinity, and in composing several works. At last the see of St David's, which had long been the object of his ambition, became vacant, and he was unanimously elected by the chapter, but met with so powerful an adversary in Hubert, archbishop of Canterbury, that it involved him in a litigation which lasted five years, cost him three journeys to Rome, and ended in his defeat in the year 1203. Retiring from the world, he spent the last seventeen years of his life in studious privacy. His MSS. are preserved in the British Museum, the library at Lambeth, and the Bodleian Library.

Of his published works, the best known is his *Itinerarium Cambriæ*, of which a translation, illustrated with annotations, and accompanied with a life of the author, was published by Sir Richard Colt Hoare, in two splendid quarto volumes, in 1806. The complete works are being published under the direction of the Master of the Rolls, with full introductions,—*Giraldi Cambrensis Opera*, edited by J. S. Brewer and Mr Dimock, 6 vols., 1861-75; the seventh and last volume has not yet appeared.

BARRINGTON, JOHN SHUTE, FIRST VISCOUNT, a nobleman distinguished for theological learning, was the youngest son of Benjamin Shute, merchant, and was born at Theobald, in Hertfordshire, in 1678. He received part of his education at the University of Utrecht; and, after returning to England, studied law in the Inner Temple. In 1701 he published several pamphlets in favour of the civil rights of Protestant dissenters, to which class he belonged. On the recommendation of Lord Somers, he was employed to induce the Presbyterians in Scotland to favour the union of the two kingdoms, and in 1708 he was rewarded for this service by being appointed to the office of commissioner of the customs. From this, however, he was removed on the change of adminstration in 1711; but his fortune had, in the meantime, been improved by the bequest of two considerable estates,—one of them left him by Francis Barrington of Tofts, whose name he assumed by Act of Parliament, the other by John Wildman of Becket. Barrington now stood at the head of the dissenters. On the accession of George I. he was returned member of parliament for Berwick-upon-Tweed; and in 1720 the king raised him to the Irish peerage, by the title of Viscount Barrington of Ardglass. But having unfortunately engaged in the Harburg lottery, one of the bubble speculations of the time, he incurred the disgrace of expulsion from the House of Commons in 1723,—a punishment which was considered greatly too severe, and was thought to be due to personal malice on the part of Walpole. In 1725 he published his principal work, entitled *Miscellanea Sacra, or a New Method of considering so much of the History of the Apostles as is contained in Scripture, in an Abstract of their History, an Abstract of that Abstract, and four Critical Essays*, 2 vols. 8vo,—afterwards reprinted with additions and corrections, in 3 vols. 8vo, 1770, by his son, the bishop of Durham. In the same year he published *An Essay on the Several Dispensations of God to Mankind*. He was the author of various other tracts, chiefly on subjects relating to religious toleration. He died in 1734. Of his large family four were distinguished.

The eldest, WILLIAM WILDMAN, second Viscount Barrington (born 1717, died 1793), held important Government offices. From 1755 to 1761 he was secretary at war, from 1761 to 1762 chancellor of the exchequer, from 1762 to 1765 treasurer of the navy, and from 1765 to 1778 secretary at war again. He resigned in that year, receiving a handsome pension. In 1782 he held office for a short time as postmaster-general.

The Hon. DAINES BARRINGTON, the third son, born in 1727, was a distinguished antiquary and naturalist. He was educated for the profession of the law, and after filling various posts, was appointed a Welsh judge in 1757, and afterwards second justice of Chester. He never rose to much eminence at the bar, but he showed his knowledge of the law as a subject of liberal study by a valuable publication, entitled *Observations on the Statutes, chiefly the more ancient, from Magna Charta to 21st James I. cap. 27, with an Appendix, being a proposal for new-modelling the Statutes*, 1766, 4to, a work which has a high reputation among historians and constitutional antiquaries. In 1773 he published an edition of Orosius, with Alfred's Saxon version, and an English translation with original notes. His *Tracts on the Probability of reaching the North Pole*, 1775, 4to, were written in consequence of the northern voyage of discovery undertaken by Captain Phipps, afterwards Lord Mulgrave. In them he has accumulated a variety of evidence favourable to his own opinion of the practicability of attaining the object in which that voyage had failed; and it is not improbable that his views and arguments had some effect in determining the Government at a later period to renew the attempt. Mr Barrington's other writings are chiefly to be found in the publications of the Royal and Antiquarian Societies, of both of which he was long an assiduous member, and of the latter vice-president. Many of these were collected by him in a quarto volume entitled *Miscellanies on various Subjects*, 1781. Among the most curious and ingenious of his papers, are his *Experiments and Observations on the Singing of Birds*, and his *Essay on the Language of Birds*. He

died on the 14th March 1800, and was buried in the Temple church.

SAMUEL BARRINGTON, the fourth son, was born in 1729, and died in 1800. He entered the navy at an early age, and in 1747 had worked his way to a post-captaincy. He was distinguished for his bravery and skill, and in 1778 attained the rank of rear-admiral. He held command for some time in the West Indies, and repulsed a superior French force at Sta Lucia.

SHUTE BARRINGTON, the youngest son, was born in 1734, and died in 1826. He was educated at Eton and Oxford, and after holding some minor dignities, was made bishop of Llandaff in 1769. In 1782 he was translated to Salisbury, and in 1791 to Durham. He published several volumes of sermons and tracts, and wrote the political life of his brother, Viscount Barrington.

BARRISTERS, in England, are the highest class of lawyers who have exclusive audience in all the superior courts. Every barrister must be a member of one of the four ancient societies called Inns of Court, viz., Lincoln's Inn, the Inner and Middle Temples, and Gray's Inn. The existence of these societies as schools can be traced back to the 13th century, and their rise is attributed to the clause in Magna Charta, by which the Common Pleas were fixed at Westminster instead of following the king's court, and the professors of law were consequently brought together in London. Associations of lawyers acquired houses of their own in which students were educated in the common law, and the degrees of barrister (corresponding to apprentice or bachelor) and sergeant (corresponding to doctor) were conferred. These schools of law are now represented by the Inns of Court, which still enjoy the exclusive privilege of calling to the bar, and through their superior order of *benchers* control the discipline of the profession.

Every person not otherwise disqualified may be admitted as a student of law by passing a general examination in London, or on producing evidence of his having passed a public examination at a university. The year is divided into four terms, and every student must keep twelve terms before he can be called to the bar. A term is kept by the student's dining six (if a university man, three) times in the hall of his society. Until quite recently the Inns of Court exercised little or no supervision over the legal education of their students. Any student who had duly kept his terms might be admitted to the bar on producing either a certificate of having passed the general examination of the Council of Legal Education, or a certificate of attendance at certain public lectures, or of having read in the chambers of a barrister or special pleader for at least twelve months. The examination not being compulsory, was only used as a qualification for call by a minority of students, and neither of the other tests afforded any security as to the applicant's fitness for admission. The regulations both as to legal education and examinations have been very greatly altered. A complete staff of public lecturers and tutors has been established, and every student must pass an examination in jurisprudence, civil and international law, and English law, before being admitted to his call. Persons connected with the law in any inferior capacity (such as that of solicitor and solicitor's clerk), or with trade, will not be admitted as students; and the benchers, besides, have the right of rejecting any applicant with or without cause assigned. For sufficient reasons, and subject to an appeal to the Common Law judges as visitors, they may reject the petition of a student to be called to the bar, or expel from their society and from the profession any barrister or bencher of the inn. This power has been exercised in several cases within recent years, and the benchers appear to take cognizance of any kind of misconduct, whether professional or not, which they may deem unworthy of the rank of barrister. The age at which a student may be called to the bar is twenty-one years.

The peculiar business of barristers is the advocacy of causes in open court, but in England a great deal of other business falls into their hands. They are the chief conveyancers, and the *pleadings* (*i.e.*, the counter statements of parties previous to joining issue) are in all but the simplest cases drafted by them. There is, indeed, a separate class of *conveyancers* and *special pleaders*, being persons who have kept the necessary number of terms qualifying for a call, but who, instead of being called, take out licences to practise *under the bar*. There are still a few persons who act under such special licences, but in general conveyancing and special pleading form part of the ordinary work of a junior barrister. The highest rank among barristers is that of king's or queen's counsel. They lead the case in court, and give opinions on cases submitted to them, but they do not accept conveyancing or pleading, nor do they admit pupils to their chambers. Precedence among queen's counsel, as well as among outer barristers, is determined by seniority. The order of sergeants at law still exists, but no new appointments have recently been made, and it will probably be allowed to become extinct, the title of queen's counsel being generally preferred. Sergeants rank after queen's counsel. Although every barrister has a right to practise in any court in England, it will be found, in fact, that each special class of business has its own practitioners, so much so indeed, that the bar may almost be said to be divided into several professions. The most marked distinction is that between barristers practising in Chancery and barristers practising in the courts of Common Law. The fusion of Law and Equity contemplated by the Judicature Act, 1873, may be expected in course of time to break down this distinction; but for many years there has been a complete separation between these two great branches of the profession. There are also subordinate distinctions in each branch. Counsel at Common Law attach themselves to one or other of the circuits into which England is divided, and may not practise elsewhere unless under special conditions. In Chancery the queen's counsel for the most part restrict themselves to one or other of the courts of first instance (those of the Vice-Chancellors or Master of the Rolls). Business before the court of Admiralty, the court of Probate and Divorce, the Privy Council, and parliamentary committees, exhibits, though in a less degree, the same tendency to specialization. In some of the larger provincial towns there are now local bars of considerable strength. In Manchester and Liverpool alone there are believed to be between seventy and eighty practising barristers; and the probable extension of this system cannot fail to have a most important influence on the future character of the profession. The bar of Ireland exhibits in its general arrangements the same features as the bar of England. Every Irish barrister must have kept at least six terms in one of the English Inns of Court. There is no connection whatever between the Scotch and English bars.

Counsel is not answerable for anything spoken by him relative to the cause in hand and suggested in the client's instructions, even though it should reflect on the character of another and prove absolutely groundless, but if he mention an untruth of his own invention, or even upon instructions if it be impertinent to the matter in hand, he is then liable to an action from the party injured. Counsel may also be punished by the summary power of the court or judge as for a contempt, and by the benchers of the inn to which he may belong on cause shown.

The rank of barrister is a necessary qualification for nearly all offices of a judicial character, and a very usual

qualification for other important appointments. Not only the judgeships in the Superior Courts of Law and Equity at home and in the colonies, but nearly all the magistracies of minor rank—recorderships, county court judgeships, &c., —are restricted to the bar. The result is a unique feature in the English system of justice, viz., the perfect harmony of opinion and interest between the bar as a profession and all degrees of the judicial bench.

Revising Barristers are counsel of not less than seven years' standing appointed to revise the lists of parliamentary voters.

Barristers cannot maintain an action for their fees, which are regarded as gratuities, nor can they, by the usage of the profession, undertake a case without the intervention of an attorney.

BARROS, JOAO DE, a celebrated Portuguese historian, was born about 1496, and died in 1570. In 1522 he was appointed governor of St George del Mina, on the coast of Guinea. Three years after, the king recalled him to court, and made him treasurer of the Indies. This appointment furnished him with the materials necessary for the composition of his valuable history, entitled *Asia Portuguesa*, the first decade of which he published in 1552, the second in 1553, and the third in 1563; the fourth was not published till 1615. Several authors have continued the work, so that it extends to twelve decades. The best edition is that published at Lisbon, in 1778, in 9 vols 8vo.

BARROW-IN-FURNESS, a borough, port, and parish in the hundred of Lonsdale, North-West Lancashire, situated opposite the island of Walney, at the extreme point of the peninsula of Furness, which lies between Morecambe Bay and the estuary of the Duddon. It is distant 35 miles from Lancaster and 91 from Carlisle. The area of the borough, which includes Walney and the islets at its south end, is 17,000 acres, of which 8155 are land, the rest being sand and water.

The town has had a remarkable rise. The veins of pure hæmatite iron ore in the district, now so extensively wrought, have long been in repute; and more than a hundred years ago, a small traffic was carried on in the ore, with the addition by-and-by of pig-iron, which early began to be manufactured in the vicinity of the mines,—the branch of the channel, now converted into docks, serving as a harbour, and the beach as a quay, for the shipment of the material brought down from the mines and charcoal furnaces. But at the beginning of the present century the annual export was only about 1000 tons, and then, and for many years after, though the trade went on increasing, the place was the merest hamlet, the population so recently as 1847 being only 325. It may be said that the railway has created the modern town. By the opening in 1846 of the first short section of the Furness Company's line, from the mines near Dalton to Piel pier and Barrow, the trade of the district received a great impetus, and it rapidly developed with the various extensions of the railway, till in 1857, by the carrying of the line over Morecambe sands, through communication was established between Barrow and Carnforth. When the railway was opened the shipments of ore had risen to 60,000 tons a year, while within five years afterwards there left by sea and rail a total of 250,000, which again, within other five years, increased to 450,000 tons. The next great onward step was the establishment at Barrow, in 1859, of the iron-works of Messrs Schneider and Hannay, followed in 1864 by the commencement of steel-works, the two being united in 1866 under "The Barrow Hæmatite Steel Company (Limited)." In 1867 there were opened the Devonshire and Buccleuch docks, constructed at a comparatively small cost by the enclosure of the channel between the mainland and a small island on which shipbuilding works have since been erected. The docks comprise an area of above 60 acres, are entered from Walney Channel by a gateway 60 feet wide, give a uniform depth of 24 feet, the stone quays being 1½ miles long, and the wharves supplied with hydraulic cranes, one of which is capable of lifting 100 tons. Within a few years after the opening of the docks various important branches of industry were introduced, by means of which the town has both been consolidated and increased. The census of 1871 gives a return of 17,992, while a census for municipal purposes, November 1874, showed a population of over 40,000. The inhabited houses at the same period numbered about 6000, the rateable value of the borough being £144,000. The town owes much of its prosperity to the enterprise of the dukes of Devonshire and Buccleuch, and also to the foresight, zeal, and practical ability of Sir James Ramsden, managing director of the Furness Railway Company and first mayor of the borough, who in 1872 received the honour of knighthood as an acknowledgment of the value of his work, while a massive bronze statue in the centre of the town, raised about the same time by voluntary contributions, testifies to the appreciation of his services by the community.

A great part of the town lies low, much of it being built on ground reclaimed from the sea. It is well laid out, according to a fixed plan, in regular streets running at right angles, viz., north and south, and east and west. About £19,000 have already been expended on approaches and general road improvements. Not many public buildings can be looked for, but among others are the North Lonsdale Hospital; the Workmen's Club and Institute, the gift of Mr H. W. Schneider, and others; swimming baths, presented by Sir James Ramsden; a town-hall and large covered market, besides churches, schools, and banks.

The first place among the public works must be assigned to those of the Barrow Hæmatite Steel Company. Their iron-works have sixteen blast furnaces constructed so as to save the waste gases, which are utilized in heating the boilers and hot-air ovens. At the steel-works, which are the largest in Great Britain, are eighteen converters for making Bessemer steel. The amount of ore used is about 460,000 tons annually, of which the company's own mines yield upwards of 350,000 tons. There is an annual produce of 250,000 tons pig-iron, and 110,000 tons of steel, 80,000 tons of the latter being rails. In the processes about 500,000 tons of coke and coal are consumed annually; and the company employ at their works and iron-mines nearly 5000 men, besides a large number at coal-mines which they also work.

The works of the Iron Shipbuilding Company (capital, a quarter of a million), lying between the docks and Walney Channel, cover an area of 50 acres, with a frontage of 1050 feet, where ten vessels of the largest size can be laid down. When the works are in full operation, 6000 men will be employed. There is also a graving-dock of the largest size.

The Barrow Flax and Jute Company have an extensive jute work adjoining the docks, and communicating with the railway. It covers an area of 14 acres, has an imposing and attractive exterior, and is beautifully and elaborately fitted up with the greatest possible regard to efficiency and comfort. The works employ 2000 hands. Besides the above there are large engineering-works, waggon-works, saw-mills, brick-works, and a steam corn-mill.

The trade of the port is indicated by the character of the public works. The imports are chiefly timber, coal, jute, and general produce. Ore, steel rails, and pig-iron are chief among the exports. In 1874 the vessels entering the port numbered 1620, with a tonnage of 347,800 tons register. An extension of dock accommodation is being provided in a series of basins, to be called the Ramsden dock, with a water area of 200 acres. Passenger

steamers run daily to Belfast, and there is also a regular service to Glasgow and to the Isle of Man. By rail there is connection with Whitehaven, and with the London and North-Western and Midland systems, with branches to the Lake district.

Barrow is in the diocese of Carlisle. Besides the Church of England, which has three places of worship, there are the following churches:—the Presbyterian, Congregational, Wesleyan, Methodist New Connexion, Baptist, and Primitive Methodist.

The town received a charter of incorporation in 1867, when a council of sixteen was nominated, that number being doubled by an Act obtained in 1875. The supply of water comes from Kirkby Moor, the water-works as well as the gas-works being the property of the corporation. A cemetery has been provided at a cost of £25,000, with three chapels. A complete and thorough plan of drainage is being carried out, partly on the separate system. There is a fire brigade under the corporation, and at the entrance to the harbour there is a life-boat station. The police are those of the county. Several newspapers are published; and there are branches of various banking establishments, some of them occupying large and handsome buildings.

The extensive and interesting ruins of Furness Abbey, founded by Stephen in 1127, lie within the borough, over two miles from the heart of the town. They are beautifully situated in a small wooded valley, with a hotel and railway station close by. On Piel island is the Pile of Fouldrey, or Piel castle, the ruin of a castle built in 1327 by the abbot of Furness.

BARROW, Isaac, an eminent mathematician and divine, was the son of Thomas Barrow, a linen draper in London, where he was born in 1630. He was at first placed for two or three years at the Charter-house school. There, however, his conduct gave but little hopes of his ever succeeding as a scholar, for he was inattentive and extremely fond of fighting. But after his removal from this establishment, his disposition took a happier turn; and having soon made considerable progress in learning, he was in 1643 entered at St Peter's College, and afterwards at Trinity College, Cambridge, where he applied himself with great diligence to the study of literature and science, especially of natural philosophy. He at first intended to adopt the medical profession, and made some progress in anatomy, botany, and chemistry, after which he studied chronology, geometry, and astronomy. He then travelled in France and Italy, and in a voyage from Leghorn to Smyrna gave proofs of great personal bravery; for the ship having been attacked by an Algerine pirate, Barrow remained upon deck, and fought with the utmost intrepidity, until the pirate, unprepared for the stout resistance made by the ship, sheered off and left her to pursue her voyage.

At Smyrna he met with a most kind reception from the English consul, Mr Bretton, upon whose death he afterwards wrote a Latin elegy From this place he proceeded to Constantinople, where he received similar civilities from Sir Thomas Bendish, the English ambassador, and Sir Jonathan Dawes, with whom he afterwards contracted an intimate friendship. While at Constantinople he read and studied the works of Chrysostom, once bishop of that see, whom he preferred to all the other Fathers. He resided in Turkey somewhat more than a year, after which he proceeded to Venice, and thence returned home through Germany and Holland in 1659. Immediately on his reaching England he received ordination from Bishop Brownrig, and in 1660 he was appointed to the Greek professorship at Cambridge. When he entered upon this office he intended to have prelected upon the tragedies of Sophocles; but he altered his intention, and made choice of Aristotle's rhetoric. His lectures on this subject having been lent to a friend who never returned them, are irrecoverably lost. In July 1662 he was elected professor of geometry in Gresham College, on the recommendation of Dr Wilkins, master of Trinity College, and afterwards bishop of Chester; and in May 1663 he was chosen a fellow of the Royal Society, at the first election made by the council after obtaining their charter. The same year the executors of Mr Lucas, who, according to the terms of his will, had founded a mathematical chair at Cambridge, fixed upon Barrow as the first professor, and although his two professorships were not inconsistent with each other, he chose to resign that of Gresham College, which he did on the 20th May 1664. In 1669 he resigned his mathematical chair to his illustrious pupil Isaac Newton, having now determined to renounce the study of mathematics for that of divinity. Upon quitting his professorship Barrow was only a fellow of Trinity College; but his uncle gave him a small sinecure in Wales, and Dr Seth Ward, bishop of Salisbury, conferred upon him a prebend in that church. In the year 1670 he was created doctor in divinity by mandate; and, upon the promotion of Dr Pearson, master of Trinity College, to the see of Chester, he was appointed to succeed him by the king's patent, bearing date the 13th February 1672. In 1675 Dr Barrow was chosen vice-chancellor of the university. He died on the 4th of May 1677, in the 47th year of his age, and was interred in Westminster Abbey, where a monument, surmounted by his bust, was soon after erected by the contributions of his friends. By his English contemporaries Barrow was considered a mathematician second only to Newton. Continental writers do not place him so high, and their judgment is probably the more correct one. He was undoubtedly a clear-sighted and able mathematician, who handled admirably the severe geometrical method, and who in his *Method of Tangents* approximated to the course of reasoning by which Newton was afterwards led to the doctrine of Ultimate Ratios; but his substantial contributions to the science are of no great importance, and his lectures upon elementary principles do not throw much light on the difficulties surrounding the border-land between mathematics and philosophy. His *Sermons* have long enjoyed a high reputation; they are weighty pieces of reasoning, elaborate in construction and ponderous in style.

His scientific works are very numerous. The most important are:—1. *Euclid's Elements*; 2. *Euclid's Data*; 3. *Optical Lectures*, read in the public school of Cambridge; 4. *Thirteen Geometrical Lectures*; 5. *The Works of Archimedes, the Four Books of Apollonius's Conic Sections, and Theodosius's Spherics, explained in a New Method*; 6. A *Lecture*, in which Archimedes's Theorems of the Sphere and Cylinder are investigated and briefly demonstrated; 7. *Mathematical Lectures*, read in the public schools of the University of Cambridge. The above were all written in Latin. His English works have been collected and published in four volumes folio.

BARROW, Sir John, Bart., was born near Ulverston, in Lancashire, June 19, 1764. His early opportunities of instruction were limited; but by self-education he matured those powers which eventually were turned to so good an account. He displayed at an early age a decided inclination for mathematical pursuits. He passed some years of his youth as superintending clerk of an iron foundry at Liverpool, and he afterwards taught mathematics at an academy in Greenwich. While in the latter situation he was fortunate in obtaining, through the interest of Sir George Staunton, a place in the first British embassy to China. He was thus enabled to put his foot on the first step of the ladder of ambition; but each step in his subsequent career may be fairly said to have been achieved by himself. The account of the embassy published by Sir George Staunton records many of Barrow's valuable contributions to literature and science connected with China. This work, together with his own subsequently published volume of

travels, is ample evidence how well his time had been employed. Few persons could, within the space of a few months, overcome all the practical difficulties of such a language as the Chinese; but Barrow soon began to converse in it, and acquired a complete knowledge of its theory. His papers on this subject in the *Quarterly Review* (to which periodical he was for many years a very frequent contributor) contain a very admirable account of that singular language.

Although Barrow ceased to be personally connected with Chinese affairs after the return of the embassy in 1794, he always continued to take a lively interest in them, and on critical occasions was frequently consulted by the British Government. His services were secured by Lord Macartney in his important and delicate mission to settle the government of the newly-acquired colony of the Cape of Good Hope. Barrow was entrusted with opening communications with the Kaffres, in which he displayed a spirit, judgment, and humanity, which unfortunately were less conspicuous in subsequent transactions with those tribes. The two volumes of his history of the colony made the public fully acquainted with the extent, capacities, and resources of that important, but till then little understood, acquisition of the British Crown. There is little doubt that it was the perusal of this valuable work which mainly decided Lord Melville to appoint Barrow, though then a perfect stranger to him, as his second secretary of the Admiralty. Barrow's subsequent career for forty years at the Admiralty (embracing the whole period of the war with France) will be for ever historically associated with the civil administration of the British navy for the same period. He enjoyed the esteem and confidence of all the eleven chief lords who successively presided at the Admiralty Board during that period, and more especially of King William IV., while lord high admiral, who honoured him with tokens of his personal regard. Barrow was a fellow of the Royal Society, and had the degree of LL.D. The honour of a baronetcy was conferred on him by Sir Robert Peel in 1835; the letter in which the honour was announced acknowledged, in highly gratifying terms, his literary and scientific eminence, and his "long, most able, and most faithful public service."

Besides the works already mentioned, Barrow published the lives of Lord Macartney, Lord Anson, Lord Howe, and Peter the Great; and he was also the author of several valuable contributions to the seventh edition of the *Encyclopædia Britannica.*

He retired from public life in 1845, in consideration of his advanced years, although still in vigorous possession of all the mental and bodily powers required for the due discharge of the functions of his office. In the course of the three following years his vital energies gradually declined, but he nevertheless continued so fully in the enjoyment of his faculties, writing a history of the modern Arctic voyages of discovery, of which he was a great promoter, as well as his autobiography, published in 1847, that his friends and relatives entertained no apprehension that his end was so near. He expired suddenly on the 23d November 1848, in the 85th year of his age, much honoured and respected by his friends and the public at large.

BARROWS. The custom of constructing barrows, or mounds of stones or earth, over the remains of the dead was the most characteristic feature of the sepulchral systems of primitive times. Originating in the common sentiment of humanity, which desires by some visible memorial to honour and perpetuate the memory of the dead, it was practised alike by nations of high and of low development, and continued through all the stages of culture that preceded the introduction of Christianity. The primary idea of sepulture appears to have been the provision of a habitation for the dead; and thus, in its perfect form, the barrow included a chamber or chambers where the tenant was surrounded with all the prized possessions of his previous life. A common feature of the earlier barrows is the enclosing fence, which marked off the site from the surrounding ground. When the barrow was of earth, this was usually effected by an encircling trench or a low *vallum.* When the barrow was a stone structure, the enclosure was usually a circle of standing stones. Sometimes, instead of a chamber formed above ground, the barrow covered a pit excavated under the original surface, in which the interments had been made. In later times the mound itself was frequently dispensed with, and the interments made under the natural surface, within the enclosure of a trench, a *vallum*, or a circle of standing stones. Usually the great barrows occupy conspicuous sites; but in general the external form is no index to the internal construction, and gives no absolute indication of the nature of the sepulchral usages. Thus, while the long barrow is characteristic of the Stone Age, it is impossible to tell without direct examination whether it may be chambered or unchambered, or whether the burials within it may be those of burnt or of unburnt bodies.

In England the long barrow usually contains a single chamber, entering by a passage underneath the higher and wider end of the mound. In Denmark the chambers are at irregular intervals along the body of the mound, and have no passages leading into them. The long barrows of Great Britain are often from 200 to 400 feet in length by 60 to 80 feet wide. Their chambers are rudely but strongly built, with dome-shaped roofs, formed by overlapping the successive courses of the upper part of the side walls. In Scandinavia, on the other hand, such dome-roofed chambers are unknown, and the construction of the chambers as a rule is megalithic, five or six monoliths supporting a capstone of enormous size. Such chambers denuded of the covering mound, or over which no covering mound has been raised, are popularly known in England as "cromlechs" and in France as "dolmens." The prevailing mode of sepulture in all the different varieties of these structures is by the deposit of the body in a contracted position, accompanied by weapons and implements of stone, occasionally by ornaments of gold, jet, or amber. Vessels of clay, more or less ornate in character, which occur with these early interments of unburnt bodies, are regarded as food vessels and drinking cups, differing in character and purpose from the cinerary urns of the Cremation Period in which the ashes of the dead were deposited.

The custom of burning the body commenced in the Stone Age before the long barrow or the cromlech, with their contracted burials, had passed out of use. While cremation is rare in the long barrows of the south of England, it is the rule in those of Yorkshire and the north of Scotland. In Ireland, where the long barrow form is all but unknown, the round barrow, or chambered cairn, prevailed from the earliest Pagan period till the introduction of Christianity. The Irish barrows occur in groups in certain localities, which seem to have been the royal cemeteries of the tribal confederacies, whereof eight are enumerated in an ancient Celtic manuscript on Pagan cemeteries. The best known of these was the burial-place of the kings of Tara. It is situated on the banks of the Boyne above Drogheda, and consists of a group of the largest cairns in Ireland. One of these, at New Grange, is a huge mound of stones and earth, over 300 feet in diameter at the base, and 70 feet in height. Around its base are the remains of a circle of large standing stones. The chamber, which is 20 feet high in the centre, is reached by a passage 70 feet in length. (See illustration, vol. ii. p. 384.)

As in the case of the long barrows, the traditional form

of the circular chambered barrows was retained through various changes in the sepulchral customs of the people, and we find it used both in connection with burnt and with unburnt burials. It was the natural result of the practice of cremation, however, that it should induce a modification of the barrow structure. The chamber, no longer regarded as a habitation to be tenanted by the deceased, became simply a cist for the reception of the urn which held his ashes. The degradation of the chamber naturally produced a corresponding degradation of the mound which covered it, and the barrows of the Bronze Age, in which cremation was the rule, are smaller and less imposing than those of the Stone Age, but often surprisingly rich in the relics of the life and of the art workmanship of the time. In addition to the varied and beautiful forms of implements and weapons,—frequently ornamented with a high degree of artistic taste,—armlets, coronets, or diadems of solid gold, and vases of elegant form and ornamentation in gold and bronze, are not uncommon. The barrows of the Bronze Period, like some of those of the Stone Age, appear to have been used as tribal or family cemeteries. In Denmark as many as seventy deposits of burnt interments have been observed in a single mound, indicating its use as a burying-place throughout a long succession of years.

In the early Iron Age there was a partial return to the more massive construction of the earlier periods. Sometimes chambers are found formed of timber instead of stones, in which the bodies were deposited unburnt, although the custom of cremation was largely continued. In Scandinavia both of these modes of sepulture lingered till the close of the Pagan time. One of the latest examples of the great timber-chambered barrow is that at Jellinge in Jutland, known as the barrow of Thyre Danebod, queen of King Gorm the Old, who died about the middle of the 10th century. It is a mound about 200 feet in diameter, and over 50 feet in height, containing a chamber 23 feet long, 8 feet wide, and 5 feet high, formed of massive slabs of oak. Though it had been entered and plundered in the Middle Ages, a few relics, overlooked by its original violators, were found when it was recently reopened, among which were a silver cup, ornamented with the interlacing work characteristic of the time, and some personal ornaments. It is highly illustrative of the tenacity with which the ancient sepulchral usages were retained even after the introduction of Christianity that King Harald, son and successor of Gorm the Old, who is said to have Christianized all Denmark and Norway, followed the Pagan custom of erecting a chambered tumulus over the remains of his father, on the summit of which was placed a rude pillar-stone, bearing on one side the memorial inscription in Runes, and on the other a representation of the Saviour of mankind distinguished by the crossed nimbus surrounding the head. The Kings' Hows at Upsala in Sweden rival those of Jellinge in size and height. In the chamber of one of them, which was opened in 1829, there was found an urn full of calcined bones; and along with it were some ornaments of gold showing the characteristic workmanship of the 5th and 6th centuries of the Christian era. Along with the calcined human bones were bones of animals, among which those of the horse and the dog were distinguished. In much earlier times the favourite horse or dog of the deceased was frequently deposited in Etruscan tombs, and the custom continued in Northern Europe until cremation, and the barbarous rights which usually accompanied it, were abolished by the stringent prohibitions of the Christian church.

Comparing the results of the researches in European barrows with such notices of barrow-burial as may be gleaned from early writings, we find them mutually illustrative.

The Homeric account of the building of the barrow of Hector (*Il.* xxiv.) brings vividly before us the scene so often suggested by the examination of the tumuli of prehistoric times. During nine days wood was collected and brought, in carts drawn by oxen, to the site of the funeral pyre. Then the pyre was built and the body laid upon it. After burning for twenty-four hours the smouldering embers were extinguished with libations of wine. The white and calcined bones were then picked out of the ashes by the friends and placed in a metallic urn, which was deposited in a hollow grave, or cist, and covered over with large well-fitting stones. Finally, a barrow of great magnitude was heaped over the remains, and the funeral feast was celebrated. The obsequies of Achilles, as described in the *Odyssey*, were also celebrated with details which are strikingly similar to those observed in tumuli both of the Bronze and Iron Ages. The body was brought to the pile in an embroidered robe, and jars of unguents and honey were placed beside it. Sheep and oxen were slaughtered at the pile. The incinerated bones were collected from the ashes and placed in a golden urn along with those of Patroclus, Achilles's dearest friend. Over the remains a great and shapely mound was raised on the high headland, so that it might be seen from afar by future generations of men.

Herodotus, describing the funeral customs of the Scythians, states that, on the death of a chief, the body was placed upon a couch in a chamber sunk in the earth and covered with timber, in which were deposited all things needful for the comfort of the deceased in the other world. One of his wives was strangled and laid beside him, his cup-bearer and other attendants, his charioteer, and his horses, were killed and placed in the tomb, which was then filled up with earth, and an enormous mound raised high over all. The barrows which cover the plains of ancient Scythia attest the truth of this description. A Siberian barrow, described by Demidoff, contained three contiguous chambers of unhewn stone. In the central chamber lay the skeleton of the ancient chief, with his sword, his spear, his bow, and a quiver full of arrows. The skeleton reclined upon a sheet of pure gold, extending the whole length of the body, which had been wrapped in a mantle broidered with gold and studded with precious stones. Over it was extended another sheet of pure gold. In a smaller chamber at the chief's head lay the skeleton of a female, richly attired, extended upon a sheet of pure gold, and similarly covered with a sheet of the same metal. A golden chain adorned her neck, and her arms were encircled with bracelets of pure gold. In a third chamber, at the chief's feet, lay the skeleton of his favourite horse with saddle, bridle, and stirrups.

So curiously alike in their general features were the sepulchral usages connected with barrow-burial over the whole of Europe, that we find the Anglo-Saxon Saga of Beowulf describing the chambered tumulus with its gigantic masonry "held fast on props with vaults of stone," and the passage under the mound haunted by a dragon, the guardian of the treasures of heathen gold which it contained. Beowulf's own burial is minutely described in terms which have a strong resemblance to the parallel passages in the *Iliad* and *Odyssey*. There is first the preparation of the pile, which is hung round with helmets, shields, and coats of mail. Then the corpse is brought and laid in the midst; the pile is kindled, and the roaring flame rises, mingled with weeping, till all is consumed. Then, for ten long days, the warriors labour at the rearing of his mighty mound on the headland, high and broad, to be seen afar by the passers by on land and sea.

The pyramids of Egypt, the mausolea of the Lydian kings, the sepulchres of the Atreidæ at Mycenæ, and the Etruscan tombs at Cære and Volci, are lineally descended

from the chambered barrows of prehistoric times, modified in construction according to the advancement of architectural art at the period of their erection. There is no country in Europe destitute of more or less abundant proofs of the almost universal prevalence of barrow-burial in early times. It can be traced on both sides of the basin of the Mediterranean, in Northern Africa, and in Asia Minor, across the plains of Mesopotamia, in the valley of Cabul, and throughout Western India. But more extended research in the archæology of these vast regions is needed to enable us to correlate their ancient remains with those of the European continent.

In the New World as well as in the Old, the same customs prevailed over vast areas from a very remote period. In the great plains of North America the dead were buried in barrows of enormous magnitude, which occasionally present a remarkable similarity to the long barrows of Great Britain. In these mounds cremation appears more frequently than inhumation; and both are accompanied by implements, weapons, and ornaments of stone and bone. The pottery accompanying the remains is often elaborately ornamented, and the mound builders were evidently possessed of a higher development of taste and skill than is evinced by any of the modern aboriginal races, by whom the mounds and their contents are regarded as utterly mysterious.

It is not to be wondered at that customs so widely spread and so deeply rooted as those connected with barrow-burial should have been difficult to eradicate. In fact, compliance with the Christian practice of inhumation in the cemeteries sanctioned by the church, was only enforced in Europe by capitularies denouncing the punishment of death on those who persisted in burying their dead after the Pagan fashion or in the Pagan mounds. Yet even in the Middle Ages kings were buried with their swords and spears, and queens with their spindles and ornaments; the bishop was laid in his grave with his crosier and comb, his chalice and vestments; and clay vessels filled with charcoal (answering to the urns of heathen times) are found with the interments in the churches of France and Denmark.

BARROW'S STRAITS, a portion of the channel which runs W. from Baffin's Bay through the islands of the Arctic archipelago to Melville Sound. It lies between 73° 45′ and 74° 40′ N. lat., is about 200 miles in length, and has an average breadth of 60 or 70 miles. In many places it is upwards of 200 fathoms in depth. The coasts on both sides are generally steep and rugged, with numerous bays and inlets, the most important of which is the Prince Regent Inlet, which runs S. into the Gulf of Boothia.

BARRY, SIR CHARLES, a distinguished English architect, was born at Westminster, May 23, 1795 After pursuing his elementary professional studies for six years as apprentice to a firm of architects at Lambeth, he set out, in 1817, on the customary foreign tour, visiting Greece and Italy, Egypt and Palestine, and enriching his memory and imagination by the study of the great buildings and remains of former ages. On his return to England in 1820 he settled in London, and was not slow in attaining distinction. One of the first works by which his abilities as an architect became generally known was the church of St Peter at Brighton,—an attempt in Perpendicular Gothic, completed in 1826. He built many other churches; but the marked preference for Italian architecture, which he acquired during his travels, showed itself in various important undertakings of his earlier years. In 1831 he erected the Travellers' Club in Pall Mall, a splendid work in the Italian style, and the first of its kind built in London. In the same style and on a grander scale, he erected, some years later, the Reform Club. It is unnecessary to particularize the numerous private mansions on which he was engaged, one of the latest and most magnificent of which was Bridgewater House, the town residence of the earl of Ellesmere. Birmingham possesses one of his best works in the buildings of King Edward's grammar school, in the Tudor style. For Manchester he designed the Athenæum, in the Italian style; and for Halifax, the town-hall. He was engaged for some years in reconstructing the Treasury buildings, Whitehall. But his masterpiece, and perhaps, notwithstanding all unfavourable criticism, the masterpiece of English architecture of the 19th century, is the new palace at Westminster. After the destruction of the old houses of parliament by fire in October 1834, Barry was the successful competitor for erecting the new palace. The first stone was laid in the spring of 1840; the work was steadily carried on in the face of many difficulties, and through a maze of private dissensions and public complaints, and it was at length completed in 1860. Twenty years seemed long in passing, but once past the time assuredly will no more seem too long to have been employed in the erection, or, we might say, allowed for the growth of this stately and beautiful pile, one of the truest glories of the banks of the Thames. Barry was elected A.R.A. in 1840, and R.A. in the following year. His genius and achievements were recognized by the representative artistic bodies of the principal European nations; and his name was enrolled as a member of the academies of art at Rome, Berlin, St Petersburg, Brussels, and Stockholm. He was chosen F.R.S. in 1849, and was knighted by the Queen in 1852. He died suddenly at Clapham, near London, May 12, 1860, and his remains were interred in Westminster Abbey. In 1867 appeared a life of Sir Charles Barry by his son, Dr Alfred Barry, principal of King's College, London. A claim was thereupon set up on behalf of Mr A. Welby Pugin deceased, who had been Barry's assistant, to a much larger share in the work of designing the Westminster Palace than was admitted in Dr Barry's narrative. The controversy raged for a time, but without substantiating Mr Pugin's claim.

BARRY, JAMES, an eminent painter, was born at Cork on the 11th October 1741. His father had been a builder, and, at one time of his life, a coasting trader between the two countries of England and Ireland. To this business of trader James was destined, and he actually made, when a boy, several voyages; but these being forced upon him, he on one occasion ran away from the ship, and on all others manifested such an aversion to the life and habits of a sailor, as to induce his father to relinquish all hopes of him in this line, and to suffer him to pursue his inclinations, which led strongly towards drawing and study. At the schools in Cork to which he was sent, he was distinguished above his school-fellows by his talents and industry; his habits differed from those of ordinary boys; he seldom mixed in their games or amusements, but during play-hours stole off to his own room, where he worked at his pencil, or studied some book that he had borrowed or bought. As his industry was excessive, his advances in the acquisition of knowledge were rapid, and he was regarded as a prodigy by his school-fellows. About the age of seventeen he first attempted oil painting, and between that and the age of twenty-two, when he first went to Dublin, he produced several large pictures, which decorated his father's house,

and represented subjects not often chosen by young artists, such as Æneas escaping with his family from the flames of Troy, Susanna and the elders, Daniel in the lions' den, &c. At this period he also produced the painting which first brought him into public notice, and gained him the acquaintance and patronage of Edmund Burke. The picture was founded on an old tradition of the landing of St Patrick on the sea-coast of Cashel, and of the conversion and baptism of the king of that district by the patron saint of Ireland. Barry's manner of treating it was such as to gain for him the applause and admiration of the connoisseurs of London, where it was exhibited in 1762 or 1763.

By the liberality of Burke and his other friends, Barry, in the latter part of 1765, was enabled to proceed to the Continent, where he remained till the beginning of 1771, studying his art with an enthusiasm which seemed to augur the highest success, and making observations on the different *chefs d'œuvre* of Italy with equal independence of judgment and nicety of discrimination. He proceeded first to Paris, then to Rome, where he remained upwards of three years, from Rome to Florence and Bologna, and thence home through Venice. His letters to the Burkes, giving an account of Michel Angelo, Raffaelle, Titian, and Leonardo da Vinci, show a complete insight into the characteristic merits of their works, and would make us wonder (if the case were at all singular) how he could enter with such force, delicacy, and feeling, into excellences of which he transplanted nothing into his own works.

Even in copying from the antique he manifested the same aversion to labour, or to that kind of labour which, by showing us our defects, compels us to make exertions to remedy them. He made all his drawings from the antique by means of a *delineator*, that is, a mechanical instrument, to save the trouble of acquiring a knowledge both of form and proportion. Barry painted two pictures while abroad, his Adam and Eve, and his Philoctetes. The first of these he sent home as a specimen of his progress in the art. It does not appear to have given much satisfaction. His Philoctetes he brought home with him. It is a coarse, unclassical performance,—the direct opposite, indeed, of all that he thought it to be. Soon after his return to England he produced his picture of Venus, which has been compared, though with little justice, to the Galatea of Raffaelle, the Venus of Titian, and the Venus de Medici. In 1773 he exhibited his Jupiter and Juno on Mount Ida, which was much praised by some critics of that day. His Death of General Wolfe, in which the British and French soldiers are represented in very primitive costumes, was considered as a falling off from his great style of art, the painting of Greek subjects, and, accordingly, it is said to "have obtained no praise." His fondness for Greek costume was assigned by his admirers as the cause of his reluctance to paint portraits,—as if the coat were of more importance than the face. His fastidiousness in this respect, and his frequent excuses or blunt refusals to go on with a portrait of Burke which he had begun, caused a misunderstanding with his early patron, which does not appear to have been ever entirely made up. The difference between them is said to have been widened by Burke's growing intimacy with Sir Joshua Reynolds, and by Barry's feeling some little jealousy of the fame and fortune of his rival "in a humbler walk of the art." About the same time he painted a pair of classical subjects, Mercury inventing the lyre, and Narcissus looking at himself in the water, the last suggested to him by Burke. He also painted an historical picture of Chiron and Achilles, and another of the story of Stratonice, for which last the duke of Richmond gave him a hundred guineas. In 1773 it was proposed to decorate the interior of St Paul's with historical and sacred subjects; but the plan fell to the ground, from not meeting with the concurrence of the bishop of London and the archbishop of Canterbury. Barry was much mortified at the failure, for he had in anticipation fixed upon the subject he intended to paint,—the rejection of Christ by the Jews when Pilate proposes his release. In 1773 he published *An Inquiry into the real and imaginary Obstructions to the Acquisition of the Arts in England*, vindicating the capacity of the English for the fine arts, and tracing their slow progress hitherto to the Reformation, to political and civil dissensions, and, lastly, to the general direction of the public mind to mechanics, manufactures, and commerce. In the year 1774 a proposal was made, through Mr Valentine Green, to Reynolds, West, Cipriani, Barry, and other artists, to ornament the great room of the Society for the Encouragement of Arts, Manufactures, and Commerce, in the Adelphi, with historical and allegorical paintings. This proposal was at the time rejected by the artists themselves; but, in 1777, Barry made an offer to paint the whole on condition of being allowed the choice of his subjects, and being paid by the society the expenses of canvas, paints, and models. His offer was accepted, and he finished the series of pictures at the end of seven years, instead of two, as he had proposed to himself, accomplishing his task to the entire satisfaction of the members of the society, who granted him two exhibitions, and at different periods voted him 50 guineas, their gold medal, and 200 guineas. Of the six paintings making up the series, only one, that of the Olympic Games, shows any artistic power.

Soon after his return from the Continent Barry had been chosen a member of the Royal Academy; and in 1782 he was appointed professor of painting, in the room of Mr. Penny, with a salary of £30 a year. The lectures which he delivered from the chair were full of strong sense and wholesome advice, both to the students and academicians. Among other things, he insisted much on the necessity of purchasing a collection of pictures by the best masters as models for the students, and proposed several of those in the Orleans collection. This recommendation was not relished by the academicians, and quarrels arose, which reached such a height, that, in 1799, Barry was expelled from the academy, soon after the appearance of his *Letter to the Dilettanti Society*, a very amusing but eccentric publication, full of enthusiasm for his art and at the same time of contempt for the living professors of it. After the loss of his salary, a subscription was set on foot by the earl of Buchan to relieve him from his difficulties, and to settle him in a larger house to finish his picture of Pandora. The subscription amounted to £1000, with which an annuity was bought, but of this he was prevented from enjoying the benefit, for, on the 6th of February 1806, he was seized with a pleuritic fever, and died on the 22d of the same month. On the 14th of March his remains were interred in the cathedral of St Paul's.

As an artist, Barry is more distinguished for the strength of his conceptions, and for his resolute and persistent determination to apply himself only to great subjects, than for his skill in designing or for beauty in his colouring. His ideas were generally fine, but the realization of them was almost without exception unsuccessful. His drawing is rarely good, his colouring frequently wretched. This curious contradiction in his artistic powers was in complete harmony with his general character. He was extremely impulsive and unequal; sometimes morose, sometimes sociable and urbane; jealous of his contemporaries, and yet capable of pronouncing a splendid eulogy on Reynolds.

BARS, a county of Hungary, in the district watered by the Neutra, Gran, and Zsitva, which belong to the northern part of the system of the Danube. It is for the most part mountainous and has great mineral wealth,

especially in gold and silver. The most remarkable mines are those of Skleno and Vihnye. The chief towns are Kremnitz or Körmöcz Bánya, and Neusohl or Beszterczc-Bánya. Population in 1869, 137,191, mostly Roman Catholics.

BARTAN, a town in Asiatic Turkey, situated near the mouth of the Bartan-su, which was known to the Greeks as the *Parthenius*, and formed part of the boundary between Bithynia and Paphlagonia. The town is built on two low limestone hills, and has its streets paved with blocks of that material. It carries on a considerable trade with Constantinople, which might be increased were it not for the obstruction of the harbour by a bar. Population between six and seven thousand.

BARTAS, GUILLAUME DE SALLUSTE DU, a French poet, was born in 1544, and died in 1590 of wounds received in the battle of Ivry. He was employed by Henry IV. of France in England, Denmark, and Scotland; and he commanded a troop of horse in Gascony, under the Marshal de Martingan. His principal work, *La Sepmaine*, a poem on the creation of the world, which has long since fallen into oblivion, once enjoyed a high reputation, thirty editions of it having been printed within six years after its appearance. Its religious tone and rather fanciful style made it a great favourite with English writers of the time, by whom the author was always designated as the divine Du Bartas, and placed on an equality with Ariosto. Spenser, Hall, and Ben Jonson, all speak in the highest terms of what seems to us a most uninteresting poem. King James VI. tried his "prentice hand" at the translation of Du Bartas's poem *L'Uranie*, and the compliment was returned by the French writer translating, as *La Lepanthe*, the monarch's poem on the battle of Lepanto. Joshua Sylvester, one of the Spenserian poets, translated the *Sepmaine* in 1598, and the work in its English form was extremely popular and exercised no slight influence on English literature. Du Bartas published a second *Week* in 1584; portions of it and of the first were translated by Th. Hudson, William Lisle, and Thomas Winter.

BARTFELD, or BARTFA, a town of Hungary, county of Saros, on the River Tepla. It has some trade in wine, corn, linen and woollen goods, paper, &c., and is noted for the mineral springs in the vicinity, the water of which is largely exported. Its Gothic church is adorned with numerous artistic treasures, and its archives are rich in ancient documents. Population, 5303.

BARTH, HEINRICH, a distinguished African explorer, was born at Hamburg, February 16, 1821. At the age of eighteen he went to Berlin, and completed his education at the university of that city. After a year of study he set out to travel in Italy and Sicily, returning to Berlin in 1841, and continuing his studies for three years. He took his degree in 1844, and yielding to a desire, which had long possessed him, to explore the countries lying on the Mediterranean, he made his first visit to North Africa in 1845. Before setting out he had visited London and Paris, and made himself acquainted with the Arabic language. He reached Tunis, Tripolis, Benghasi, explored Cyrenaica, and travelled down the valley of the Nile. On his return journey he was attacked and wounded by robbers. In 1847 he travelled in Egypt and Palestine, and in Asia Minor and the islands off its coasts, and from Constantinople returned through Greece to Berlin. For a time he was engaged there as *Privat-docent*, and in preparing for publication the narrative of his *Wanderungen durch die Küstenländer des Mittelmeeres*, which appeared in 1849. At the suggestion of Bunsen and Ritter he entered with enthusiasm into the project of the English expedition for the exploration of Central Africa, and set out with Overweg in November 1849. Five years were devoted to their explorations, and Barth did not arrive in Europe till September 1855. His account, entitled *Reise und Entdeckungen in Nord- und Centralafrika*, appeared in 5 vols., between 1855 and 1858, and was followed by a collection of Central African vocabularies (1862–64). Dr Barth had not yet exhausted his energies as a traveller. In 1858 he undertook another journey in Asia Minor, and in 1862 visited Turkey in Europe. In the following year, having returned to Berlin, he was appointed professor of geography at the university, and president of the Geographical Society. He died at Berlin, November 25, 1865.

BARTH, or BART, JEAN, son of a fisherman of Dunkirk, was born in 1651 and died in 1702. He served, when young, in the Dutch navy, but when war broke out between Louis XIV. and Holland, he entered the French service. He gained great distinction in the Mediterranean, where he held an irregular sort of commission, not being then able from his low birth to receive a command in the navy. His success was so great, however, that he was made a lieutenant. He rose rapidly to the rank of captain, and then to that of admiral. The peace of Ryswick put a close to his active service. Many anecdotes are narrated of the courage and bluntness of the uncultivated sailor, who became the popular hero of the French naval service. (Richer, *Vie de Jean Bart*, 1780, and many editions since; Vanderest, *Histoire de Jean Bart.*)

BARTHÉLEMY, AUGUSTE MARSEILLE, a French satirical poet, was born at Marseilles in 1796, and died in 1867. After having established some local reputation as a poet he went to Paris, where by one of his first efforts, *Le Sacre de Charles X.*, 1825, he gained the favour of the court. His energies, however, were soon enlisted in the service of the opposition party. In 1826 appeared the clever political satire, *Le Villèliade*, a mock heroic poem, the joint production of Barthélemy and his constant friend Méry, also a native of Marseilles. The success was immediate and pronounced; fifteen editions were called for during the year, and the authors cleared nearly £1000. A rapid succession of political squibs and satires was now poured forth by the authors, one of the most remarkable being *Napoléon en Égypte*, 1828, which passed through nearly a dozen editions in a year. In 1829 Barthélemy had become so offensive to the Government that he was imprisoned and fined 1000 francs. The Revolution of 1830 liberated him; and in company with Méry, he celebrated the triumph of the people in one of their most brilliant efforts, *L'Insurrection*. During the next two years Barthélemy, though enjoying for a time a pension from Louis Philippe, did not cease his attacks on the Government and its ministers. In 1832, however, he made a curious change, the motive for which is not clear, but the effect of which was seriously to impair, almost to destroy his influence. In that year he published an anonymous poem, supporting some acts of the Government which were peculiarly obnoxious to the Liberal party, and, on the work being attacked, defended it openly. For the next few years he enjoyed a handsome pension from the Government, and refrained from all satirical writing. He again resumed his old style in 1844, but without the former success. From that date he contented himself with merely occasional poems.

BARTHÉLEMY, JEAN JACQUES, a celebrated French writer, was born on the 20th January 1716, at Cassis, a little seaport on the shores of the Mediterranean. He was educated, first at the college of the Oratory in Marseilles, and afterwards at that of the Jesuits in the same city. While completing the course of study requisite for the church, which he intended to join, he devoted much attention to Oriental languages, in which he became very proficient. After assuming the ecclesiastical habit, he

resided with his family at Aubagne, and during this period of his life was introduced by his friend, M. Cary of Marseilles, to the study of classical antiquities, particularly in the department of numismatics. In 1744 he repaired to Paris, carrying with him a letter of introduction to M. Gros de Boze, perpetual secretary of the Academy of Inscriptions and Belles Letters, and keeper of the medals. He became assistant to De Boze, and on the death of the latter in 1753, was appointed his successor. In the following year he was enabled to pay a visit to Italy, and spent some time in that country, inspecting its rich treasures of classical remains. While on his journey he made the acquaintance of the French ambassador, M. de Stainville, afterwards duc de Choiseul, and of his wife. The minister conceived a great regard for Barthélemy, and on his accession to power loaded the scholar with benefits. In 1759 he gave him a pension on the archbishopric of Albi; in 1765 he conferred on him the treasurership of St Martin de Tours, and, in 1768, made him secretary-general to the Swiss guards. In addition to these sources of revenue, the abbé enjoyed a pension of 5000 livres on the *Mercure de France*. His income, which was thus considerable, was well employed by him; he supported and established in life three nephews, and gave largely to indigent men of letters. In 1789, after the publication of his great work, he was elected a member of the French Academy, one of the highest honours to which a French author aspires. During the troubled years of the Revolution, Barthélemy, from his position and habits, took no share in any public affairs. Yet he was informed against and arrested as an aristocrat. So great, however, was the respect felt for his character and talents, that the Committee of Public Safety were no sooner informed of the arrest, than they gave orders for his immediate release. Barthélemy died soon after, on the 30th April 1795.

The great work on which Barthélemy's fame rests appeared in 1788, and was entitled *Voyage du jeune Anacharsis en Grece, dans le milieu du quatrième siècle avant l'ere Chrétienne.* He had begun it in 1757, and, during an uninterrupted succession of thirty years, occupied his leisure hours in bringing it to maturity. The hero, a young Scythian, descended from the famous philosopher Anacharsis, whose name be bears, is supposed to repair to Greece for instruction in his early youth, and after making the tour of her republics, colonies, and islands, to return to his native country and write this book in his old age, after the Macedonian hero had overturned the Persian empire. In the manner of modern travellers, he gives an account of the customs, government, and antiquities of the country he is supposed to have visited; a copious introduction supplies whatever may be wanting in respect to historical details; whilst various dissertations on the music of the Greeks, on the literature of the Athenians, and on the economy, pursuits, ruling passions, manners, and customs, of the surrounding states, supply ample information on the subjects of which they treat. The author, indeed, is not profound; and the young Scythian seldom penetrates much below the surface. But his remarks are commonly judicious, and to considerable erudition he unites singular skill in the distribution of his materials, and a happy talent for presenting his subject in the most agreeable and attractive form. The assumed character is so admirably sustained throughout, that we can scarcely persuade ourselves we are not perusing a book of real travels, and communing with an actual personage who has recorded his observations and experience for the instruction and improvement of his countrymen. Modern scholarship has superseded most of the details in the *Voyage*, but the author himself did not imagine his book to be a register of accurately ascertained facts; he rather intended to afford to his countrymen, in an interesting form, some knowledge of Greek civilization. The *Charicles* of Becker is a more recent attempt in a similar direction, but, though superior in scholarship, it wants the charm of style which is the principal quality in the *Anacharsis*.

BARTHEZ, or BARTHÈS, PAUL JOSEPH, one of the most celebrated physicians of France, was born on the 11th of December 1734, at Montpellier. He received his early education at Narbonne and Toulouse, and soon gave decisive indications of the great talents with which nature had endowed him. He commenced the study of medicine at Montpellier in 1750, and in 1753, when he had only attained his nineteenth year, he received his doctor's degree. He afterwards occasionally visited Paris, where he attracted the notice and acquired the friendship of the most distinguished literati of the period. In 1756 he obtained the appointment of physician to the military hospital in Normandy attached to the army of observation commanded by Marshal d'Estrées. A severe attack of hospital fever compelled him to leave this post; but the numerous cases which had come under his notice furnished materials for several papers contributed to the *Memoirs of the Academy of Sciences*. In 1757 his services were required in the medical staff of the army of Westphalia, where he had the rank of consulting physician. After his return to Paris he acted for some time as joint editor of the *Journal des Savans* and the *Encyclopédie Méthodique.* In 1761 he obtained a medical professorship at Montpellier, in which his abilities as a teacher soon shone forth with unrivalled lustre. His success was the more honourable, inasmuch as his colleagues—Lamure, Leroy, and Venel—were men of distinguished reputation, and had raised the school to a high pitch of celebrity.

In 1774 he was created joint chancellor of the university, with the certainty of succeeding singly to the office on the death of the colleague, which happened in 1786. He afterwards took the degree of doctor in civil law, and was appointed counsellor to the Supreme Court of Aids at Montpellier. In 1780 he was induced to fix his residence in Paris, having been nominated consulting physician to the king, with a brevet of counsellor of state, and a pension of a hundred louis. Honours were now heaped upon him; he was admitted free associate to the Academies of Sciences and of Inscriptions, and appointed first physician to the duke of Orleans, in the room of Tronchin. His reputation increased in proportion as his merits were displayed on a wider theatre. He practised as a physician at Paris for nearly ten years, and received the most flattering testimonials of public approbation.

The outbreak of the French Revolution compelled Barthez to leave Paris. He lost considerable part of his fortune, and retired to Carcassonne, where he devoted himself to the study of theoretical medicine. It was in this retreat that he gave to the world his *Nouvelle Mécanique des Mouvemens de l'Homme et des Animaux*, which appeared in 1798.

On the re-establishment of the College of Medicine at Montpellier, Barthez was naturally looked upon as the person most likely to revive its former fame. But age and infirmity operated to dissuade him from resuming the laborious office of teacher, and he was accordingly nominated honorary professor. In 1802 he received several marks of favour from the new government under Bonaparte; he was nominated titular physician to the Government, and afterwards consulting physician to the emperor, and member of the Legion of Honour.

His *Traitement des Maladies Goutteuses*, in two vols. 8vo, appeared in 1802, and he afterwards occupied himself in preparing for the press a new edition of his *Élémens de la Science de l'Homme*, of which he just lived to see the publication. His health had been declining for some years before his death, which took place soon after his removal to Paris, on the 15th of October 1806, in the 72d year of his age. He bequeathed his books and manuscripts to M. Lordat, who, in consequence, published two volumes of *Consultations de Médicine*, Paris, 1810, 8vo, to which he prefixed a preface of his own. Another posthumous work of Barthez, the *Traité du Beau*, preceded by some account of his life, was edited in 1807 by his brother, M. Barthez de Marmorières.

Barthez has enjoyed a much higher reputation on the Continent than in England, where, indeed, his writings

are comparatively little known. His principal work is the *Nouveaux Élémens de la Science de l'Homme*, in which he unfolds his doctrine of the vital principle, or formative force. He was one of the strongest opponents of the theory which would explain the phenomena of life by physical or chemical laws. (See Lordat, *Exposition de la doctrine médicale de P. J. Barthez*, 1818.)

BARTHOLINUS, GASPARD, a learned Swede, born in 1585, at Malmoë. His precocity was extraordinary; at three years of age he was able to read, and in his thirteenth year he composed Greek and Latin orations, and delivered them in public. When he was about eighteen he went to the University of Copenhagen, and he afterwards studied at Rostock and Wittemberg. He then travelled through Germany, the Netherlands, England, France, and Italy, and was received with marked respect at the different universities he visited. In 1613 he was chosen professor of medicine in the University of Copenhagen, and filled that office for eleven years, when, falling into a dangerous illness, he made a vow, that if it should please God to restore him, he would apply himself solely to the study of divinity. He recovered, observed his vow, and soon after obtained the professorship of divinity, with the canonry of Rotschild. He died on the 13th of July 1630, after having written nearly fifty works on different subjects.

BARTHOLINUS, THOMAS, a physician, son of the above, was born at Copenhagen in 1619. He studied medicine at Leyden for three years (1637–40). He then travelled into France, and resided two years at Paris and Montpellier, in order to improve himself under the distinguished physicians of those universities; after which he visited Italy, remained three years at Padua, and then went to Basel, where he obtained the degree of doctor in philosophy. Returning to Copenhagen, he was appointed professor of mathematics in 1647, and next year was nominated to the chair of anatomy, for which he was better qualified. This he held for thirteen years, distinguishing himself by several observations respecting the lacteal and lymphatic vessels, shortly after their discovery by Olaus Rudbeck. His close application, however, having affected his health, he resigned his chair in 1661, and retired to a little estate at Hagestaed, near Copenhagen, where he hoped to spend the remainder of his days in peace; but his house having been burnt in 1670, his library, with all his books and manuscripts, was consumed. In consideration of this loss the king appointed Bartholinus his physician, with a handsome salary, and exempted his land from all taxes; the University of Copenhagen also chose him for their librarian; and, in 1675, he was honoured with a seat in the grand council of Denmark. He died on the 4th of December 1680. He wrote *Anatomia Gaspardi Bartholini Parentis, novis Observationibus primum locupletata*, 8vo; *De Monstris in Natura et Medicina*, 4to; *Schedion de Armillis Veterum, præsertim Danorum*, 8vo; and several other works.

BARTHOLOMEW, ST (בַּר תַּלְמַי, son of Talmai), one of the twelve apostles, generally supposed to have been the same as Nathanael (John i. 45). He was a native of Cana in Galilee (John xxi. 2), and was introduced by Philip to Jesus, who, on seeing him approach, at once pronounced that eulogy on his character which has made the name Nathanael almost synonymous with sincerity. He was a witness of the resurrection and the ascension, and returned with the other apostles to Jerusalem. Of his subsequent history we have little more than vague traditions. According to Eusebius (*Hist. Eccles.*, v. 10), when Pantænus went on a mission to the Indians (towards the close of the 2d century), he found among them the Gospel of Matthew, written in Hebrew, which had been left there by the apostle Bartholomew. Jerome (*De Vir. Illustr.*, c. 36) gives a similar account. But the name Indians is applied by ancient writers to so many different nations, that it is difficult to determine the scene of Bartholomew's labours. Mosheim (with whom Neander agrees) is of opinion that it was a part of Arabia Felix, inhabited by Jews, to whom alone a Hebrew gospel could be of any service. According to the received tradition, this apostle was flayed alive and crucified with his head downwards, at Albanopolis in Armenia, or, according to Nicephorus, at Urbanopolis in Cilicia. A spurious gospel which bears his name is in the catalogue of apocryphal books condemned by Pope Gelasius. The festival of St Bartholomew is celebrated on the 24th of August.

BARTOLINI, LORENZO, an Italian sculptor, was born in 1777, of very humble parents, at Vernio in Tuscany. After various vicissitudes in his youth, during which he had acquired great skill and reputation as a modeller in alabaster, he came to Paris in 1797. He there studied painting under Desmarets, and afterwards sculpture under Lemot. The bas-relief Cleobis and Biton, with which he gained the second prize of the Academy in 1803, at once established his fame as a sculptor of first-rate ability, and gained for him a number of influential patrons. He executed many minor pieces for Denon, besides busts of Méhul and Cherubini. His great patron, however, was Napoleon, for whom he executed a colossal bust, and who sent him to Carrara to found a school of sculpture. He remained in Carrara till after the fall of Napoleon, and then took up his residence in Florence, where he continued to reside till his death in 1850. His works, which include an immense number of busts, are numerous and varied. The best are, perhaps, the group of Charity, the Hercules and Lichas, and the Faith in God, which exemplify the highest types of Bartolini's style. By the Italians he is ranked next to Thorwaldsen and Canova.

BARTOLOZZI, FRANCESCO, a distinguished engraver, was born at Florence in 1725, or according to some authorities, in 1730. He was originally destined to follow out the profession of his father, who was a silversmith; but he manifested so much skill and taste in designing that he was placed under the superintendence of two Florentine artists, who instructed him in painting. After devoting three years to that art, he went to Venice and studied engraving under the famous Joseph Wagner. He made very rapid progress, and executed some works of considerable importance at Venice. He then removed for a short time to Rome, where he completed a set of engravings representing events from the life of St Nilus, and after returning to Venice, set out for London in 1764. For nearly forty years he resided in London, and produced an enormous number of engravings, the best being those of Clytie, after Annibale Carracci, and of the Virgin and Child, after Carlo Dolce. A great proportion of them are from the works of Cipriani and Angelica Kauffmann. Bartolozzi also contributed a number of plates to Boydell's *Shakespeare Gallery*. In 1802 he was invited to Lisbon to superintend a school of engraving in that city. He remained in Portugal till his death, at an advanced age, about the year 1816.

BARTOLUS, professor of the civil law at the University of Perugia, and the most famous master of the dialectical school of jurists, was born in 1314, at Sasso Ferrato, in the duchy of Urbino, and hence is generally styled Bartolus de Saxo Ferrato. His father was Franciscus Severi, and his mother was of the family of the Alfani. He studied the civil law first of all under Cinus at Perugia, and afterwards under Oldradus and Jacobus de Belvisio at Bologna, where he was promoted to the degree of doctor of civil law in 1334. His great reputation dates from his appointment to a chair of civil

law in the University of Perugia, 1343, where he lectured for many years, raising the character of the law school of Perugia to a level with that of Bologna. He died in 1357 at Perugia, where a magnificent monument recorded the interment of his remains in the church of San Francisco, by the simple inscription of "Ossa Bartoli." Bartolus has left behind him a great reputation, and many writers have sought to explain the fact by attributing to him the introduction of the dialectical method of teaching law; but the dialectical method had been employed by Odofredus, a pupil of Accursius, in the previous century, and the successors of Odofredus had abused it to an extent which has rendered their writings in many instances unprofitable to read, from the subject matter being overlaid with dialectical forms. It was the merit of Bartolus, on the other hand, that he employed the dialectical method with advantage as a teacher, and discountenanced the abuse of it; but his great reputation is more probably owing to the circumstance that he revived the exegetical system of teaching law (which had been neglected since the ascendency of Accursius), in a spirit which gave it new life, whilst he was enabled to impart to his teaching a practical interest, from the judicial experience which he had acquired whilst acting as assessor to the courts at Todi and at Pisa before he undertook the duties of a professorial chair. His treatises *On Procedure* and *On Evidence* are amongst his most valuable works, whilst his *Commentary on the Code of Justinian* has been in some countries regarded as of equal authority with the code itself.

BARTON, Benjamin Smith, M.D., an American naturalist, who was the first professor of botany and natural history in a college in the United States. He was born in Pennsylvania in 1766, studied for two years at Edinburgh, and afterwards graduated at Göttingen. He settled at Philadelphia, and soon obtained a considerable practice. In 1789 he was appointed to the professorship above mentioned in Philadelphia College; he was made professor of materia medica in 1795, and on the death of Dr Rush in 1813 he obtained the chair of practical medicine. In 1802 he was chosen president of the American philosophical Society. Barton was the author of various works on natural history, botany, and materia medica. By his lectures and writings he may be said to have founded the American school of natural history. He died in 1815.

BARTON, Elizabeth, the "Maid of Kent," belonged to the village of Aldington in Kent. She was a pious, nervous, and enthusiastic person, subject to epilepsy; and her enthusiasm, unfortunately for herself, took a political turn at a somewhat critical period in English history. When all England was excited with the attempts made by Henry VIII. to obtain a divorce from Queen Catherine, Elizabeth Barton saw visions and heard speeches, all of which related to the contemplated divorce. These she confided to her parish priest, Richard Masters, and he made them known to Dr Bockling, a canon of Canterbury. Through these men they became widely known, and were everywhere proclaimed to be divine revelations. The chapel at Aldington became the centre of many pilgrimages, and the scene of many excited and tumultuous assemblies. Elizabeth Barton was commonly believed to be a prophetess, and was called the "holy maid of Kent." Meanwhile her visions continued; she saw letters written in characters of gold sent to her by Mary Magdalene, which contained both revelations and exhortations. Among other things she declared that it was revealed to her that if the contemplated divorce took place, the king would be a dead man within seven months. The principal agents for the Pope and for Queen Catherine lent themselves to fan the excitement. Even such men as bishops Fisher and Warham and Sir Thomas More corresponded with the Maid of Kent. At last the king's wrath was aroused. In 1533 Elizabeth with her principal supporters, Masters, Bockling, and several others, were examined before parliament, and sentenced to be executed. She was beheaded at Tyburn, April 21, 1534. (*Cf.* Burnet's *History of the Reformation in England;* Lingard's *History of England.*)

BARUCH, son of Neriah, was the friend and amanuensis of the prophet Jeremiah. After the temple at Jerusalem had been plundered by Nebuchadnezzar, he wrote down Jeremiah's prophecies respecting the return of the Babylonians to destroy the state, and read them in the temple before the assembled people at the risk of his life. The roll having been burned by the king's command, Jeremiah dictated the same again. When the temple was destroyed, Baruch went to Egypt with Jeremiah, having been blamed as the prompter of the threatening prophecies uttered by the latter. Nothing certain is known as to his death,—some accounts representing him as dying in Egypt, others in Babylonia. The Talmud adopts the latter opinion, making him the instructor of Ezra, to whom he is said to have communicated the traditions he had received from Jeremiah.

The Book of Baruch belongs to the Apocrypha, according to Protestants, and to the deutero-canonical productions, according to Roman Catholics.

There is hardly sufficient cause for dividing the book, as some critics suggest, between two writers. The author of iii. 9–v. 9 uses Isaiah as well as Jeremiah in two places. A new paragraph undoubtedly begins at iii. 9, which has little connection with the preceding context, and differs from it perceptibly both in matter and form; yet it has the same general object. From reproof the language passes to hope and Messianic happiness, and it becomes livelier and more elevated. It is purer Greek without doubt. The supposed traces of Alexandrian culture are somewhat indistinct. Wisdom is not spoken of in the Alexandrian manner (iii. 24), but rather in the same way as in Sirach, which is Palestinian.

Much difference of opinion prevails regarding the original language. Some are for a Greek original, others for a Hebrew one; while Fritzsche and Ruetschi think that the first part was composed in Hebrew, the second in Greek. The original seems to have been Hebrew, though Jerome says that the Jews had not the book in that language; and Epiphanius asserts the same thing. The testimony of the former resolves itself into the fact that the original had been supplanted by the Greek; and that of the latter is not of much value, since he gives Baruch, along with Jeremiah and the Lamentations, in a second list of the canonical books.[1] We rely on the statement that the work was meant to be publicly read in the temple (i. 14) as favourable to a Hebrew original, as well as on the number and nature of the Hebraisms, which are sometimes so peculiar that they cannot be resolved into the authorship of a Greek-speaking Jew. That the writer was a Palestinian appears from various passages, such as ii. 17, "For the dead that are in the graves, whose souls are taken from their bodies, will give unto the Lord neither praise nor righteousness;" "Hearken, O ye that dwell about Zion" (iv. 9); "Ye have forgotten the everlasting God that brought you up; and ye have grieved Jerusalem that nursed you" (iv. 8). Both the latter passages betray a Palestinian. Besides, the conception of Wisdom in iii. 12, &c., is Palestinian rather than Alexandrian; for the words in iii. 37 do not refer to the incarnation of the Logos, but to personified Wisdom, as in Sirach xxiv. 10. This points to a Hebrew original. The version seems to be free, especially in the latter part.

[1] *Hæres.*, viii. 6; compare *De Mens. et Pond.*, c. 23; *ibid.*, c. 5.

Who was the translator? A comparison of the Septuagint translation of Jeremiah with that of Baruch will suggest the answer. The agreement between the two is remarkable. Constructions, phrases, and words are the same in them, so that we may conjecture with Ewald and Hitzig that the same translator appears. The words βαδίζω, ἀποστολή, χαρμοσύνη, γαυρίαμα, δεσμώτης, ἀποικισμός, ὄνομα μου ἐπικαλεῖσθαι ἐπί τινι are common to both. The LXX. version of Jeremiah was not made till the 1st century B.C. or later; and Theodotion's translation or recension of it in the second. It is some confirmation of the opinion that Greek was not the original when marginal notes are found in the Hexaplar-Syriac version printed by Ceriani, in which the Hebrew is repeatedly referred to. Nothing seems to disprove the assumption that Theodotion, from whose version that of Paul of Tela was taken, had the Hebrew original before him.

Though Baruch professes to have written the book, a later writer speaks in his name. Jeremiah's faithful friend is said to have composed it at Babylon. This view is untenable on the following grounds:—

1. The work contains historical inaccuracies. Jeremiah was living in the fifth year after the destruction of Jerusalem, yet the epistle is dated that year at Babylon. It is unlikely that Baruch left Jeremiah, since the two friends were so united. According to Baruch i. 3, Jeconiah was present in the great assembly before which the epistle was read, whereas we learn from 2 Kings xxv. 27 that he was kept a prisoner as long as Nebuchadnezzar lived. Joakim is supposed to be high priest at Jerusalem (i. 7). But we learn from 1 Chron. vi. 15 that Jehozadak filled that office the fifth year after Jerusalem was destroyed. In i. 2 there is an error. The city was not burned when Jehoiachim was carried away. And if the allusion be to the destruction of the city by Nebuchadnezzar, the temple and its worship are supposed still to exist in i. 8–10. The particulars narrated are put into the fifth year of the exile; yet we read, "Thou art waxen old in a strange country" (iii. 10).

2. Supposing Baruch himself to have been the writer, books later than his time are used in the work. Nehemiah is followed, as in ii. 11 (comp. Nehem. ix. 10). But Eichhorn's language is too strong in calling the contents "a rhapsody composed of various writings belonging to Hebrew antiquity, especially Daniel and Nehemiah." [1]

The date of the work is given indefinitely in i. 2, "In the fifth year, and in the seventh day of the month, what time as the Chaldeans took Jerusalem, and burnt it with fire." The natural meaning of these words is, "The fifth year after the destruction of Jerusalem by Nebuchadnezzar," not "the fifth year of Jehoiachim's captivity." The day is given, not the month; and therefore De Wette conjectures that ἔτει should be μηνί; but MS. authority is against him. It is probable that the name of the month has dropped out, *i e., Sivan*. The Palestinian abode of the writer is pretty clear, especially from the melancholy view of death presented in ii. 17, iii. 19, resembling that in Psalms vi. 6, lxxviii. 18, ciii. 29. In Alexandria the Jews had attained to a clear idea of immortality, in Palestine not. The translation was made in Egypt, which accounts for various expressions savouring of Alexandrianism, as in iii. 23, 24, 26. There are evident points of contact between Daniel and Baruch, as appears from Baruch i. 15–18, which agrees almost verbally with Daniel ix. 7–10. So ii. 1, 2 coincide with Daniel ix. 12, 13; and ii. 7–17 with Daniel ix. 13–18. Hitzig thinks the two authors were identical, but this can hardly be allowed; for the tone and atmosphere of Baruch bear no perceptible trace of the Syrian persecutions or Maccabean struggle. Daniel borrowed from Baruch pretty closely in some passages. We suppose that the translator was separated from the author by a considerable period, probably 200 years. Perhaps the author lived about 300–290 B.C.

According to Jerome and Epiphanius, the Jews did not receive the book into their canon; nor is it in the lists given by Josephus, Melito, and others. It has been thought, however, that Origen considered it canonical, because in his catalogue of sacred books he gives Lamentations and "the epistle" along with Jeremiah; and Jeremiah's epistle formed a part of Baruch. The testimony of Origen on this point is perplexing; but it is conceivable that *some* Jews may have thought very highly of the book in his time, though its authority was not generally admitted among their co-religionists.[2] From the position which the book occupied in the Septuagint, *i.e.*, either before or after Lamentations, it was often considered an appendix to Jeremiah by the early Christians, and was regarded in the same light, and of equal authority. Hence the words of it were often quoted as Jeremiah's by Irenæus, Clemens Alexandrinus, and Tertullian. Cyril of Jerusalem reckons it with the canonical books, among the αἱ θεοπνεύστοι or θεῖαι γραφαί; and the epithets so applied cannot be explained away by Protestants.

The versions are the two Latin, a Syriac, and an Arabic. The Latin one in the Vulgate belongs to a time prior to Jerome, and is tolerably literal. Another, somewhat later, was first published by Jos. Maria Caro in 1688, and was reprinted by Sabatier, side by side with the ante-Hieronymian one, in his *Bibliorum Sacrorum Latinæ Versiones Antiquæ*.[3] It is founded upon the preceding one, and is less literal. The Syriac and Arabic versions, printed in the London Polyglott, are literal. The Hexaplar-Syriac version, made by Paul, bishop of Tela, in the beginning of the 7th century, has been published by Ceriani.[4] The most convenient editions of the Greek text are Tischendorf's, in the second volume of his Septuagint, and Fritzsche's in *Libri Apocryphi Veteris Testamenti Græce*, 1871. (See Davidson's *Introduction to the Old Testament*, vol. iii.; *Kurzgefasstes Exegetisches Handbuch zu den Apokryphen des alten Testaments, erste Lieferung;* Ewald's *Geschichte des Volkes Israel*, vol. iv.; De Wette's *Einleitung*, §§ 321–323; Welte's *Einleitung in die heiligen Schriften des A. T., zweyter Theil, dritte Abtheilung.*)

Epistle of Jeremy.—An epistle of Jeremiah's is often appended to Baruch, forming the sixth chapter. According to the inscription, it was sent by the prophet by God's command to the Jews who were to be carried captive to Babylon. The writer describes the folly and absurdity of idolatry in a declamatory style, with repetitions somewhat like refrains. Thus, in verses 16, 23, 29, 65 occurs the sentence, "Whereby they are known not to be gods; therefore fear them not;" "How should a man then think and say that they are gods," in 40, 44, 56, 64, 69; "How then cannot men perceive that they be no gods," in 49, 52. These and other repetitions are unlike Jeremiah's. The concluding verse is abrupt.

All the relation this epistle has to Jeremiah is, that the contents and form are derived from Jeremiah x. 1–16 and xxix. 4–23. Its combination with Baruch is purely accidental. It could not have been written by Jeremiah, though many Catholic theologians maintain that it was. The Hellenist betrays himself in a few sentences, as when he speaks of kings, verses 51, 53, 56, 59. Though Welte tries to prove that the epistle was written in Hebrew, which is

[1] *Einleitung in die apokryphischen Schriften des A. T.*, p. 382.

[2] See Welte's note on this point in Herbst's *Einleitung, erster Theil*, pp. 14, 15.

[3] See vol. ii. p. 734, &c.

[4] *Monumenta Sacra et Profana*, tom. i. fascic. 1.

consistent with Jeremiah's authorship, his arguments are invalid. The original is pure Hellenistic Greek. The warning against idolatry bespeaks a foreigner living out of Palestine. The place of its origin was probably Egypt; and the writer may have lived in the Maccabean period, as we infer from his making the exile last for seven generations, *i.e.*, about 210 years. Jeremiah, on the contrary, gives the time as 70 years in round numbers. The oldest allusion to the epistle is commonly found in 2 Maccab. ii. 2, where a few words are similar to the fourth verse of our epistle. But the appropriateness of the supposed reference is doubtful.

The old Latin version of the epistle, published by Sabatier, which is in the Vulgate, is literal. The Syriac is freer. The Arabic is more literal than the Latin. Both are in the London Polyglott. The Hexaplar-Syriac was published by Ceriani. (S. D.)

BARYTES, or BARYTA, an oxide (BaO) of the metal barium, usually prepared from the two most common ores of the substance, the sulphate and the carbonate of baryta. It is a highly caustic alkaline poisonous body, which with water forms a hydrate of baryta. On a commercial scale baryta is prepared from the native carbonate (Witherite) by exposing the mineral, mixed with one-tenth of its weight of lamp black, to a very high heat. It is now largely employed in the beet sugar manufacture for separating crystallized sugar from the molasses. A solution of the hydrated oxide, under the name of baryta-water, is of very great use in the chemical laboratory for precipitating metallic oxides, and on account of its sensitiveness to carbonic acid. Sulphate of baryta, or heavy spar, the cawk of miners, is a mineral of very high specific gravity (4·59), found abundantly in veins in the mountain limestone of England and frequently associated with metallic ores. When reduced to powder the white varieties are sometimes used as a pigment, but the powder is more frequently applied as an adulterant to white lead. Heavy spar is also used in the manufacture of pottery. The powdered carbonate of baryta is used to some extent in the manufacture of glass, taking the place of a part of the alkali in plate glass, and of some portion of red-lead in flint glass. Cassel green, or Rosenstiehl's green, is a pigment manufactured from the calcined manganate of baryta. Both the nitrate and the chloride are of great value as chemical reagents. The nitrate and chlorate are also used to produce a green light in pyrotechny.

BASE BALL, a game which holds the same position in the United States of America as cricket does in Great Britain. It was founded on the old British game of rounders, though many additions and alterations have been made. Americans do not appreciate the patience of Englishmen, and do not care to witness a cricket match which may extend to three days, and then remain undecided, whereas the average time of a base ball match is from two hours to two hours and a half. The first regular base ball society was the old Knickerbocker Club, founded at New York in the autumn of 1845; and for fifteen years the sphere of play was very limited. In the spring of 1860 the Excelsior Club was inaugurated at Brooklyn, New York, and the amateur element, in contradistinction to the professional, gave a marked impetus to the pastime. This club was second to none in the United States of America, either in social standing or as correct exponents of the game. The secession of the Confederate States soon after, and the sanguinary civil war which followed, was a serious interruption to national or other sports, and base ball became almost obsolete till the season of 1865. Then it began to spread throughout the Union, and to be recognized as a profession, not a few devoting their whole time to it and being paid for their services. Now there are hundreds of games played for every one ten years since. In the summer of 1874 the Boston Base Ball Club and the Athletic Base Ball Club of Philadelphia crossed the Atlantic and played a series of exhibition matches in England and Ireland; but, as anticipated, the pastime did not find favour with Englishmen or take root in British soil.

The scene chosen for the pastime should be a clear level piece of turf, not less than 500 feet by 350 feet. The following diagram shows the laying out of the ground.

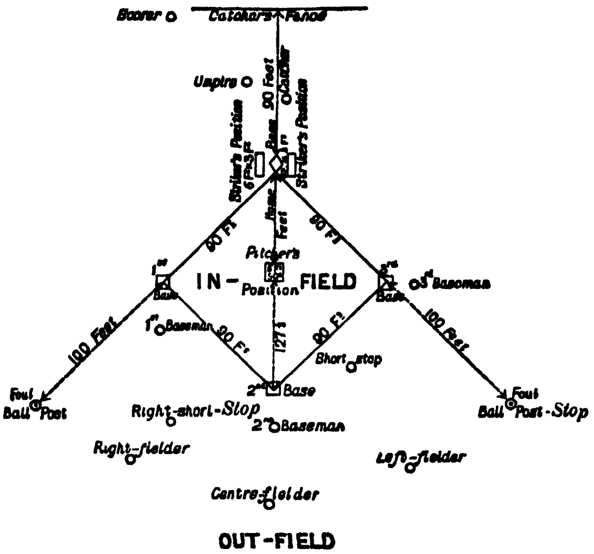

Diagram illustrating the Game of Base Ball.

The position of the bases and base lines may be likened to a 90 feet square shaped diamond. The first point to be selected is the rear angle of the home base, which should be not less than 90 feet from the most suitable end of the ground, and equi-distant from each side. Lay out this base 1 foot square, and from the front apex measure 127 feet 4 inches in a straight line down the ground, and the point reached will be the centre of the second base. Take a cord, 180 feet long, fixing one end on the front angle of the home base, and the other on the centre of the second base. By hauling the centre of this cord taut on the two sides, two isosceles right angled triangles will be formed, and the 90 feet square completed. Standing on the home base and looking down the ground, the apex of the triangle on the right hand is the centre of the first base, and of that on the left hand the centre of the third base. 48 feet from the front angle of the home base has then to be measured down the diagonal of the square, in order to fix the centre of the pitcher's position, which is 6 feet square. Lastly come the foul ball posts, which are on a line with the home and first bases, and home and third bases, and not less than 100 feet from the centres of first and third bases respectively.

Formerly, nine a side was the usual number of players; but, latterly, an additional man has been introduced as right short-stop, and the sides increased to ten. Their positions are marked in the above diagram. The theory of the game is that one side takes the field, and the other goes in. The pitcher then delivers the ball to the striker, who endeavours to hit it in such a direction as to elude the fielders, and enable him to run round all the base lines home without being put out. If he succeeds a run is scored. When three players are put out the fielding side come in: and after nine innings have been played the side which have scored the most runs wins the game. The rules are voluminous and minute, but the pith of them may be gleaned from the following résumé:—

The ball must weigh not less than 5 ounces or more than 5¼ ounces avoirdupois, must be not less than 9 inches or more than 9¼ inches in circumference, and must be composed of 1 ounce avoirdupois of vulcanized india-rubber, covered with worsted and leather, red being the most suitable colour for the latter. The bat must be circular in shape, not exceeding 2½ inches in diameter at any part, or 42 inches in length, and must be made exclusively of wood. The bases shall be 1 foot square, the first, second, and third consisting of white canvas

bags securely fastened to the ground, and the home base of white stone or marble, level with the ground, and with one angle facing the pitcher. Unless five innings on each side are concluded it is no game. No game can be drawn, unless play is stopped by darkness or the weather, when the score of the two sides is even. The pitcher's position shall be within a 6 feet square, the front of which shall be 45 feet from the centre of the home base, and the centre equidistant from the centre of first and third bases, each angle being marked by a flat iron or stone plate 6 inches square. In delivering the ball, the pitcher must not move either foot outside the limits of the square, and the hand must not be raised higher than the hip. All balls delivered over the home base, and at the height requested by the striker, are fair balls. All other balls are unfair or called balls, and if three occur in succession the striker is allowed to take the first base, and any other players move on a base accordingly. A striker may, however, take an unfair ball at his own risk. Balking, or pretending to deliver the ball and not doing so, is inadmissible, and any player, on first, second, or third base, is allowed to run a base whenever balking is attempted. If, after being warned by the umpire, three balks are made during the same innings, the out side at once forfeit the game. A ball which hits the bat without being struck at, or the person of the striker or umpire, is a dead ball and out of play. The striker shall stand in a space of ground 6 feet by 3 feet, on either side of the home base, extending 2 feet in front and 4 feet behind the centre thereof, and the inside 1 foot from the outside angle thereof, otherwise it is a foul strike. The striker may call for a high ball, which shall be delivered above his waist, but below his shoulder, or a low ball, *i.e.*, below his waist, but not within 1 foot of the ground. Should the striker fail to strike three fairly delivered balls, he must run the first base. The foul ball lines are unlimited in length, and shall extend in a straight line from the front angle of the first base through the centres of first and third bases respectively. A ball is fairly hit if it first touches the ground, a player's person, or other object, on or in front of the foul ball lines. A batsman is out—(1.) If a fair ball be caught before touching the ground, no matter how held by the fielder catching it, or whether the ball first touches the person of another fielder or not, provided it be not caught by the cap; (2.) If a foul ball be similarly held, or if it be so held after touching the ground but once; (3.) If a fair ball be securely held by a fielder while touching the first base with any part of his person before the base-runner touches said base, after hitting a fair ball; (4.) If the batsman, after striking three times at the ball and failing to hit it, and, running to first base, fails to touch that base before the ball is legally held there; (5.) If, after the batsman has similarly failed to hit the ball, it be caught either before touching the ground, or after touching the ground but once; (6) If the batsman wilfully strikes at the ball to hinder the ball from being caught; (7.) If the batsman hit the ball on a called foul strike, and it be caught either fair or foul, or if he make two called foul strikes. Directly a striker has fairly struck a fair ball he becomes a base-runner; starting from the home base to first base, thence to second, third, and home bases respectively, all bases being invariably run in this order. No base-runner is compelled to vacate his base except by the striker's striking a fair ball. The lines from base to base are 3 feet wide, clearly marked out on the turf, and a base-runner who leaves the base line to avoid being touched by the ball in the hands of a fielder is out. A run is scored when any base-runner reaches the home base again, after touching all the other bases in proper succession, and provided three players are not put out. No base can be run, or run scored, when a fair strike is caught before touching the ground, unless the base-runner returns to the base he started from, which he cannot leave again until the ball is held by the pitcher, wherever that fielder may happen to be. No unavoidable obstruction may be offered to any base-runner keeping the base lines. A base-runner is out—(1.) If, while the ball is in play, he be touched by a fielder with the ball in hand, when no part of his person is touching a base; and should the said fielder, while in the act of touching the base-runner, have the ball knocked out of his hand, the base-runner so touched shall be declared out; (2.) If the ball be held by a fielder on the first base before the base-runner, after hitting a fair ball, touches that base; but if a fielder holding the ball, and a base-runner touch a base simultaneously, the latter shall not be declared out; (3.) If he fail to touch the base he runs for, the ball being held by a fielder, while touching said base, before the base-runner returns and touches it; (4.) If he in any way interfere with or obstruct a fielder while attempting to catch a fair fly-ball or a foul ball; (5.) If he wilfully obstruct a fielder from fielding a ball; (6.) If he intentionally kick the ball or let it strike him. The umpire must be thoroughly conversant with the game and all minutiæ of the rules. He is the sole arbiter of every point of play, whether pitching, catching, fielding, striking, or running the bases.

The catcher's duty is to catch all balls pitched to the striker. He stands close to the striker's position when the pitching is slow, and some 50 feet off when it is swift. He must be a sure catch in order to catch the striker out when opportunity occurs, and a swift and accurate thrower of the ball to the basemen. The pitcher is the most responsible person on the outside. His great object is to deceive the striker as to where a ball is coming, and he must therefore have full command over the ball, besides possessing the nerve to face any catches hit straight at him. The first, second, and third basemen must all be sure catchers, swift and accurate throwers, and good judges of which bases to send the ball to in order to put an opponent out. The short-stop must be an active man, of great coolness and judgment, a general backer-up of the in-field. He is placed near the line from second to third base. The right, centre, and left fielders must all be sure catchers, good long distance throwers, and active runners. Right short-stop is generally the captain of the side, and is available either in this position or anywhere else where an extra hand is required. Having less work to do than any other fielder, he has better opportunities of attending to his general duties of supervision. The usual positions of all the fielders are defined in the diagram. The catcher, pitcher, first and third basemen, and short-stop comprise the in-field; the remainder the out-field.

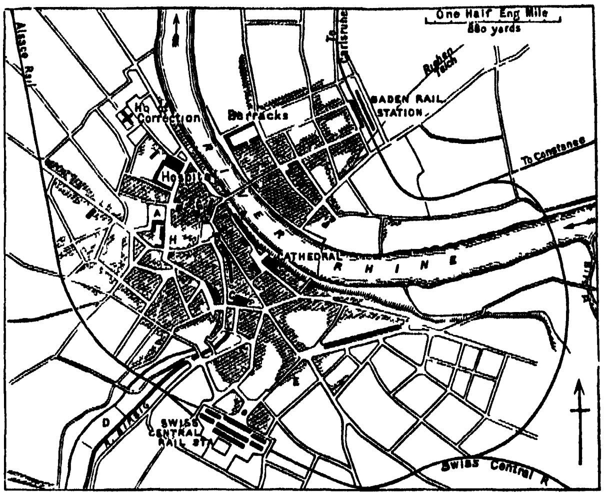
The pastime requires good catching, throwing, and running powers, combined with courage, nerve, good judgment, and quick perception of what to do in the field. The great draw-back is so much being left to the umpire, and his decision being so frequently called for. Hardly a ball is pitched or struck, or a base run without his being called on for a decision under some rule or other, whereas the details of the game should be so plain and clear as only to call for an umpire's decision under exceptional circumstances. The attitude of the striker is not an elegant one, and the pitcher is allowed to keep the former's muscles too long on the stretch before actually delivering the ball. Base ball is a quicker and more lively pastime than the great English national game of cricket, which is the chief thing to be said in its favour. (H. F. W.)

BASEDOW, Johann Bernhard, a German author, born at Hamburg 11th September 1723, was the son of a hairdresser. He was educated at the Johanneum in that town, where he came under the influence of the well-known rationalist, H. S. Reimarus, author of the *Wolfenbüttel Fragments*. In 1744 he went to Leipsic to study theology, and gave himself up entirely to the instructions of Professor Crusius, and to the study of philosophy. This at first induced sceptical notions; a more profound examination of the sacred writings, and of all that relates to them, brought him back to the Christian faith, but, in his retirement, he formed his belief after his own ideas, and it was far from orthodox. He returned to Hamburg, where in 1749, M. de Quaalen, privy-councillor of Holstein, appointed him preceptor to his son. Basedow now began to exhibit his really remarkable powers as an educator of the young, and acquired so much distinction that, in 1753, he was chosen professor of moral philosophy and belles-lettres in the academy of Soroë in Denmark. On account of his theological opinions he was removed from this post and transferred to Altona, where some of his published works brought him into great disfavour. He left off giving lessons without losing his salary; and, towards the end of 1767, he abandoned theology to devote himself with the same ardour to education, of which he conceived the project of a general reform in Germany. He began by publishing *An Address to the Friends of Humanity, and to Persons in Power, on Schools, on Education, and its Influence on Public Happiness, with the Plan of an Elementary Treatise on Human Knowledge*, Hamburg, 1768. He proposed the reform of schools and of the common methods of instruction, and the establishment of an institute for

qualifying teachers,—soliciting subscriptions for the printing of his elementary work, where his principles were to be explained at length, and illustrated by plates. The subscriptions for this object amounted to 15,000 thalers (£2250), and in 1774 he published his *Elementary Work*, a complete system of primary education, intended to develop the intelligence of the pupils and to bring them, so far as possible, into contact with realities, not with mere words. The work was received with great favour, and Basedow obtained means to establish an institute for education at Dessau, and to apply his principles in training disciples, who might spread them over all Germany. Little calculated by nature or habit to succeed in an employment which requires the greatest regularity, patience, and attention, he, however, engaged in this new project with all his accustomed ardour. The name of *Philanthropin* appeared to him the most expressive of his views; and he published at Leipsic in 1774 a pamphlet entitled *The Philanthropinon founded at Dessau*, containing the details of his plan. He immediately set about carrying it into execution; but he had few scholars, and the success by no means answered his hopes. Nevertheless, so well had his ideas been received, that similar institutions sprang up all over the land, and the most prominent writers and thinkers openly advocated the plan. Had Basedow been a man of ordinary tact, his success would have been complete. But his temper was intractable, and his management was one long quarrel with his colleagues. The institution was finally shut up in 1793. Basedow died at Magdeburg on the 25th July 1790. Notices of his life and works have been published by Rathmann (1791) and Meyer (1791–2).

BASEL, BÂLE, or BASLE (the first being the German, the others the French and Old French forms of the name), a canton in the N.W. of Switzerland, with an area of 184 English square miles. It is bounded on the N.W. by Alsace, N. by the grand-duchy of Baden, E. by the canton of Aargau, and S. and S.W. by those of Solothurn and Berne. The canton is traversed by the Jura chain, the highest peaks of which rise to from 4000 to 5000 feet. With the exception of the Rhine and its tributaries,—the Birse and the Ergolz,—there are no streams of any magnitude. The soil is for the most part fertile and well cultivated, the mountain sides affording excellent pasturage. The principal pursuits of the people are agricultural and pastoral, though here and there, as at Liestal, Sissach, and Munchenstein, coal-mining is carried on. The chief manufactures are ribbons, woollen, linen, and cotton goods, and iron and steel wares. Politically the canton consists of two divisions, one urban and the other rural (Basel-stadt and Basel-landschaft), each with its own constitution and laws. The former sends two members to the National Council; its legislative power is in the hands of a Great Council which consists of 134 members, chosen for six years, and its executive power belongs to a Lesser Council of 15 members. In the rural division the legislative body (or *Landrath*) is chosen for three years, and has the ultimate authority over all departments; the executive council consists of five members elected for the same period; it sends three members to the National Council. The prevailing language is German. Population of Basel-stadt in 1870, 47,760, and of Basel-landschaft, 54,721.

BASEL, or BÂLE, the capital of the above canton, and, next to Geneva, the largest city in Switzerland, is situated on both sides of the Rhine, 43 miles N. of Berne, in lat. 47° 33′ N., and long. 7° 35′ E. Great Basel, or the city proper, lies on the south side of the river, and is connected with Little Basel on the north side by a handsome bridge 800 feet long, which was originally erected in 1229. The city is generally well-built, but there are fewer remarkable edifices than in many other Continental cities of similar size. The fine old Gothic cathedral, founded 1010, still stands, and contains a number of interesting monuments, besides the tombs of Erasmus, Œcolampadius, and other eminent persons. A re-decoration was skilfully effected in 1852–1856. Among other ecclesiastical buildings of interest may be mentioned St Martin's, restored in 1851; St Alban's, formerly a monastery; the church of the Bare-footed Friars, which now serves as a store-house; Elizabeth's Church, of modern erection; and St Clara's in Little Basel. The town-hall was built in 1508 and restored in 1826. A post-office, a new bank, and an hospital are of recent erection. Besides the university,



Plan of Basel.

B, Market.	F, University.
C, Barfusser Platz.	G, Town-Hall.
D, Zoological Gardens.	H, Armoury.

which was founded by Pope Pius II. in 1459, and reorganized in 1817, Basel possesses a public library of 95,000 vols., with a valuable collection of MSS., a picture-gallery, a museum, a theological seminary for missionaries (established in 1816), a gymnasium, an industrial school, a botanical garden, an orphan-asylum, an institution for deaf-mutes, and various learned societies. Of these may be mentioned the Society for the Propagation of Useful Knowledge, founded in 1777 by Iselin, the Society of Natural History, the Society of National Antiquities, and the Bible Society, which dates from 1804 and was the first of the kind on the Continent. Basel is the seat of an active transit-trade between France, Germany, and Switzerland, and possesses important manufactures of silk, linen, and cotton, as well as dyeworks, bleachfields, and ironworks, the most valuable of all being the ribbon-trade. It has railway communication with both south and north. The Baden line has a station in Little Basel; and the central station for the Swiss and Alsace railways lies to the south-east of the city proper. Basel was the birthplace of Euler, Bernouilli, Iselin, and perhaps of Holbein; and the names of Erasmus, Œcolampadius, Grynæus, Merian, De Wette, Hagenbach, and Wecknernagel, are associated with the university. Population in 1870, 44,834.

Basel (*Basilia*) first appears in the 4th century as a Roman military post. On the decay of the neighbouring city of *Augusta Rauracorum*, the site of which is still marked by the village of Augst, it began to rise into importance, and, after numerous vicissitudes, became a free city of the empire about the middle of the 10th century, and obtained a variety of privileges and rights. In 1356 the most of its buildings were destroyed by an earthquake.

In 1392 the town of Little Basel was acquired from the bishop by purchase. From 1431 to 1443 the meetings of a General Council were held in the city (see next article). After the battle of St Jacob in 1444, in the immediate neighbourhood, Basel was visited by the plague, and its population considerably diminished. In 1501 it became a member of the Swiss Confederacy; and it was one of the chief seats of the Reformation movement. The position of the city exposed it to many dangers during the Thirty Years' War and the subsequent disturbances of the neighbouring states; but in spite of all it continued to flourish. A peril of a more critical kind arose from within. The quasi-aristocratic Government of the city appropriated all political rights, and left the inhabitants of the rural districts unrepresented,—which gradually led to much discontent on the part of the latter, and ultimately to actual rebellion. It was not till 1833 that peace was firmly restored by the complete separation of the canton into the two divisions of *Basel-stadt* and *Basel-landschaft*, the former being allowed to include not only the city proper, but also the communes of Reihen, Bettingen, and Klein-Hüningen. The capital of the rural division is Liesthal, with (in 1870) a population of 3873.

BASEL, THE COUNCIL OF (1431–1443), was the last of the three great reforming councils of the 15th century, coming after the councils of Pisa (1409) and Constance (1414–18). In these three councils the aim of the majority was to reform the church by destroying the absolute supremacy of the Pope, and by curbing the rule of the Roman curia; and the acts of these councils were all designed to re-establish the power of the episcopate by asserting the supremacy of œcumenical councils. At Pisa these aims were only indicated; at Constance they were so far successful that schismatic popes were deposed, and the council practically showed its superiority to the Pope by bestowing the papal chair on Martin V.; and although the fathers of Constance were compelled to separate before they could do much else in the way of reform, they practically laid the foundation by insisting that councils should be held frequently, and by ordering a new council to be called at the end of five years. The council summoned in obedience to this command was the Council of Basel, but the results of its meeting were simply to show the helplessness of the episcopate and the power of the Roman curia. At Basel the labours of Pisa and Constance were undone, and after this council thoughtful men began to see that the church could not be reformed without destroying the Papacy.

The Council of Basel was summoned by Martin V. (1431). He first appointed it to meet at Pavia, then at Siena, but Basel was at last fixed upon. At the very beginning Martin died, but his successor, Eugenius IV., sanctioned all his decrees; and the council accordingly met at Basel on the 23d of July 1431, under the presidency of Cardinal Julian Cesarini. At first all went well. The bishops took care so to arrange the organization of the council and its method of procedure as to make it a true and fair representative of the whole Catholic Church. The members of the council were divided into four equal classes, each consisting of about the same number of cardinals, archbishops, bishops, abbots, &c., and each completely organized, with its president, secretaries, and other officers. This was done to neutralize the votes and prevent the intrigues of the Italian bishops, who were very numerous, and for the most part under the power of the Roman curia. To each of the four was assigned the investigation of a special class of subjects. Each section met separately in its own hall thrice a week. Each section elected three of its number to form a committee of business. One-third of this committee was changed every month. All the business had to pass through this committee, and it sent down special subjects to be discussed in each of the sections. When the section had discussed the matter it sent its decision with the reasons of it to each of the other sections, who then discussed the matter and gave their opinion upon it. If three sections were agreed upon it, the subject was brought before the whole council for general discussion and a final decision.

The three subjects which were specially assigned to this council were the reunion of the Greek and Latin Churches, the reconciliation of the Bohemians, and the reform of the church according to the resolutions come to at Constance. Soon after the beginning of the council the Roman curia took alarm at the zeal and determination of the assembled bishops, and by intrigues compelled the Pope, who was really anxious for reform, to do all he could to hinder the work of the fathers at Basel. Eugenius twice tried to dissolve the council; but it resisted, maintaining that a council being superior to the Pope could not be dissolved, and the Pope yielded. The bishops refused to admit the Pope's legates until they admitted the supremacy of the council and promised to obey its decrees.

The first business to which the members addressed themselves was to curb the power of the Pope and of the Roman curia. They tried to do this by attempting to stop the flow of money from all parts of Europe to Rome. They abolished the annates; they declared it illegal in a bishop to send the sum of money commonly presented on his investiture, &c.; and they passed many laws to restrain the luxury and vice of the clergy. These proceedings so alarmed Eugenius that he resolved either to bring the council within the reach of his influence or to dissolve it. The occasion for interference arose out of a debate which the subject of reunion with the Greek Church gave rise to. The Emperor John Palæologus, induced principally by fear of the Turks, had written both to the Pope and to the council on the subject of the reunion of Christendom, and both had entertained his proposals. The majority, however, of the bishops in the council maintained that this subject could not properly be discussed in Italy, and that the deliberations must take place in France, Savoy, or Basel, far from the influence of the Pope. To this Eugenius would not agree; and when the council decided against him, he resolved to assemble another council, which met first at Ferrara and afterwards at Florence.

The rest of the proceedings of the Council of Basel is simply a record of struggles with the Pope. In 1437 the council ordered the Pope to appear before them at Basel. The Pope replied by dissolving the council; the bishops, backed by the emperor and the king of France, continued their deliberations, and pronounced the Pope contumacious for not obeying them. When Eugenius tried to take away the authority of the council by summoning the opposition Council of Florence, the bishops at Basel deposed him. Eugenius replied by a severe bull, in which he excommunicated the bishops, and they answered by electing a new Pope, Amadeus, duke of Savoy, who assumed the name of Felix V. The greater part of the church adhered to Eugenius, but most of the universities acknowledged the authority of Felix and the Council of Basel. Notwithstanding the opposition of Eugenius and his adherents, the Council of Basel continued to pass laws and decrees until the year 1443; and when the bishops separated they declared publicly that they would reassemble at Basel, Lyons, or Lausanne. In 1447 Eugenius died and was succeeded by Nicholas V., who tried to bring about a reconciliation between the parties in the church. A compromise was effected, by which Felix resigned the pontificate, and the fathers of Basel having assembled at Lausanne, ratified the abdication of Felix, and directed the church to obey

Nicholas, while Nicholas confirmed by his sanction the acts and decrees of the Council of Basel.

Hefele's *Conciliengeschichte*, vol. v.; Mansi, *Concilia*, vol. xxix; Æneas Sylvius, *De Concilio Basiliensi*. The *Acts* of the Council are preserved in MS. in Paris and in Basel. (T. M. L.)

BASHAN, a country lying on the east side of the Jordan valley, towards its northern extremity, often mentioned in Jewish history. The Hebrew form of the name is בָּשָׁן or הַבָּשָׁן, represented in Greek by Βασάν and Βασανῖτις (LXX. and Epiphanius), or more frequently by Βαταναία (Josephus, Ptolemy, Eusebius, &c.). The name is understood to be derived from a root signifying *fertile*, or, according to some, *basaltic*; and in some of the ancient versions of the Old Testament it is occasionally rendered by a word indicating fertility; thus, in Ps. xxii. 13, the LXX. gives for Bashan πίονες, Aquila gives λιπαροί, Symmachus, σιτιστοί. When we first hear of this region in the days of Abraham it is occupied by the Rephaim, whose chief city is Ashteroth Karnaim (Gen. xiv. 5). These Rephaim, with kindred tribes spread over the trans-Jordanic region, were in great part subdued and supplanted by the children of Lot (Deut. ii. 10, 11, 19–21), who in their turn were invaded and displaced by the Amorites (Num. xx. 26–30). By this people, at the time of the Exodus, the whole region north of the Arnon was occupied; and they formed two kingdoms, the more northerly embracing all Bashan and a part of Gilead (Deut. iii. 8, 13; Josh. xii. 4, 5). Og, who is described as a man of gigantic stature, belonging to the race of the Rephaim, was, at the time referred to, the ruler of this kingdom; and having come out against the Israelites, he was overthrown in battle at Edrei, one of his own cities. Subsequently, his country became the allotment of the half tribe of Manasseh (Josh. xiii. 29–31).

The information given in connection with the Israelitish conquest enables us to define with considerable exactness the limits of the ancient Bashan. Towards the west it included Golan (Deut. iv. 43; Josh. xx. 8, xxi. 27), a name which to the present day has continued attached to the district, the Jaulân, lying on the east of the Jordan, in its upper course; while towards the east, it reached to Salchah (Deut. iii. 10, &c.), the modern Salkhat, situated on the south-eastern slope of the Haurân mountains. On the south it is represented as immediately adjoining the country of Gilead, whose northern boundary is known to have been the river Jarmuk, and on the north, it is expressly said to have extended to Mount Hermon (Deut. iv. 48, xxxiii. 22; Josh. xii. 5, xiii. 11, 12). Within the limits thus indicated, may be pointed out the towns and other localities mentioned as belonging to Bashan. Ashtaroth, Og's metropolis, doubtless the Ashteroth Karnaim of Gen. xiv. 5, called also Beeshterah (*cf.* Josh. xxi. 27, and 1 Chron. vi. 71), has been sought in various places, especially in Tel Ashtereh (see Newbold, *Jour. Geog. Soc.*, vol. xvi.), but has now, with much probability, been identified (by Wetzstein, *Reisebericht uber Haurân*, p. 110) with the well known Busrâh, the Bostra of the Latins, whose position admirably adapts it for a capital city, and whose ruins attest its ancient splendour. Edrei, already mentioned, is to be identified with Derât, on the west of Busrâh (Wetzstein, *op. cit.*, p. 47, 77). The position of Golan and Salchah has been indicated, while Kenath (Num. xxxii. 42) is recovered in the modern Kunawât (Porter, *Five Years in Damascus*, vol. ii. p. 111). The region of Argob will be referred to immediately.

Within the same limits lie the provinces included by Josephus in the Bashan of the Israelites (*cf. Ant. Jud.*, iv. 5, 3; ix. 8, 1; *Bell. Jud.*, ii. 6, 3; iii. 3, 5), and recognized generally by the Greek and Roman writers. They are four—Gaulonitis, Trachonitis, Auranitis, and Batanæa, answering as nearly as possible to the natural divisions of the country. The first, Gaulonitis, deriving its name from the ancient Golan, and coincident more or less exactly with the modern Jaulân already mentioned, forms the western division, extending from the Jordan lakes to the Haj road. It is spoken of as divided into two sections, the territory of Gamala, or Gamalitis, and the territory of Sogana (*Bell. Jud.*, iv. 1, 1). It forms a fertile plateau, diversified on its northern half by a range of low, richly-wooded hills, the Tell el Faras, which descends from Mount Hermon. The second, Trachonitis (mentioned Luke iii. 1), lay east of the preceding, and adjoined the territory of Damascus, as well as Auranitis and Batanæa (*Ant. Jud.*, i. 6, 4; xv. 10, 1). This leads us to the remarkable tract, now called the Lejâh, forming one of the two Trachônes, or rocky volcanic districts, lying south and east of Damascus, mentioned by Strabo (*Geog.* xvi. p. 520). Inscriptions, moreover, have been found in the Lejâh (see Burckhardt, *Travels in Syria*, p. 117), which attest that the district was called Trachôn. In this province we may with confidence recognize "the region of Argob," so often mentioned in the Old Testament, as included in the country of Bashan (Deut. iii. 4, 13, 14; 1 Kings iv. 13). The arguments for this identification are,—1st, The etymology of the word Argob (see Gesenius and Furst, *sub voce*); 2d, the descriptive term usually conjoined with the name, *chebel* Argob, indicating a tract clearly defined and measured off, and applied elsewhere to the line of the sea coast, which the boundary of the Lejâh resembles (*cf.* Porter, *op. cit.*, vol. ii. p. 241); 3d, by the Targumists the name Argob is rendered *Trachôna* (Lightfoot, *Chorographical Notes*, § 4). The third province, Auranitis, presents a name known both in ancient and in modern times. In Ezekiel (xlvii. 16, 18) mention is made of Haurân (in the LXX. Αὐρανῖτις), as a locality on the border of the land of Israel. The name is found also on the inscriptions of Assyria, under the form Havranu (Schrader, *Die Keilinschriften und das A. T.*, p. 237), and it is common in Arabian writers. In regard to its modern use Porter says (*Jour. Sac. Lit.*, July 1854, p. 303), "The name Haurân is at present applied by those at a distance to the whole country east of Jaulân and Jeidûr. By the people of that country, however, it is used in a much more restricted sense, and is given only to the fertile plain on the south of the Lejâh, with the narrow strip on the west. The whole of this district is perfectly flat, with little conical hills at intervals. The soil is the most fertile in Syria, admirably adapted to the production of wheat." (*Cf.* Burckhardt, *op. cit.*, p. 285.) The fourth district is Batanæa, a name obviously derived from, and often used by Josephus and others co-extensively with, the old name Bashan. It has, however, a special application to the district lying on the east of the Lejâh and of the Haurân plain, including the central masses of the Jebel ed-Druz or Haurân mountain (apparently the Alsadamus or Alsalamus mons of Ptolemy, and, perhaps, the Salmon of Ps. lxviii. 14; see Reland, *Palæstina*, p. 458; Wetzstein, *op. cit.*, p. 90) and its eastern slopes. To this portion of the kingdom of Bashan, the name Ard-el-Bathanyeh is still applied by the natives. Says Porter (*op. cit.*, p. 305), "One of the most intelligent Druzes I met with in my whole journey, told me the whole mountains were comprehended in the Ard-el-Bathanyeh."

The history of Bashan, after its conquest by the Israelites, merges into the general history of that nation, and of Western Asia. It is last mentioned in the Old Testament, in 2 Kings x. 33, in connection with the attacks made by Hazael, the king of Damascus, upon the territory of Israel. Throughout the Psalms and the Prophets, Bashan is celebrated for its fertility and luxuriance, its rich pastures, its strong bulls, its fatlings "of rams, of lambs, and of goats, of bullocks;" its oaks and its firs (Ps. xxii.

12; Amos iv. 1; Isa. ii. 13; Jer. l. 19; Ezek. xxxix. 18, xxvii. 6); and its extraordinary fertility is attested by the density of its population (Deut. iii. 4, 5, 14)—a density proved by the unparalleled abundance with which ruined towns and cities are now strewn over the whole country. In the disturbed period which followed the breaking up of the empire of Alexander, its possession was an object of continual contest. "Idumæan princes, Nabathæan kings, Arab chiefs, ruled in their turn." The central portion of the country, Trachonitis, early became a refuge for outlaws and haunt of robbers, a character for which it is singularly fitted by nature, and which it retains to the present day. (*Cf.* Josephus, *Ant. Jud.*, xv. 1; xvi. 9, 2; Strabo, *Geog.*, xvi. p. 520; Gul. Tyr., *Hist.*, xv. 10.) In Arabian tradition Bashan is regarded as the country of the patriarch Job (see Abulfeda, *Hist. Anteislamica*, p. 27, 208, and esp. Wetzstein, in Delitzsch, *Das Buch Job*, p. 507, *ff.*); and it holds a prominent place in authentic Arabian history as the seat of the dynasty of the Ghassanides (see Caussin de Perceval, *L'Histoire des Arabes*, vol. ii. 202, *f.*; Wetzstein, *op. cit.*, 121, *f.*) At the present day the Haurân is one of the seats of that singular people, the Druzes (see DRUZES).

Both in its natural and its archæological aspects, the country of Bashan is full of interest. The Jebel ed-Druz, which rises to nearly 6000 feet in height, is a congeries of extinct volcanoes, and the products of eruption from this source, spread over the adjoining plains, have given to the soil that character of fertility for which it has been in all ages remarkable. (*Cf.* Lyell, *Principles of Geology*, 9th ed., p. 394.) This volcanic soil, we are told, yields on the average, in some places, eighty returns of wheat, and a hundred of barley (Wetzstein, *op. cit.*, p. 30). The mountains themselves are richly clothed, at least on their western side, with forests of various kinds of trees, among which the evergreen oak is especially abundant. The Lejâh is one of the most remarkable regions on the earth's surface. "It is," says one of the latest observers (Burton, *Unexplored Syria*, vol. i. p. 164), "in fact a lava bed; a stone torrent poured out . . . over the ruddy yellow clay and the limestone floor of the Haurân valley, high raised by the ruins of repeated eruptions, broken up by the action of fumaroles or blow holes, and cracked and crevassed when cooling by earthquakes, and by the weathering of ages." (See also Burckhardt, *op. cit.*, p. 112; Porter's *Five Years in Damascus*, vol. ii. p. 241; Wetzstein, *op. cit.*, p. 25.)

In regard to the architectural monuments of the Haurân, the "striking feature," says Count de Vogüé (*Recovery of Jerusalem*, p. 423), "is the exclusive use of stone. The country produces no wood, and the only rock which can be obtained is a basalt, very hard and very difficult to work." The walls are formed of large blocks, carefully dressed, and laid together without cement, and often let into one another with a kind of dovetail. Roofs, doors, stairs, and windows, are all of stone. This, of course, imparts to the buildings great massiveness of appearance and great solidity, and in multitudes of cases the houses, though "without inhabitant," are as perfect as when first reared. Since buildings so strong are apparently capable of enduring for any length of time, and since some of these are known, from the inscriptions upon them, to date from before the commencement of the Christian era, it is not unnatural to regard them as, in fact, the work of the earliest known inhabitants of the land, the Amorites or the Rephaim. (See Ritter, *Paläst. und Syrien*, ii. 964; Porter, *Giant Cities*, p. 79, *f.*) This, however, is contested, on the ground that the extant inscriptions and the architectural style point to a much later date, and must be regarded as at least unproved. (See Wetzstein, *op. cit.*, p. 103; Fergusson, in *Athenæum*, July 1870, p. 148; Burton, *op. cit.*, vol. i. p. 192.) Many inscriptions have been found in this region,—most of them composed in Greek, a considerable number in two forms of Shemitic writing (the Palmyrenian or Aramæan, and the Sinaitic or Nabathæan), and some in an unknown character, resembling the Himyaritic. Arabic inscriptions are numerous on buildings of more recent date. The oldest recognizable Greek record bears the name of Herod the Great; and the Nabathæan kings, of the dynasty of Aretas, who reigned from about 100 B.C. at Bozrah have also left memorials.

To the works on this region above referred to the following may be added:—Seetzen, *Reisen durch Syrien*; Buckingham, *Travels among the Arab Tribes*; Graham, *Jour. Geog. Soc.*, vol. xxviii.; De Vogüé, *Syrie Centrale*; Waddington, *Inscriptions Grecques de la Syrie*; Freshfield, *Travels in the Central Caucasus and Bashan.* (W. TU.)

BASHKIRS, a people who inhabit the Russian governments of Orenburg, Perm, and Samar, and parts of Viatka, especially on the slopes and confines of the Ural, and in the neighbouring plains. The Bashkirs are a Tatarized Finnish race, and are called Eestyak by the Kirghiz, in allusion to their origin from a mixture of Ostyaks and Tatars. The name Bashkir or Bash-kûrt appears for the first time in the beginning of the 10th century in the writings of Ibn-Foslan, who, describing his travels among the Volga-Bulgarians, mentions the Bashkirs as a warlike and idolatrous race. The name was not used by the people themselves in the 10th century, but is a mere nickname. It probably points to the fact that the Bashkirs, then as now, were distinguished by their large, round, short, and, possibly, close-cropped heads. Of European writers the first to mention the Bashkirs are Plano-Carpini and Rubruquis. These travellers, who fell in with them in the upper parts of the River Ural, call them Pascatir, and assert that they spoke at that time the same language as the Hungarians. Till the arrival of the Mongolians, about the middle of the 13th century, the Bashkirs were a strong and independent people, and troublesome to their neighbours, the Bulgarians and Pechenegs. At the time of the downfall of the Kazan kingdom they were in a weak state. In 1556 they voluntarily recognized the supremacy of Russia, and, in consequence, the city of Upha was founded to defend them from the Kirghiz, and they were subjected to a fur-tax. In 1676 they rebelled under a leader named Seit, and were with difficulty reduced; and again in 1707, under Aldar and Kûsyom, on account of ill-treatment by the Russian officials. Their third and last insurrection was in 1735, at the time of the foundation of Orenburg, and it lasted for six years. In 1786 they were freed from taxes; and in 1798 an irregular army was formed from among them. They are now divided into thirteen cantons, and each canton into yûrts or districts, the whole being under the jurisdiction of the Orenburg governor-general. In military matters they are subject to an Ataman, chosen from the generals of the army; but in civil affairs the yûrts and cantons are administered by Bashkir officials. They maintain a military cordon, escort caravans through the Kirghiz steppes, and are employed in various other services. By mode of life the Bashkirs are divided into settled and nomadic. The former, who are not distinguishable from the inhabitants of the Tatar villages, are engaged in agriculture, cattle-rearing, and bee-keeping, and live without want. The nomadic portion is subdivided, according to the districts in which they wander, into those of the mountains and those of the steppes. Almost their sole occupation is the rearing of cattle; and they attend to that in a very negligent manner, not collecting a sufficient store of winter fodder for all their herds, but allowing part of them to perish. The Bashkirs are usually very poor, and in winter live partly on a kind of gruel called yûryu, and badly prepared cheese named skûrt. They are hospitable but suspicious, apt to plunder, and to the last degree lazy. They have

large heads, black hair, eyes narrow and flat, small foreheads, ears always sticking out, and a swarthy skin. In general, they are strong and muscular, and capable of enduring all kinds of labour and privation. They profess Mahometanism, but are little acquainted with its doctrines. In intellectual development they do not stand high.

See Semenoff, *Slovar Ross. Imp. s. v.*; Frahn, "De Baskiris," in *Mém. de l'Acad. de St Petersburg*, 1822; and Florinsky, in *Westnik Evropi*, 1874.

BASIL THE GREAT, an eminent ecclesiastic in the 4th century. He was a leader in the Arian controversy, a distinguished theologian, a liturgical reformer; and his letters to his friends, especially those to Gregory of Nazianzus, give a great amount of information about the stirring period in which he lived. Basil came of a somewhat famous family, which gave a number of distinguished supporters to the church of the 4th century. His eldest sister, Macrina, was celebrated for her saintly life; his second brother was the famous Gregory of Nyssa; his youngest was Peter, bishop of Sebaste; and his eldest brother was the famous Christian jurist Naucratius. It has been observed that there was in the whole family a tendency to ecstatic emotion and enthusiastic piety. Basil was born about 330, at Cæsarea in Cappadocia. While he was still a child, the family removed to Pontus; but he soon returned to Cappadocia to live with his mother's relations, and seems to have been brought up by his grandmother Macrina. It was at Cæsarea that he became acquainted with his life-long friend Gregory of Nazianzus, and it was there that he began that interesting correspondence to which reference has been made. Basil did not from the first devote himself to the church. He went to Constantinople in pursuit of learning, and spent four or five years there and at Athens. It was while at Athens that he seriously began to think of the church, and resolved to seek out the most famous hermit saints in Syria and Arabia, in order to learn from them how to attain to that enthusiastic piety in which he delighted, and how to keep his body under by maceration and other ascetic devices. After this we find him at the head of a convent near Arnesi in Pontus, in which his mother Emmilia, now a widow, his sister Macrina, and several other ladies, gave themselves to a pious life of prayer and charitable works. He was not ordained presbyter until 365, and his ordination was probably the result of the entreaties of his ecclesiastical superiors, who wished to use his talents against the Arians, who were numerous in that part of the country, and were favoured by the Arian emperor, who then reigned in Constantinople. In 370 Eusebius, bishop of Cæsarea, died, and Basil was chosen to succeed him. It was then that his great powers were called into action. Cæsarea was an important diocese, and its bishop was, *ex officio*, exarch of the great diocese of Pontus. Basil was threatened with confiscation of property, banishment, and even death, if he did not relax his regulations against the Arians; but he refused to yield, and in the end triumphed. He died in 379. The principal theological writings of Basil are his *De Spiritu Sancti* and his three books against Eunomius. He was a famous preacher, and we possess at least seventeen homilies by him on the Psalms and on Isaiah. His principal efforts as a reformer were directed towards the improvement of the Liturgy (the *Liturgy of the Holy Basil*), and the reformation of the monastic orders of the East. (*Cf.* the Benedictine editions of the works of Basil the Great.)

The name Basil also belongs to several distinguished churchmen besides Basil the Great. (1.) Basil, bishop of Ancyra (336–360), a semi-Arian, highly favoured by the Emperor Constantine, and a great polemical writer; none of his works are extant. (2.) Basil of Seleucia (fl. 448–458), a bishop who shifted sides continually in the Eutychian controversy, and who wrote extensively; his works were published in Paris in 1622. (3.) Basil of Ancyra, fl. 787; he opposed image worship at the second council of Nicæa, but afterwards retracted. (4.) Basil, the founder of a sect of mystics who appeared in the Greek Church in the 12th century (*cf.* Anna Comnena, *Alexiad*, bk. 15).

BASILICA, a term denoting (1) in civil architecture, a court of law, or merchants' exchange, and (2) in ecclesiastical architecture, a church of similar form and arrangement.

The name *basilica*, βασιλική (sc. στοά or αὐλή), "a royal portico," or "hall," is evidence of a Greek origin. The portico at Athens in which the second archon, ἄρχων βασιλεύς, sat to adjudicate on matters touching religion, and in which the council of Areopagus sometimes met, was known as the στοά βασίλειος or βασιλική (Pausan., i. 3, § 1; Demosth., *Aristogit.*, p. 776; Plato, *Charmid.*, *ad init.*; Aristoph., *Ecclesiaz.*, 685). From this circumstance the term appears to have gained currency as the designation of a law-court, in which sense it was adopted by the Romans. The introduction of *basilicæ* into Rome was not very early. Livy expressly tells us, when describing the conflagration of the city, 210 B.C., that there were none such then,—"neque enim tum basilicæ erant" (xxvi. 27). The earliest named is that erected by M. Porcius Cato, the censor, 183 B.C. (Liv., xxxix. 44), and called after its founder *basilica Porcia*. When once introduced this form of building found favour with the Romans. As many as twenty basilicæ are recorded to have existed within the walls of Rome, erected at different periods, and bearing the names of their founders, *e.g.*—*Æmilia*, *Julia*, *Sempronia*, *Ulpia* or *Trajani*, &c. The basilicas were always placed in the most frequented quarter of the city in the immediate vicinity of a forum, and on its sunniest and most sheltered side, that the merchants and others who resorted thither might not suffer from the severity of the weather (Vitruv., *De Architect.*, v. 1). Originally, the basilicas, like the Royal Exchange in London and the Bourse at Antwerp, were unroofed, consisting of a central area surrounded simply by covered porticoes, without side walls. Subsequently, side walls were erected and the central space was covered by a roof, which was generally of timber, the beams being concealed by an arched or coved ceiling, ornamented with *lacunaria*. Some basilicas (*e.g.* that of Maxentius or "the Temple of Peace") were vaulted.

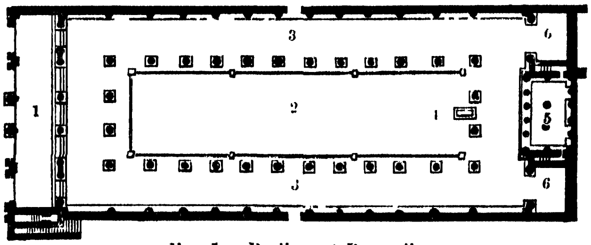

Fig. 1.—Basilica at Pompeii

1. Portico | 4 Altar.
2 Hall of Basilica | 5. Tribunal.
3. Side aisles, with galleries over. | 6. Chalcidica.

In plan the basilicas were large rectangular halls, the length of which, according to the rules laid down by Vitruvius (*ubi sup.*), was not to be more than three times or less than twice its width. In any cases where, from the necessity of the locality, the length exceeded these proportions, the excess was to be masked by the construction of small apartments (*chalcidica*) at the further end, on both sides of the tribunal. On each side of the central area was one, or sometimes, as in the Ulpian and Æmilian basilicas, two rows of columns. These were returned at either end, cutting off a vestibule at one extremity, and the tribunal or court proper, forming a kind of transept,

elevated above the nave, at the other. Above the aisles thus formed (*porticus*) were galleries, formed by a second row of columns supporting the roof, approached by external staircases, for the accommodation of the general public—men on one side, women on the other (Plin., *Epist.*, vi. 33). They were guarded by a parapet wall (*pluteus*) between the columns, high enough to prevent those in the galleries from being seen by those below. Sometimes, as in Vitruvius's own basilica at Fanum, and in that at Pompeii, instead of a double there was only a single row of columns, the whole height of the building, on which the roof rested. In this case the galleries were supported by square piers (*parastatæ*) behind the main columns. The building was lighted with windows in the side walls, and at the back of the galleries. In the centre of the end-wall were the seats of the judge and his assessors, generally occupying a semicircular apse, the prætor's curule chair standing in the centre of the curve. When the assessors were very numerous (according to Pliny, *u.s.*, they sometimes amounted to one hundred and eighty), they sat in two or three concentric curves arranged like the seats of a theatre. The advocates and other officials filled the rest of the raised platform, divided from the rest of the building by a screen of lattice-work (*cancelli*). In the centre of the chord of the apse stood an altar on which the *judices* took an oath to administer true justice. The tribunal sometimes ended square instead of apsidally. This is so in the basilica at Pompeii (see the plan annexed), where the tribunal is parted from the body of the hall by a *podium* bearing a screen of six columns, and is flanked by staircases to the galleries and by the *chalcidica*. The larger and more magnificent basilicas were sometimes finished with an apse at each extremity.

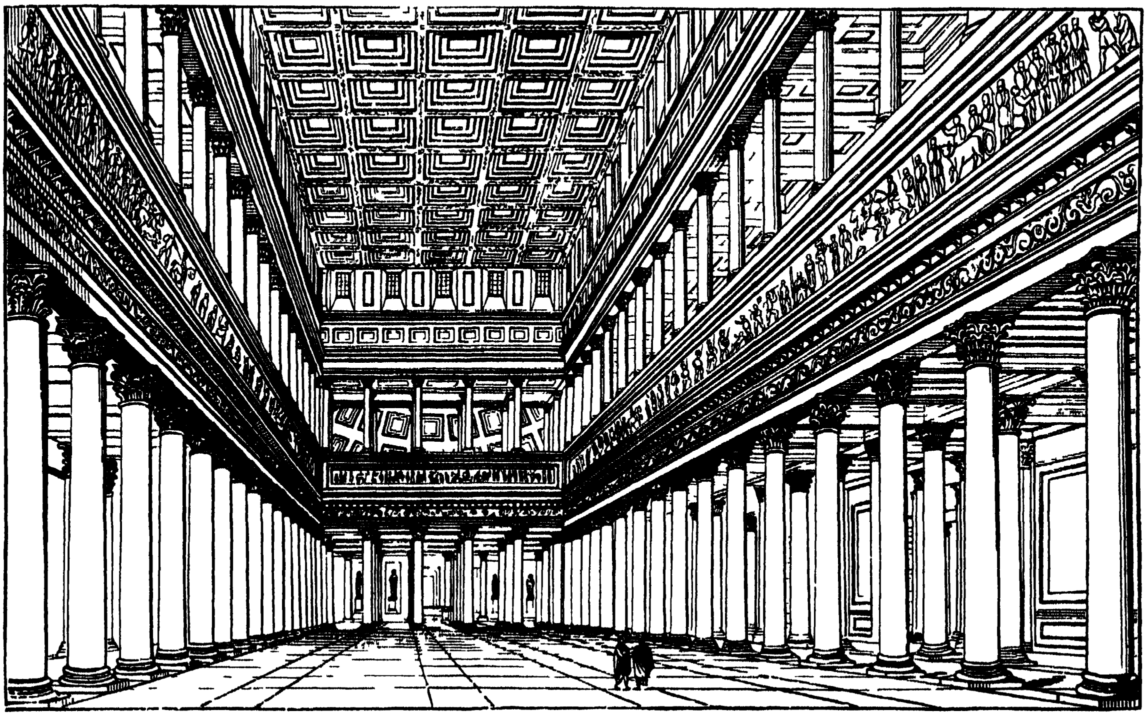

FIG. 2.—Interior view of Trajan's Basilica (*Basilica Ulpia*), as restored by Canina.

The plans of Trajan's basilica usually give this arrangement. The fragment of the ground-plan in the marble tablets preserved in the Capitol, usually called that of the Æmilian, but really, as Canina has shown, that of the Ulpian basilica, also shows an apse, designated (*Atrium*) *Libertatis*. This, we know from many ancient authorities, was the locality

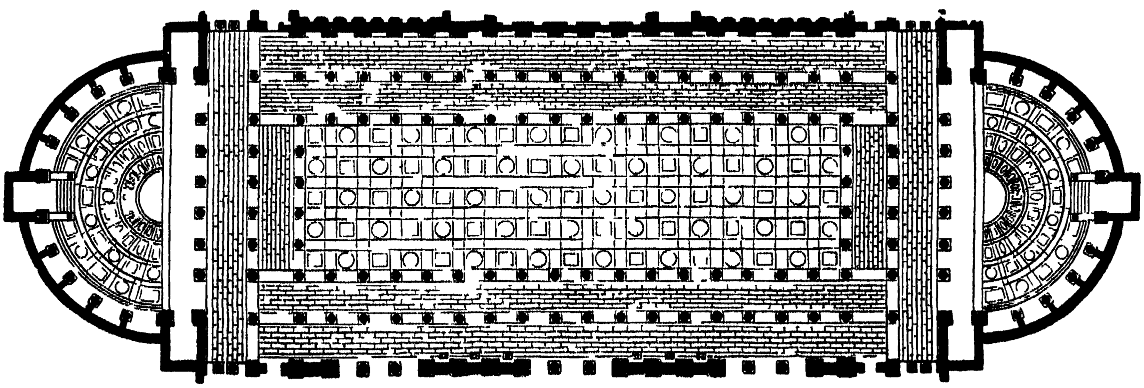

FIG. 3.—Ground-Plan of Trajan's Basilica (*Basilica Ulpia*).

for the manumission of slaves; and, therefore, the tribunal must have been at the other end, and, doubtless, also apsidal. The basilica of Trajan was one of the largest and most magnificent in Rome. From its existing remains we learn that it was 174 feet in breadth, and more than twice as long as it was broad. (The plan and supposed internal arrangements will be seen in the annexed woodcuts from Canina.) The nave, 86 feet in breadth, was divided from

the double aisles by rows of granite columns, 35 feet high. An upper row of columns in front of the galleries above the aisles supported a ceiling, covered with plates of gilt bronze. The total internal height was about 120 feet. The walls were cased with white marble from Luna. It was paved with giallo antico and purple breccia. A side court, which enclosed the well-known memorial column to Trajan, was flanked by libraries, *Bibliotheca Græca* and *Latina* (Sidon. Apollinaris, *Epigr.*, ix. 16).

FIG. 4.—Section of the Basilica of Constantine or Maxentius (Temple of Peace).

The basilica of Maxentius (or of Constantine), usually known as the *Temple of Peace*, in the Forum at Rome, was on an entirely different plan from those already described. The internal colonnades were dispensed with, the central space being covered by a vast quadripartite brick vault, in three bays; and the aisles were roofed with three huge barrel vaults, each 72 feet in span. Columns were only used for ornament. The tribunal was apsidal. Its width was 195 feet, but it was 100 feet shorter than Trajan's basilica. The ground-plan of a small but interesting basilica, of which the foundations remain at Otricoli (Ocriculum), is given by Agincourt (pl. lxxiii. No. 100). The nave is of four bays; beyond the aisles there is an additional aisle of annexed buildings or *chalcidica;* the apse is internal. A good example of a provincial basilica remains at Trèves. It is a plain hall, about 90 feet long, the walls being 100 feet high, without aisles, and it has an apsidal tribunal elevated considerably above the floor. Under the empire, when architectural magnificence reached an hitherto unparalleled height, *basilicæ* formed a part of the plan of the palaces erected by the emperors and nobles of Rome (Vitruv., vi. 81). A beautiful example on a small scale, the *Basilica Jovis*, has been recently excavated in the ruins of the palace of the Cæsars on the Palatine. Only the lower part of the walls remains, but the arrangements of the building are singularly perfect, even to the pierced marble *cancelli*, and throw the clearest light on the construction of these halls.

On the establishment of Christianity as the imperial religion, these vast halls furnished exactly what was wanted for the religious assemblies of the Christian community. The basilica was, in fact, a ready-made church, singularly adapted for its new purpose. The capacious nave accommodated the ordinary congregations, the galleries or aisles the females and the more dignified worshippers; while the raised tribunal formed the *bema*, or sanctuary, separated by lattice-work from the less sacred portion below, the bishop and his clergy occupying the semicircular apsis. The prætor's curule chair became the episcopal throne, the curved bench of his assessors the seat for the presbyters of the church. The inferior clergy, readers, and singers took the place of the advocates below the tribunal; while on the site of the heathen altar rose the holy table of the Eucharistic feast, divided from the nave by its protecting lattice-work screen, from which were suspended curtains guarding the sacred mysteries from the intrusive gaze of the profane.

The words of Ausonius to the Emperor Gratian, in which he speaks of "the basilicas once full of business but now of prayers for the emperor's preservation" (*Grat. Actio pro Consulatu*), are a testimony to the general conversion of these civil basilicas into Christian churches. We know this to have been the case with the basilicas of St Cross (S. Croce in Gerusalemme) and St Mary Major's at Rome, which were halls in the Sessorian and Liberian palaces respectively, granted by Constantine to the Christians. We may adduce also as evidence of the same practice a passage from the theological romance known as *The Recognitions of Clement* (bk. x. ch. 71), probably dating from the early half of the 3d century, in which we are told that Theophilus of Antioch, on his conversion by St Peter, made over "the basilica of his house" for a church. But however this may have been, with, perhaps, the single exception of St Cross, the existing Christian basilicas were erected from the ground for their sacred purpose. At Rome the columns, friezes, and other materials of the desecrated temples and public buildings furnished abundant materials for their construction. The decadence of art is plainly shown by the absence of rudimentary architectural knowledge in these reconstructions. Not only are columns of various heights and diameters made to do duty in the same colonnade, but even different orders stand side by side—(*e.g.*, Ionic, Corinthian, and Composite at St Mary's in the Trastevere); while pilasters assume a horizontal position, and serve as entablatures, as at St Lawrence's. There being no such quarry of ready-worked materials at Ravenna, the noble basilicas of that city are free from these defects, and exhibit greater unity of design and harmony of proportions. In all cases, however, the type of the civil basilica, which had proved so suitable for the requirements of Christian congregations, was adhered to with remarkable uniformity.

An early Christian basilica may be thus described in its main features:—A porch supported on pillars (as at St Clement) gave admission into an open court or *atrium*, surrounded by a colonnaded cloister (St Clement, Old St Peter's, St Ambrose at Milan, Parenzo). In the centre of the court stood a cistern or fountain (*cantharus*, *phiale*), for drinking and ablutions. In close contiguity to the atrium, often to the west, was the baptistery, usually octagonal (Parenzo). The church was entered through a long narrow porch (*narthex*), beyond which penitents, or those under ecclesiastical censure, were forbidden to pass. The narthex was sometimes internal (St Agnes), sometimes an external portico (St Lawrence's, St Paul's). Three or four lofty doorways, according to the number of the aisles, set in marble cases, gave admission to the church. The doors themselves were of rich wood, elaborately carved with scriptural subjects, or of bronze similarly adorned and often gilt. Magnificent curtains, frequently embroidered with sacred figures or scenes, closed the entrance, keeping out the heat of summer and the cold of winter.

The interior consisted of a long and wide nave, often 80 feet across, terminating in a semicircular apse, with one or sometimes (St Paul's, Old St Peter's, St John Lateran) two aisles on each side, separated by colonnades of marble pillars supporting horizontal entablatures (Old St Peter's, St Mary Major's, St Lawrence's) or arches (St Paul's, St Agnes, St Clement, the two basilicas of St Apollinaris at Ravenna). Above the pillars the clerestory wall rose to a great height, pierced in its upper part by a range of plain round-headed windows. The space between the windows and the colonnade (the later triforium-space) was usually decorated with a series of mosaic pictures in panels (Old St Peter's, St Paul's, St Mary Major's, St Apollinaris within the walls at Ravenna). The upper galleries of the secular basilicas were not usually adopted in the West, but we have examples of this arrangement at St Agnes, St Lawrence's, and the Quattro Santi Coronati. They are much more frequent in the East. The colonnades sometimes extended quite to the end of

the church (St Mary Major's), sometimes ceased some little distance from the end, thus forming a transverse aisle or transept (St Paul's, Old St Peter's, St John Lateran). Where this transept occurred it was divided from the nave by a wide arch, the western face and soffit of which were richly decorated with mosaics. Over the crown of the arch we often find a bust of Christ or the holy lamb lying upon the altar, and, on either side, the evangelistic symbols, the seven candlesticks, and the twenty-four elders. Another arch spanned the semicircular apse, in which the church always terminated. This was designated the *arch of triumph*, from the mosaics that decorated it representing the triumph of the Saviour and His church. The conch or semi-dome that covered the apse was always covered with mosaic pictures on a gold ground, usually paintings of our Lord, either seated or standing, with St Peter and St Paul, and other apostles and saints, on either hand. The beams of the roof were generally concealed by a flat ceiling, richly carved and gilt. The altar, standing in the centre of the chord of the apse on a raised platform, reached by flights of steps, was rendered conspicuous by a lofty canopy supported by marble pillars (*ciborium*, *baldacchino*), from which depended curtains of the richest materials. Beneath the altar was the *confessio*, a subterranean chapel, containing the body of the patron saint, and relics of other holy persons. This was approached by descending flights of steps from the nave or aisles. The *confessio* in some cases reproduced the original place of interment of the patron saint, either in a catacomb-chapel or in an ordinary grave, and thus formed the sacred nucleus round which the church arose. We have good examples of this arrangement at St Peter's, St Paul's, St Pudenziana, and St Lawrence. It was copied, as we will see hereafter, in the original cathedral of Canterbury. The bishop or officiating presbyter advanced from his seat in the centre of the semicircle of the apse to the eastern side (ritually) of the altar, and celebrated the Eucharist with his face to the congregation below. At the foot of the altar steps a raised platform occupying the upper portion of the nave formed a choir for the singers, readers, and other inferior clergy. This oblong space was separated from the aisles and from the western portion of the nave by low marble walls or railings. From these walls projected *ambones*, or pulpits with desks, also of marble, ascended by steps. That for the reader of the gospel was usually octagonal, with a double flight of steps westward and eastward. That for the reader of the epistle was square or oblong.

The exterior of the basilicas was usually of a repulsive plainness. The vast brick walls were unrelieved by orna-

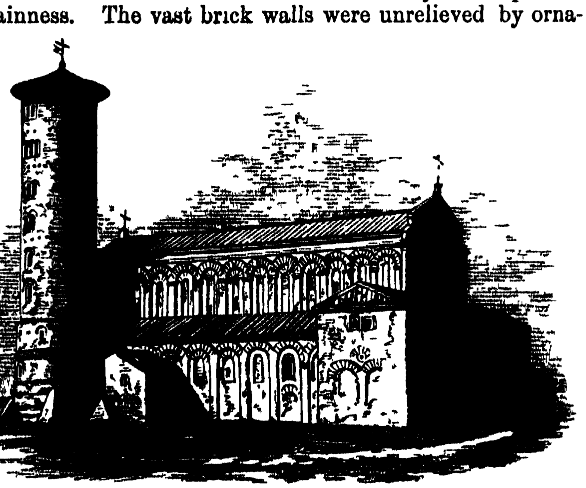

FIG. 5.—Exterior view of St Apollinaris in Classe, Ravenna.

ment, without any compensating grace of outline or beauty of proportion. An exception was made for the west front, which was usually covered with plates of marble mosaics or painted stucco (Old St Peter's, St Lawrence's). This part was frequently crowned with a hollow projecting cornice (St Lawrence's, Ara Cœli). But in spite of any decorations the external effect of a basilica must always have been heavy and unattractive. The annexed view of St Apollinaris in Classe at Ravenna affords a typical example.

To pass from general description to individual churches, the first place must be given, as the earliest and grandest examples of the type, to the world-famous Roman basilicas; those of St Peter, St Paul, and St John Lateran, "*omnium urbis et orbis ecclesiarum mater et caput.*" It is true that no one of these exists in its original form, Old St Peter's having been entirely removed in the 16th century to make room for its magnificent successor; and both St Paul's and St John Lateran having been greatly injured by fire, and the last named being so completely modernized as to have

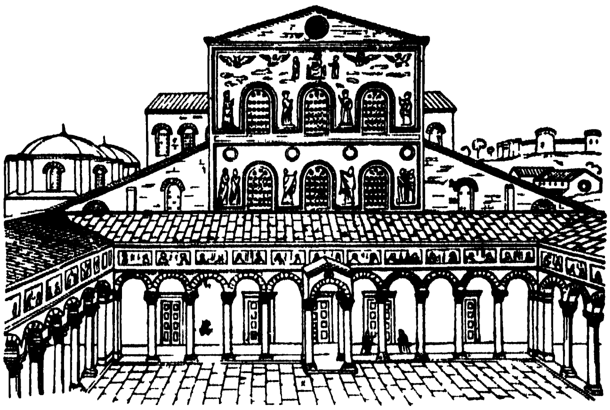

FIG. 6.—Façade of old St Peter's, Rome.

lost all interest. Of the two former, however, we possess drawings, and plans, and minute descriptions, which give an accurate conception of the original buildings. To commence with St Peter's, from the woodcuts annexed it will be seen that the church was entered through a vast colonnaded *atrium*, 212 feet by 235 feet, with a fountain in the centre,—the atrium being preceded by a porch mounted by a noble flight of steps. The church was 212 feet wide by 380 feet long; the nave, 80 feet in width, was six steps lower than the side aisles, of which there were two on each side. The four dividing colonnades were each of twenty-two Corinthian columns. Those next the nave supported horizontal entablatures. The inner colonnades bore arches, with a second clerestory. The main clerestory walls were divided into two rows of square panels

containing mosaics, and had windows above. The transept projected beyond the body of the church,—a very unusual arrangement. The apse, of remarkably small dimensions, was screened off by a double row of twelve wreathed columns of Parian marble, of great antiquity, reported

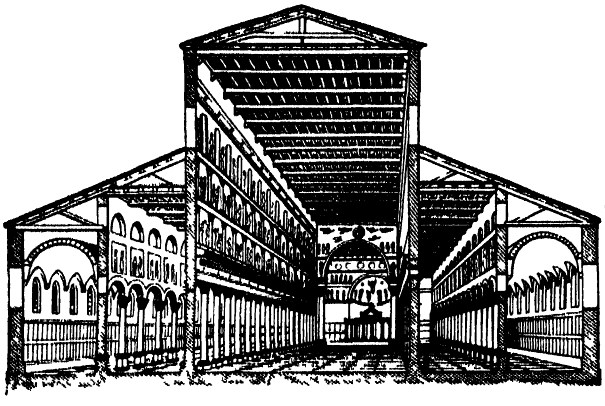

FIG. 8.—Sectional view of the old Basilica of St Peter, before its destruction in the 15th century.

to have been brought from Greece, or from Solomon's Temple. The pontifical chair was placed in the centre of the curve of the apse, on a platform raised several steps above the presbytery. To the right and left the seats of the cardinals followed the line of the apse. At the centre of the chord stood the high altar beneath a ciborium, resting on four pillars of porphyry. Beneath the altar was the subterranean chapel, the centre of the devotion of so large a portion of the Christian world, believed to contain the remains of St Peter; a vaulted crypt ran round the foundation wall of the apse in which many of the popes were buried. The roof showed its naked beams and rafters.

The basilica of St Paul without the walls, dedicated 324 A.D., rebuilt 388–423, remained in a sadly neglected state, but substantially unaltered, till the disastrous fire of 1823, which reduced the nave to a calcined ruin. Its plan and dimensions were almost identical with those of St Peter's, as will be seen from the annexed woodcuts. Its double aisles were formed by four colonnades, each of twenty Corinthian pillars, 33 feet high, all supporting arches. Of these pillars twenty-four were of the best period of Roman art, taken from the mausoleum of Augustus, or from the basilica Æmilia. The contrast between them and those of the 5th century, standing side by side with them, shows how greatly art had declined. As at St Peter's, the walls above the arches were lined with a double row of mosaic panels, below which was a band of circles containing portraits of the popes, from St Peter downwards. The transept was parted from the nave by a solid wall, with openings pierced in it, and in later times was divided down the middle by a transverse colonnade. The high altar rose above a crypt, or *confessio*, traditionally believed to be the catacomb of Lucina, a noble Roman Christian matron, to which the body of the apostle Paul had been removed 251 A.D. The narthex was external. St Paul's had completely lost its atrium. The bronze doors, covered with scriptural reliefs, had been brought from Constantinople.

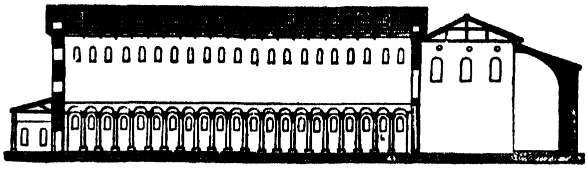

FIG. 10.—Section of the Basilica of St Paul, Rome.

The only parts of the modernized five-aisled basilica of St John Lateran (of which we have a plan in its original state, Agincourt, pl. lxxiii. No. 22) which retain any interest, are the double vaulted aisle which runs round the apse, a most unusual arrangement, and the baptistery. The latter is an octagonal building standing some little distance from the basilica to the south. Its roof is supported by a double range of columns, one above the other, encircling the baptismal basin sunk below the floor.

Of the three-aisled basilicas the best example is the Liberian or St Mary Major's, dedicated 365, and reconstructed 432 A.D. Its internal length to the chord of the apse is 250 feet, by 100 feet in breadth. The Ionic pillars of grey granite, uniform in style, twenty on each side, form a colonnade of great dignity and beauty, unfortunately broken towards the east by intrusive arches opening into chapels. The clerestory, though modern, is excellent in style and arrangement. Corinthian pilasters divide the windows, beneath which are very remarkable mosaic pictures of subjects from Old Testament history, generally supposed to date from the pontificate of Sixtus III., 432–440. The face of the arch of triumph presents also a series of mosaics illustrative of the infancy of our Lord, of great value in the history of art. The apse is of later date, reconstructed by Paschal I. in 818.

The Sessorian basilica, now St Cross (Santa Croce in Gerusalemme), is of exceptional arrangement. Originally a hall of the palace known as *Sessorium*, it was granted by Constantine for the purposes of Christian worship, and a vast apse, nearly the whole breadth of the hall, was added at the east end. The side walls are pierced by two tiers of large arched openings, originally communicating with a second range of aisles. Of these the lower range has been built up, but the upper is still open, forming immense windows.

Among the remaining basilicas of Rome those of St Lawrence (S. Lorenzo fuori le Mura) and St Agnes deserve special mention, as exhibiting a gallery corresponding to those of the civil basilicas and to the later triforium, carried above the aisles and returned across the west end. The architectural history of St Lawrence's is curious. When originally constructed, 578–590, it consisted of a short nave of six bays, with an internal narthex the whole height of the building. In the 13th century Honorius III. disorientated the church, by pulling down the apse, and erecting a nave of twelve bays on its site and beyond it, thus converting the original nave into a square-ended choir, the level being much raised, and the magnificent Corinthian columns half buried. As a consequence of the church being thus shifted completely round, the face of the arch of triumph, turned away from the present entrance, but towards the original one, is invested with the usual mosaics (Agincourt, pl. xxviii. Nos. 29, 30, 31). The basilica of St Agnes, 625–638, of which we give a plan and section, is a small but interesting building, much like what St Lawrence's must have been before it was altered. From

the fall of the ground the upper galleries are on a level with the road at the east end, and were originally entered from it. St Cross originally had similar galleries above the arcade.

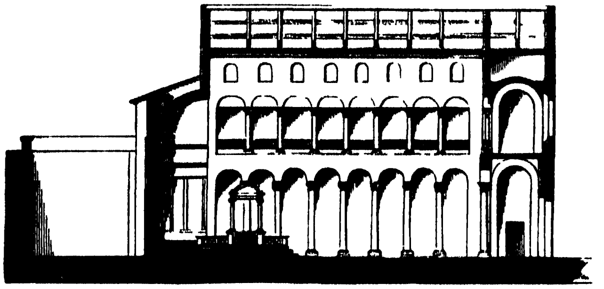

FIG. 12.—Section of Basilica of St Agnes at Rome.

Though inferior in size, and later in date than most of the basilicas already mentioned, that of St Clement is not surpassed in interest by any one of them. This is due to its having retained its original ritual arrangements and church-fittings more perfectly than any other. These fittings have been removed from the earlier church, lying below the existing building, which at some unknown date and for some unrecorded reason, was abandoned, filled up with earth, and a new building erected upon it as a foundation. The most probable account is that the earlier church was so completely overwhelmed in the ruin of the city in 1084, when Robert Guiscard burnt all the public buildings from the Lateran to the Capitol, that it was found simpler and more convenient to build a new edifice at a higher level, than to repair the old one. The annexed plan and view show the peculiarities of the existing building. The church is preceded by an *atrium*, the only perfect example remaining in Rome, in the centre of which is the *cantharus*, or fountain for ablutions. The atrium is entered by a portico made up of earlier fragments very carelessly put together. The *chorus cantorum*, which occupies about one-third of the nave, is enclosed by a low marble screen, about 3 feet high, a work of the 9th century, preserved from the old church, but newly arranged. The white marble slabs are covered with patterns in low relief, and are decorated with ribbons of glass mosaic of the 13th century. These screen-walls stand quite free of the pillars, leaving a passage between. On the ritual north stands the gospel-ambo, of octagonal form, with a double flight of steps westwards and eastwards. To the west of it stands the great Paschal candlestick, with a spiral shaft, decorated with mosaic. Opposite, to the south, is the epistle-ambo, square in plan, with two marble reading-desks facing east and west, for the reading of the epistle and the gradual respectively. The sanctuary is raised two steps above the choir, from which it is divided by another portion of the same marble screen. The altar stands beneath a lofty *ciborium*, supported by marble columns, with a canopy on smaller shafts above. It retains the rods and rings for the curtains to run on. Behind the altar, in the centre of the curved line of the apse, is a marble episcopal throne, bearing the monogram of Anastasius who was titular cardinal of this church in 1108. The conch of the apse is inlaid with mosaics of quite the end of the 13th century. The subterranean church, disinterred by the zeal of Father Mullooly, the prior of the adjacent Irish Dominican convent, is supported by columns of very rich marble of various kinds. The aisle walls, as well as those of the narthex, are covered with fresco-paintings, of various dates from the 7th to the 11th century, in a marvellous state of preservation. (See *St Clement, Pope and Martyr, and his Basilica in Rome*, by Joseph Mullooly, O.P., Rome, 1873.)

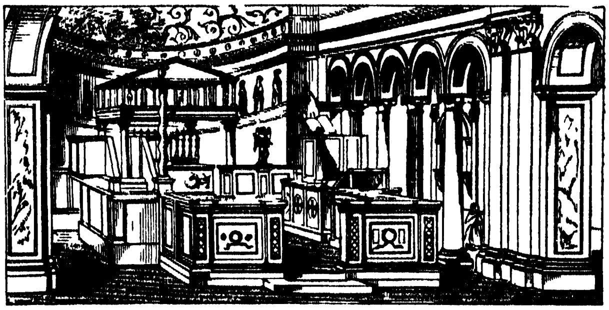

FIG. 14.—Interior of St Clement, Rome.

Out of Rome the most remarkable basilican churches are the two dedicated to St Apollinaris at Ravenna. They are of smaller dimensions than those of Rome, but the design and proportions are better. The cathedral of this city, a noble basilica with double aisles, erected by Archbishop Ursus, 400 A.D. (Agincourt, pl. xxiii. No. 21), was unfortunately destroyed on the erection of the present tasteless building. Of the two basilicas of St Apollinaris, the earlier, S. Apollinare Nuovo, originally an Arian church erected by Theodoric, 493–525, measuring 315 feet in length by 115 feet in breadth, has a nave 51 feet wide, separated from the single aisles by colonnades of twenty-two pillars, supporting arches, a small prismatic block bearing a sculptured cross intervening with very happy effect between the capital and the arch. The clerestory wall is not stilted to the excessive height of the Roman examples. Below the windows a continuous band of saintly

figures, male on one side and female on the other, advancing in stately procession towards Our Lord and the Virgin Mother respectively, affords one of the most beautiful examples of mosaic ornamentation to be found in any church. The design of the somewhat later and smaller church of St Apollinaris in Classe, 538–549 A.D., measuring 216 feet by 104 feet, is so similar that they must have proceeded from the same architect (Agincourt, pl. lxxiii., No. 35).

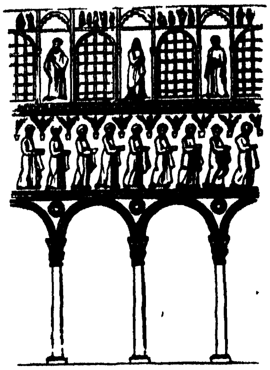

FIG. 15.—Arches of St Apollinare Nuovo, Ravenna.

The cathedral on the island of Torcello near Venice, originally built in the 7th century, but largely repaired *circa* 1000 A.D., deserves special attention from the fact that it preserves, in a more perfect state than can be seen elsewhere, the arrangements of the seats in the apse. The bishop's throne occupies the centre of the arc, approached by a steep flight of steps. Six rows of stone benches for the presbyters, rising one above another like the seats in a theatre, follow the curve on either side,—the whole being singularly plain and almost rude. The altar stands on a

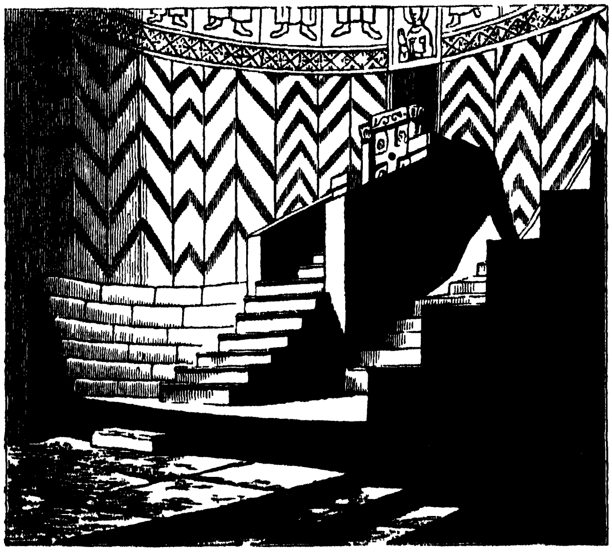

FIG. 16.—Apse of Basilica, Torcello, with Bishop's throne and seats for the clergy. From a drawing by the late Lady Palgrave.

platform; the sanctuary is divided from the nave by a screen of six pillars. The walls of the apse are inlaid with plates of marble. The church is 125 feet by 75 feet. The narrow aisles are only 7 feet in width.

Another very remarkable basilica, less known than it deserves to be, is that of Parenzo in Istria, *circa* 512 A.D. Few basilicas have sustained so little alteration. From the annexed ground-plan it will be seen that it retains its *atrium*, and a baptistery, square without, octagonal within, to the west of it. Nine pillars divide each aisle from the nave, some of them borrowed from earlier buildings. The capitals are Byzantine. The choir occupies the three easternmost bays. The apse, as at Torcello, retains the bishop's throne and the bench for the presbyters apparently unaltered. The mosaics are singularly gorgeous, and the apse walls, as at Torcello, are inlaid with rich marble and mother-of-pearl. The dimensions are small,—121 feet by 32 feet. (See *Kunstdenkmale des Oesterreichischen Kaiserstadts*, by Dr G. Heider and others.)

In the Eastern church, though the erection of St Sophia at Constantinople introduced a new type which almost

entirely superseded the old one, the basilican form, or as it was then termed *dromical*, from its shape being that of a race-course (*dromos*), was originally as much the rule as in the West. The earliest church of which we have any clear account, that of Paulinus at Tyre, 313–322 A.D., described by Eusebius (*H. E.*, x. 4, § 37), was evidently basilican, with galleries over the aisles, and had an atrium in front. That erected by Constantine at Jerusalem, on the site of the Holy Sepulchre, 333, followed the same plan (Euseb., *Vit. Const.*, iii. c. 29), as did the original churches of St Sophia and of the Apostles at Constantinople. Both these buildings have entirely passed away, but we have an excellent example of an Oriental basilica of the same date still standing in the church of the Nativity at Bethlehem, rebuilt by Justinian in the 6th century. Here we find an oblong atrium, a vestibule or narthex, double aisles with Corinthian columns, and a transept, each end of which terminates in apse, in addition to that in the usual position. Beneath the centre of the transept is the subterranean church of the Nativity (De Vogüé, *Les Eglises de la Terre Sainte*, p. 46).

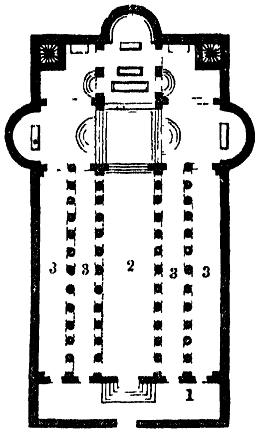

FIG. 18.—Plan of church of the Nativity, Bethlehem.

1 Narthex. 2. Nave. 3, 3 Aisles.

Constantinople still preserves a basilican church of the 5th century, that of St John Studios, 463, now a mosque. It has a nave and side aisles divided by columns supporting a horizontal entablature, with another order supporting arches forming a gallery above. There is the usual apsidal termination. The chief difference between the Eastern and Roman basilicas is in the magnitude of the galleries. This is a characteristic feature of Eastern churches, the galleries being intended for women, for whom privacy was more studied than in the West (Salzenberg, *Altchrist. Baudenkmale von Constantinople*).

Other basilican churches in the East which deserve notice are those of the monastery of St Catherine on Mount Sinai built by Justinian, that of Dana between Antioch and Bir of the same date, St Philip at Athens, Bosrah in Arabia, Xanthus in Lycia, and the very noble church of St Demetrius at Thessalonica. Views and descriptions of most of these may be found in Texier and Pullan's *Byzantine Architecture*, Couchaud's *Choix d'Eglises Byzantines*, and the works of the count de Vogüé. We may refer to Fergusson's *History of Architecture* for views and plans and description of the very interesting early miniature Christian basilicas, some of which are probably the earliest existing Christian buildings in the Mediterranean provinces of Africa. The same work (p. 640) also gives an account of the early French basilica, dating from the

6th or 7th century, known as the *Basse Œuvre* at Beauvais; as well as (pp. 550–552) of those belonging to the 8th or 9th century, in the neighbourhood of the Lake of Constance at Reichenau and Romain Motier, and at Granson on the Lake of Neufchatel.

The first church built in England under Roman influence was the original Saxon cathedral of Canterbury. From the annexed ground-plan, as conjecturally restored by Professor

Willis from Eadmer's description, we see that it was an aisled basilica, with an apse at either end, containing altars standing on raised platforms approached by steps. Beneath the eastern platform was a crypt, or *confessio*, containing relics, "fabricated in the likeness of the confessionary of St Peter at Rome" (Eadmer). The western apse, dedicated to the Blessed Virgin, contained the bishop's throne. From this and other indications Willis thinks that this was the original altar end, the eastern apse being a subsequent addition of Archbishop Odo, *circa* 950, the church having been thus turned from west to east, as at the already-described basilica of St Lawrence at Rome. The choir, as at St Clement's, occupied the eastern part of the nave, and like it was probably enclosed by breast-high partitions. There were attached towers to the north and south of the nave. The main entrance of the church was under that to the south. At this *suthdure*, according to Eadmer, "all disputes from the whole kingdom, which could not legally be referred to the king's court, or to the hundreds and counties, received judgment." The northern tower contained a school for the younger clergy.

There remains one other English basilican church to be mentioned, that of Brixworth in Northamptonshire, probably erected by Saxulphus, abbot of Peterborough, *circa* 690 A.D. It consisted of a nave divided from its aisles by quadrangular piers supporting arches turned in Roman brick, with small clerestory windows above, a short chancel terminating in an apse, outside which, as at St Peter's at Rome, ran a circumscribing crypt entered by steps from the chancel. At the west end was a square tower, the lower story of which formed a porch.

(E. V.)

BASILICA, a code of law, drawn up in the Greek language, with a view to put an end to the uncertainty which prevailed throughout the empire of the East in the 9th century as to the authorized sources of law. This uncertainty had been brought about by the conflicting opinions of the jurists of the 6th century as to the proper interpretation to be given to the legislation of the Emperor Justinian, from which had resulted a system of teaching which had deprived that legislation of all authority, and the imperial judges at last were at a loss to know by what rules of law they were to regulate their decisions. An endeavour had been made by the Emperor Leo the Isaurian to remedy this evil, but his attempted reform of the law had been rather calculated to increase its uncertainty; and it was reserved for Basilius the Macedonian to show himself worthy of the throne, which he had usurped, by purifying the administration of justice and once more reducing the law into an intelligible code. There has been considerable controversy as to the part which the Emperor Basilius took in framing the new code. There is, however, no doubt that he abrogated in a formal manner the ancient laws, which had fallen into desuetude, and the more probable opinion would seem to be, that he caused a revision to be made of the ancient laws which were to continue in force, and divided them into forty books, and that this code of laws was subsequently enlarged and distributed into sixty books by his son Leo the Philosopher. A further revision of this code is stated to have been made by Constantinus Porphyrogenitus, the son and successor of Leo, but this statement rests only on the authority of Theodorus Balsamon, a very learned canonist of the 12th century, who, in his preface to the *Nomocanon* of Patriarch Photius, cites passages from the Basilica, which differ from the text of the code as revised by the Emperor Leo. The weight of authority, however, is against any further revision of the code having been made after the formal revision which it underwent in the reign of the Emperor Leo, who appointed a commission of jurists under the presidency of Sympathius, the captain of the body-guard, to revise the work of his father, to which he makes allusion in the first of his *Novellæ*. This latter conclusion is the more probable from the circumstance, that the text of the code, as revised by the Emperor Leo, agrees with the citations from the Basilica which occur in the works of Michael Psellus and Michael Attalates, both of them high dignitaries of the court of Constantinople, who lived a century before Balsamon, and who are silent as to any second revision of the code having taken place in the reign of Constantinus Porphyrogenitus, as well as with other citations from the Basilica, which are found in the writings of Mathæus Blastares and of Constantinus Hermenopulos, both of whom wrote shortly after Balsamon, and the latter of whom was far too learned a jurist and too accurate a lawyer to cite any but the official text of the code.

Authors are not agreed as to the origin of the term Basilica, by which the code of the Emperor Leo is now distinguished. The code itself appears to have been originally entitled *The Revision of the Ancient Laws* (ἡ ἀνακάθαρσις τῶν παλαιῶν νόμων); next there came into use the title ἡ ἑξηκοντάβιβλος, derived from the division of the work into sixty books; and finally, before the conclusion of the 10th century, the code came to be designated ὁ βασιλικός, or τὰ βασιλικά, being elliptical forms of ὁ βασιλικὸς νόμος and τὰ βασιλικὰ νόμιμα, namely the Imperial Law or the Imperial Constitutions. This explanation of the term "Basilica" is more probable than the derivation of it from the name of the father of the Emperor Leo, inasmuch as the Byzantine jurists of the 11th and 12th centuries ignored altogether the part which the Emperor Basilius had taken in initiating the legal reforms,

which were completed by his son; besides the name of the father of the Emperor Leo was written *βασίλειος*, from which substantive, according to the genius of the ancient Greek language, the adjective *βασιλικός* could not well be derived.

No perfect MS. has been preserved of the text of the Basilica, and the existence of any portion of the code seems to have been ignored by the jurists of Western Europe, until the important bearing of it upon the study of the Roman law was brought to their attention by Viglius Zuichemus, professor of the Roman law in the university of Padua, in his preface to his edition of the Greek *Paraphrase of Theophilus*, published in 1533. A century, however, elapsed before an edition of the sixty books of the Basilica, as far as the MSS. then known to exist supplied materials, was published in seven volumes, by Carolus Annibal Fabrotus, under the patronage of Louis XIII. of France, who assigned an annual stipend of two thousand livres to the editor during its publication, and placed at his disposal the royal printing-press. This edition, although it was a great undertaking and a work of considerable merit, was a very imperfect representation of the original code. A newly restored and far more complete text of the sixty books of the Basilica has recently issued from the press of Johannes Ambrosius Barth at Leipsic, in six volumes, edited by Professor Charles William Ernest Heimbach of the university of Jena, assisted by his brother Gustavus Ernest Heimbach. This is one of the most important literary works of the 19th century. The learned editor lived long enough to witness the completion of the text of the Basilica by the publication of the fifth volume in 1850. He died in 1865, leaving behind him a valuable historical introduction to the code, and a manual of its contents, which are printed in the sixth and last volume, published at Leipsic in 1870. Several MSS., which contain portions of the code or of works bearing directly on the code, have been available for this edition, which were not accessible to Fabrotus when he published his edition in 1647. Amongst others may be mentioned—MS. Coislin 151, of the 11th century, now in the Bibliothèque Nationale in Paris, which came direct from Mount Athos into the hands of Chancellor Seguier, and which contains a general index of the contents of the sixty books of the Basilica; MS. Coislin 152, of the 13th century, also in the Bibliothèque Nationale in Paris; a Palimpsest MS. of the Holy Sepulchre (*τοῦ ἁγίου τάφου*), which was discovered in 1838 by Dr C. E. Zachariæ von Lingenthal, in the palace of the patriarch of Jerusalem in Constantinople. The text of four books of the Code has been restored by Dr C. E. Zachariæ von Lingenthal from this MS., and is printed in an appendix to the third volume of Heimbach's edition. A further MS. deserves notice, being No. 853 in the Vatican Library at Rome; it belongs to the 14th century, and is the only MS. which contains the work known as *Tipucitus*. This MS. has been very carefully collated by Gustavus Ernest Heimbach, and the text of a portion of Tipucitus has been printed from this MS. in the appendix to the second volume of Heimbach's edition, the remaining portions of the work having been incorporated by Heimbach into the text of the restored code. It may seem strange that so important a body of law as the Basilica should not have come down to us in its integrity, but a letter has been preserved, which was addressed by Mark the patriarch of Alexandria to Theodorus Balsamon, from which it appears that copies of the Basilica were in the 12th century very scarce, as the patriarch was unable to procure a copy of the work. The great bulk of the code was an obstacle to the multiplication of copies of it, whilst the necessity for them was in a great degree superseded by the publication from time to time of synopses and encheiridia of its contents, composed by the most eminent jurists, of which a very full account will be found in the *Histoire du Droit Byzantin*, by the advocate Mortreuil, published in Paris in 1846.

BASILICATA, or, as it is also called, POTENZA, a province of Italy, bounded on the N. by Capitanata, N.E. by Terra di Bari, E. by Otranto and the Gulf of Taranto, S. by Calabria Citra, S.W. by the Mediterranean, W. by Principato Citra, and N.W. by Principato Ultra. It has an area of 4120 English square miles, and is divided into the four districts of Lagonegro, Matera, Melfi, Potenza. The population in 1871 was 500,513. In the N.W. of the territory the Apennines divide into two branches, the one running eastward to Terra di Bari, and the other southward to Calabria. The principal rivers are the Bradano, Basento, Salandrella, Agri, and Sinno, all flowing into the Gulf of Taranto. The principal productions are maize, wine, linen, hemp, and tobacco; swine, goats, and sheep are numerous; and the produce of the silkworm forms a considerable branch of industry. The cotton plant thrives well on low grounds near the sea. The chief towns are Potenza, Melfi, Francavilla, Rionero, and Tursi.

BASILIDES, one of the most celebrated of the Gnostics, flourished probably about 120 A.D. Extremely little is known of his life. He is said to have been born in Syria and to have studied at Alexandria, and this is probably correct. There is, to some extent, a corresponding uncertainty with regard to the precise doctrines held by him. Of these there are two distinct expositions, the one given chiefly by Irenæus, which has been long before the world, the other contained in the *Philosophoumena* of Hippolytus, discovered in 1842. According to Irenæus, the system of Basilides strongly resembled that of Valentinus. The first principle or root of all things, was the supreme God, the unknown and unborn Father. From Him emanated in succession *νοῦς*, *λόγος*, *φρόνησις*, *σοφία*, and *δύναμις*. From the last, according to Irenæus, sprang the powers who created the first heaven; according to Clemens Alex., however, from *δύναμις* sprang *δικαιοσύνη* and *εἰρήνη*, and these seven with the Father formed the first Ogdoad, or octave of existence. From them emanated other powers, by whom the second heaven was made, and so on in succession, each system being a more shadowy type or reflex of the original ogdoad. The number of heavens was 365, whence the whole series was called Abraxas, or Abrasax, a name frequently applied to the lower deity, or even, as by Tertullian, to the supreme God. The powers of the lowest heaven, of whom the chief was called the *ἄρχων*, created the earth. This *ἄρχων* is the God of the Jews, and against Him the other powers were arrayed. To alleviate the misfortunes of the earth, the *νοῦς*, or first emanation, became incarnate and descended upon earth. The *νοῦς* as incorporeal could not suffer death; accordingly, he changed forms with Simon of Cyrene, and stood by the cross, laughing at his enemies, while Simon suffered in his place. Salvation is spiritual, pertains only to the soul; outer actions are not in themselves good or bad. That Basilides taught this doctrine of moral indifference is not perfectly clear, but Irenæus reports that his disciples acted up to it.

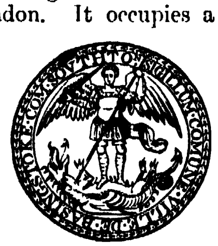
The exposition given by Hippolytus is widely different. According to the account he gives, Basilides started neither with a dualism of God and matter or evil, nor with a theory of emanation. His first principle was God, the unknown, incomprehensible, unspeakable, non-existent one, of whom nothing can be predicated, for no words are adequate to express His essence. This non-existent God, by the exercise of what may be called volition, created the *πανσπερμία*, or seed, which contained in itself the germs of all things. In this chaotic mass, which strongly resembles the *ὁμοιομερῆ* of Anaxagoras, there is a mixture of elements,—*σύγχυσις ἀρχική*,—and at the same time are embedded in it three degrees or kinds of divine sonship, consubstantial with the Deity. The first kind is refined and pure, the second gross, the third requiring purification. As all things naturally tend towards God, the first sonship ascended and sat beside the Father. The second also strove to ascend by means of the Spirit, which is to him as a wing, but he could not rise quite to the Deity, and occupied an inferior position, while the wing or spirit formed the firmament. The third sonship still remained immersed in matter. Then from the world seed there burst forth the great *ἄρχων*, or ruler, who ascended as far as the firmament, and, imagining that there was nothing beyond, glorified himself as the brightest and strongest of all beings. This ruler, who is sometimes called Abraxas, but whose true name is ineffable, produced a son wiser and better than himself, by whose aid he laid the foundations of the world. The seat of their rule is called the Ogdoad, and it extends through all the ethereal region down to the moon's sphere,

where the grosser air begins. This lower dominion is ruled by a second and inferior ἄρχων, the God of the Jews, who also had produced a son; and their seat is called the Hebdomad. Meanwhile, the third sonship, which is truly the spiritual element in the elect, is tied to matter, and is in need of deliverance. Freedom is given by the truth, *i.e.*, by a knowledge of the true system of things, and it is given by a series of illuminations. First the mind of the son of the Great Archon is enlightened, and he instructs his father, who learns with fear and repentance that there is a sphere of being higher than his own. The light then passes to the son of the Archon of the Hebdomad, who likewise instructs his father. Finally, the mind of Jesus is illuminated, and he instructs those of mankind who are able to receive the truth. There are thus three great stages in the world's religious history, each being an advance on its predecessor. These periods are the Ante-Jewish, the Jewish, and the Christian. All the souls capable of receiving the light ascend upwards, while their bodies return to the primeval chaos; the minds of all others are shrouded in eternal night, the darkness of ignorance. For the relation of Basilides to other Gnostics, and for the interpretation of his intensely symbolic expressions, see GNOSTICS.

The earlier accounts of Basilides, such as those of Neander, Baur (in the *Christliche Gnosis*), and Matter, were based for the most part on Irenæus. The discovery of the *Philosophoumena* threw unexpected light on the subject, and the later expositions generally follow Hippolytus as the exponent of the original system of Basilides. Hilgenfeld still retains the older view. Full information is to be found in Baur, *Kirchengeschichte*, i.; Lipsius, *Gnosticismus;* Uhlhorn, *Das Basilideanische System;* Mansel, *Gnostic Heresies.*

BASILISK,—βασιλίσκος of the Greeks, and Tsepha (cockatrice) of the Hebrews,—a name applied by the ancients to a horrid monster of their own imagination, to which they attributed the most malignant powers and an equally fiendish appearance. The term is now applied, owing to a certain fanciful resemblance, to a genus of Lizards belonging to the family *Iguanidæ*, the species of which are characterized by the presence of a membranous bag on the crown of the head, which they can distend or contract at will, and of a fin-like ridge along the back and part of the tail. Both appendages are admirably adapted for aiding the basilisk in swimming, while they do not impede its movements on land,—its mode of life being partly aquatic, partly arboreal. The Mitred Basilisk occurs in Guiana, the Hooded Basilisk in Amboyna.

BASINGSTOKE, a market and borough town in the county of Hants, 45 miles from London. It occupies a pleasant situation, and has a good trade in corn and malt, which has been greatly facilitated by the canal which joins the rivers Wey and Thames. The parish church, St Michael's, is a spacious and handsome structure, dating from the reign of Henry VIII. In the neighbourhood is Basing House, remarkable for its defence by the marquis of Winchester against the Parliamentary forces in 1645. Population in 1871, 5574.



Arms of Basingstoke.

BASKERVILLE, JOHN, a celebrated printer, and the introducer of many improvements in type-founding, was born at Wolverley in Worcestershire in 1706, and died in 1775. About the age of twenty he became a writing-master at Birmingham, and he seems to have had a great talent for caligraphy and carving in stone. While at Birmingham his attention was attracted to the business of japanning, which he took up with great zeal He made some important improvements in the process, and gained a considerable fortune. About the year 1750 he began to make experiments in type-founding, and soon succeeded in producing types much superior in distinctness and elegance to any that had hitherto been employed. He then set up a printing-house, and published his first work, a *Virgil* in royal quarto. *Horace*, *Terence*, *Catullus*, and others were also printed by him. These books are admirable specimens of typography; and Baskerville is deservedly ranked among the foremost of those who have advanced the art of printing. He did not print many works, as the sale did not meet his expectations; after 1765, indeed, he seems to have put forth very little. Specimens from the Baskerville press are not easily had, and are of considerable value.

BASKET, a utensil made of twigs, rushes, or strips of wood, as well as of a variety of other materials, interwoven together, and used for holding or carrying any commodity. Modern ingenuity has applied many substances before unthought of to the construction of baskets, such as iron and even glass. But wicker-work being the oldest as well as the most universal invention, it alone will be treated of in the present article. The process of interweaving twigs, seeds, or leaves, is practised among the rudest nations of the world; and as it is one of the most universal of arts, so also does it rank among the most ancient industries, being probably the origin of all the textile arts of the world. A bundle of rushes spread out may be compared to the warp of a web, and the application of others across it to the woof, also an early discovery; for basket-work is literally a web of the coarsest materials. The ancient Britons appear to have excelled in the art of basket-making, and their baskets were highly prized in Rome, as we learn from Martial (xiv. 99):—

"Barbara de pictis veni bascauda Britannis;
Sed me jam mavult dicere Roma suam."

Among many uncivilized tribes at the present day baskets of a superior order are made and applied to various useful purposes. The North American Indians prepare strong water-tight "Wattape" baskets from the roots of a species of *Abies*, and these they frequently adorn with very pretty patterns made from the dyed quills of their native porcupine, *Erethizon dorsatum.* The Indians of South America weave baskets equally useful from the fronds of the Carnahuba and other palms. The Kaffres and Hottentots of South Africa are similarly skilful in using the Ilala reed and the roots of plants; while the tribes of central Africa and the Abyssinians display great adroitness in the art of basket-weaving.

Basket-making, however, has by no means been confined to the fabrication of those simple and useful utensils from which its name is derived. Of old, the shields of soldiers were fashioned of wicker-work, either plain or covered with hides; and the like has been witnessed among modern savages. In Britain the shields of the ancient warriors, and also their huts, even up to the so-called palaces of the Saxon monarchs, were made of wicker-work; and their boats of the same material, covered with the skins of animals, attracted the notice of the Romans. Herodotus mentions boats of this kind on the Tigris and Euphrates, but with this difference, that the former seem to have been of the ordinary figure of a boat, whereas the latter were round and were covered with bitumen. Boats of this shape, about 71 feet in diameter, are used at the present day on these rivers, and boats of analogous construction are employed in crossing the rivers of India which have not a rapid current. Nothing can be more expeditious or more simple than the fabrication and materials of these vessels, if they merit that name. One may be made by six men in as many hours,—only two substances, hides and bamboo, almost always accessible, being used. Window screens, perambulators, chairs, &c., are now largely made of basket-

work, and the light pony basket carriages in general use are the representatives of the Continental Holstein waggon of the early part of the century, which was a two-horse basket carriage of considerable size. In Berlin and Kiel there now exist large factories of "Korb Mobel," devoted to the manufacture of basket-work chairs, tables, stands, frames, screens, &c., and the use of this description of furniture is very general in Continental houses.

The materials which are actually employed in the construction of basket-work are numerous and varied, and to the principal of these allusion will be made below. As it is, however, from various species of willow that the largest supply of basket-making materials is produced, we shall first confine our attention to this source. Willows for basket-work are extensively grown in Holland, Belgium, France, and Germany, whence large quantities are exported to Great Britain and even to the United States. The willows of France are highly esteemed by basket-makers as firm, clean rods; and the Dutch produce are lowest in value, being soft and pithy. No Continental rods equal those of English growth for their tough and leathery texture, and the finest of all basket-making willows are now cultivated in large quantities in the valleys of the Thames and the Trent. It was only in the early part of this century that any considerable attention was given in Britain to the cultivation of willows suitable for basket-making; and the industry was first stimulated by premiums offered by the Society for the Encouragement of Arts and Manufactures. Mr Phillips of Ely was one of the most successful early cultivators of willows, and to his exertions we owe the introduction of a valuable willow, the Brown Norfolk, *Salix triandra*. Mr Phillips's observations and experiments largely contributed to place the willow cultivation on a satisfactory commercial basis, and a similar service was rendered in Scotland by Mr Sheriffs; but the systematic maintenance of willow holts has not been continued in Scotland. One of the most successful growers of willows at the present day is Mr William Scaling of Basford, Notts, who cultivates a salictum of about 100 acres in extent. Mr Scaling has the advantage of being a practical basket-maker, and the facts which follow regarding the growth and varieties of basket-willows are chiefly gleaned from his pamphlets on willow cultivation.

The genus *Salix*, to which all willows and osiers belong, is extremely complex in its botanical characters, and the species and varieties, as systematically arranged, are very numerous. Those cultivated for basket-making Mr Scaling divides into four classes. The first class, which alone get the name of willows among basket-makers, includes the rods of six or seven different species, all of which Mr Scaling classes with *Salix fragilis*. The "willows" yield inferior basket-rods, having a tendency to throw out side-shoots which makes the rods "rough." The second class comprises the osiers, including about forty varieties used by basket-makers all grouped around the osier, *Salix viminalis*, and these form the staple of basket-making materials. In the third class, which are known in the trade as "Spaniards" or Spanish willows, are included about thirty varieties which are classed under *Salix amygdalina*. The "Spaniards" comprise some of the most useful basket-willows, the wood being more dense and elastic than is the case with osiers. The fourth class comprise the bitter willows, of which *Salix purpurea* is taken as the type, and the rods they yield are known as "whip-cord," "swallow tail," or "one-yard." These are the finest of all willows for basket-making, and owing to their bitterness they are not attacked by rabbits and hares, which frequently do much damage to all other varieties.

It was long supposed that willows flourish nowhere but with abundance of water. Undoubtedly the osier class thrive well with a considerable degree of humidity, but a dry well-drained soil is best suited for all hard-wooded varieties. For the laying out of a willow holt, Mr Scaling recommends that the land should be well drained, cleared and tilled to a depth of about one foot. Willows are propagated solely from cuttings, which retain their vitality long, and strike with great facility. The cuttings are made about 9 inches long, and two or three may be obtained from a single rod. They should be planted in rows from 16 to 18 inches apart, the plants in each row being placed at intervals of from 8 to 12 inches according to the size of the willow under cultivation; and the entire length of the cutting should be pushed into the ground. The planting may be done at any time from late autumn to early spring during the period of plant rest, when the ground is free from frost. At the end of each year the shoots are to be cut down close to the ground, manure is laid on between the rows and ploughed in, and the soil should be kept as open and free from weeds as arable land. The produce of the first year will, as a rule, be of little value; nevertheless, in Mr Scaling's opinion, it is of consequence that the rods should be cut down. The second year's crop should yield a good return; in the third year the plants are at their best, and for the ten following years they should exhibit undiminished productiveness, after which they gradually decline in strength. The entire cost of a salictum per acre Mr Scaling estimates, for the first year, at £33, 12s., and the return at £8, 12s. The outlay for the next two years he gives as £7, 5s. and £6, 15s., but the crops of these years should yield £17 and £22, just covering the cost of planting, which is the ordinary calculation of growers.

The rods intended for basket-making are either taken entire, cut from the root, split asunder, or stripped of their bark, according to the work to be produced; but in all cases they are previously soaked in water, and indeed sometimes boiled. The stripping is performed by drawing the willows through a bifurcated iron implement called a brake, which removes the bark, and the willows are then cleaned, as far as necessary, by manual operation with a knife. When they are boiled previous to peeling a very nice light brown colour is developed in the wood by the action of the tannin contained in the bark, and rods thus prepared are much more durable than those peeled white. Next they are exposed to the sun and air, and afterwards placed in a dry situation. But it is not the less necessary to preserve willows with their bark in the same manner; for nothing can be more injurious than the humidity inherent in the plant; and previous to use they must be soaked some days in water also. The barked or white osier is then divided into bundles or faggots according to size; the larger being reserved to form the strong work in the skeleton of the basket, and the smaller for weaving the bottom and sides. Should the latter be applied to ordinary work, they are taken whole; but for implements of slight and finer texture, each osier is divided into splits and skains of different degrees of size. Splits are osiers cleft into four parts, by means of an implement employed for that purpose called a cleaver, which is a wedge-shaped tool inserted at the point or top end of the rod and run down through its entire length. These are next drawn through an implement resembling the common spoke-shave, keeping the grain of the split next the iron or stock of the shave, while the pith is presented to the steel edge of the instrument, which is set in an oblique direction to the wood: and in order to bring the split into a shape still more regular, it is passed through another implement called an upright, consisting of a flat piece of steel, each end of which is fashioned into a cutting edge, like that of an ordinary chisel. The flat is bent round, so that the two edges approach each other at a greater or less interval by

means of regulating screws, and the whole is fixed into a handle. By passing the splits between the two edges they are reduced to skains, the thickness of which is determined by the interval between the edges of the tool.

The implements required by a basket-maker are few and simple. They consist, besides the preceding, of knives, bodkins, leads for keeping the work steady while in process; and where the willows are worked as rods a heavy piece of iron called a beater is employed to beat them close as they are woven in. On the Continent, where fancy baskets are made, blocks are required on which the webs of wicker-work are set to particular shapes.

An ordinary basket is made by preparing the requisite number of osiers, and preserving their length considerably greater than that of the finished work. They are ranged in pairs on the floor parallel to each other, at small intervals, in the direction of the longer diameter of the basket; and this may be called the woof,—for, as we have said, basketwork is literally a web. These parallel rods are then crossed at right angles by two of the largest osiers, with the thick ends towards the workman, who places his foot upon them; and being each woven alternately over and under the parallel pieces first laid down, they are by that means confined in their places. The whole now forms what is technically called the slath, which is the foundation of the basket. Next the long end of one of the two rods is taken and woven under and over the pairs of short ends all round the bottom, until the whole be woven in. The same is done with the other rod, and then additional long osiers are also woven in, until the bottom be of sufficient size, and the woof be occupied by them. Thus the bottom or foundation on which the superstructure is to be raised is finished; and this latter part is accomplished by sharpening the large ends of as many long and stout osiers as may be necessary to form the ribs or skeleton. These are forced or plaited, "scallumed," between the rods of the bottom from the edge towards the centre, and are turned up, "upset," in the direction of the sides; then other rods are woven in and out between each of them, until the basket is raised to the intended height, or, more correctly speaking, the depth it is to receive. The edge or brim is finished by turning down the perpendicular ends of the ribs, now protruding and standing up, over each other, whereby the whole is firmly and compactly united. A handle is adapted to the work by forcing one or more rods called bale sticks, sharpened at the end and cut to the requisite length, down the weaving of the sides, close together; and they are pinned fast, or tied by means of the rods used in twisting over the bale rods, about two inches from the brim, in order that the handle, when completed, may be retained in its proper position. The osiers are then either bound or plaited in such fashion as pleases the taste of the artist. This is the most simple kind of basket, from which others differ only in finer materials and nicer execution; but in these there is considerable scope for taste and fancy, and implements are produced of extreme neatness and ingenuity in construction. The skains are frequently smoked and dyed either of dull or brilliant colours, and by intermixing them judiciously, as also by varnishing over the colour, a very good effect is produced.

From the simplicity of this manufacture, a great many individuals, independent of professed basket-makers, are occupied in it; and it affords suitable employment to the blind in the several asylums and workshops established for their reception in this and other countries.

In addition to willows, a large variety of other materials is employed in the fabrication of wicker-work. Among the most important of these are splits of various species of bamboo, with which the Japanese and Chinese manufacture baskets of unequalled beauty and finish. The bamboo wicker-work with which the Japanese sometimes encase their delicate egg-shell porcelain is a marvellous example of manipulation, and they and the Chinese excel in the application of bamboo wicker-work to furniture. The "canes" or rattans of commerce, stems of species of *Calamus* and *Dæmonorops* are scarcely less important as a source of basket materials. In India "Cajan" baskets are extensively made from the fronds of the Palmyra palm, *Borassus flabelliformis;* and this manufacture has in recent years been established in the Black Forest of Germany, where it is now an important and characteristic staple. Among the other materials may be enumerated the odorous roots of the Khus-Khus grass, *Anatherum muricatum*, and the leaves of various species of screw pine, used in India and the East generally. The fronds of the palm of the Seychelles Islands, *Lodoicea seychellarum*, are used for very delicate basket-work in those islands. Strips of the New Zealand flax plant, *Phormium tenax*, are made into baskets in New Zealand. Esparto fibre is used in Spain and Algeria for rude fruit baskets. Various species of *Maranta* yield basket materials in the West Indies and South America; and the Tirite, a species of *Calathea*, is also similarly employed in Trinidad. Baskets are also frequently made from straw, from various sedges (*Cyperus*), and from shavings and splints of many kinds of wood.

In the basket trade special centres are recognized as the headquarters of various styles of work met in the markets. Thus Birmingham is recognized as the source of wicker perambulators; in Southport boiled willows are used, and the brown baskets for gardening and market purposes are produced, and at Castle Donnington, in Derbyshire, the flat skain work seen in fishing baskets, &c., is chiefly made. In the department of Aisne, France, the *berceaunette* or bassinet is very largely manufactured, and in Verdun much basket-work is specially prepared to suit the English market, in which the French manufacturers are able freely to compete. The Black Forest and other German manufacturers produce enormous quantities of light elegant baskets, which are largely exported. In Austria lacquered and varnished baskets are made in imitation of gold, silver, and steel, and Viennese card baskets, &c., are frequently ornamented with plaques of painted porcelain inserted in the centre.

BASNAGE, JACQUES, pastor of the Walloon Church at the Hague, was born at Rouen in Normandy on the 8th of August 1653. He was the son of Henri Basnage, one of the ablest advocates in the parliament of Normandy. At the age of seventeen, having acquired a good knowledge of the Greek and Latin authors, as well as of the English, Spanish, and Italian languages, he went to Geneva, where he began his theological studies under Mestrezat, Turretin, and Tronchin; he completed them at Sedan, under the professors Jurieu and Leblanc de Beaulieu. He then returned to Rouen, where he was received as pastor in September 1676; and in this capacity he remained till the year 1685, when, the exercise of the Protestant religion being suppressed at Rouen, he obtained leave of the king to retire to Holland. He settled at Rotterdam, and continued a minister pensionary there till 1691, when he was chosen pastor of the Walloon Church of that city. In 1709, the pensionary Heinsius secured his election as one of the pastors of the Walloon Church at the Hague, intending to employ him not only in religious but also in civil affairs. Accordingly he was engaged in a secret negotiation with Marshal d'Uxelles, plenipotentiary of France at the congress of Utrecht,—a service which he executed with so much success, that he was afterwards intrusted with several important commissions, all of which he discharged with such ability and address that Voltaire said of him that he was fitter to be a minister of state than the minister of a parish. The Abbé Dubois, who represented France at the Hague in 1716, in negotiating a defensive alliance between France, England, and the States-General, received instructions to consult with Basnage; they accordingly acted in concert, and the alliance was concluded in January 1717. His numerous published works, which are mostly in French, include—*The History of the Religion of the Reformed Churches; Jewish Antiquities; The History of the Old and New Testament; Dissertation on Duels, &c.* He died on the 22d September 1723.

BASQUE PROVINCES (*Provincias Vascongadas*). The three Spanish provinces known by this name, which are distinguished from all the other divisions of Spain by

the character, language, and manners of the inhabitants, and by the enjoyment of political privileges which make the form of their government nearly republican, are Biscay (Vizcaya), Guipuzcoa, and Alava. The territory occupied by them is in the form of a triangle, bounded on the N. by the Bay of Biscay, S. by Soria, E. by Navarra and part of France, and W. by Santander and Burgos. It comprises an area of 2958 square miles; population in 1857, 414,146. These three provinces are more particularly described under their respective heads. The French Basque provinces now form the arrondissements of Bayonne and Mauleon. The Basque language, which is also prevalent in Navarre, is still spoken by about 600,000 Spaniards and French. Its native name is *Eskuara.* It cannot be classed with any Indo-European or Semitic tongue, and appears to be of earlier origin, presenting some grammatical analogies with Mongol, North American, and certain East African languages. The forms of ordinary grammar are therefore imperfectly applicable to it. The substantive has no distinction of gender; it is made to express, by means of an extensive system of affixes, all the ordinary declensional and conjugational relations, and many which in other languages can only be expressed by periphrasis. The termination of a word may thus express together mood, tense, person, number, the case and number of the object, and also the sex, rank, and number of the individuals addressed, besides other relations. Foreign words are thus easily assimilated, but with modifications to suit the Basque ear, the latter varying according to local dialect. Diminutives and other general affixes increase the delicacy of expression, and a wide range of speech is early acquired by the natives. Compound words are readily formed by mere juxtaposition, or by elision of syllables, with peculiar modifications for euphony. The article has two forms—*a* for the singular, *ak* for the plural —affixed to the substantive. There appears to be no genuine Basque word beginning with *r*. In the usual structure of the sentences the noun, with the article affixed, occupies the first place; it is followed by the adjective, then the adverb, next the verb, and lastly the object with its prepositional affix. No written Basque is known of earlier date than the 15th century, and little genuine literature exists; the orthography is therefore arbitrary, and the earliest writings are difficult to interpret. All that has yet been noticed regarding manners, customs, institutions, and legends may be paralleled by those of other Pyrenean peoples, or traced to foreign influences. But, through their moral qualities, physical situation, and historical circumstances the Basques have built up and preserved a body of customs and institutions highly original in the mass. Each province is governed by a parliament composed of representatives selected partly by election, partly by lot, among the householders of each country parish or town. A deputation, named by the parliament, ensures the strict observance of the special laws and customs of the province, and negotiates with the representative of the Spanish Crown. Delegates from the three parliaments meet annually to consider the common interests of the provinces; they employ a seal representing three interlaced hands, with the motto *Iruracbat*, "the three are one;" but no written federal pact exists. Much speculation regarding the origin of the Basques has been indulged in without sufficient special knowledge. The belief that they originally occupied great part of Spain and Southern France, founded on the apparently Basque character of certain local names, is very generally accepted. The best introduction to all Basque questions is Bladé's *Études sur l'origine des Basques*, which sums up the literature of the subject to 1870. *Éléments de Grammaire Basque*, by L. Gèze, Bayonne, 1873, is a good practical grammar and vocabulary with exercises; the *Dictionnaire Basque Français* of Van Eyss is a particularly instructive lexicon.

BASS ROCK, an islet of greenstone and trap tuff, about a mile in circumference, on the coast of East Lothian near the entrance of the Firth of Forth, in 56° 4′ N. lat., and 2° 37′ W. long. Purchased from the Lauder family by Charles II. in 1671, it was afterwards converted into a place of confinement for state prisoners, and during the religious troubles of Scotland numbered among its captives Peden, Blackadder, and other Covenanting leaders. At the Revolution a party of King James's adherents got possession of the island, and held out after the whole of Great Britain had submitted. Dismantled of its fortifications in 1701, the Bass Rock again became private property, and is now farmed for the sake of the sea-fowls that resort thither during the breeding season. See *The Bass Rock, its Civic and Ecclesiastical History, &c.* (Edin. 1848), by M'Crie, Hugh Miller, Anderson, Fleming, and Balfour.

BASS'S STRAITS, the channel which separates Tasmania from Victoria. It is about 180 miles in length from E. to W., and about 140 from N. to S. The navigation of the strait is rendered dangerous in some parts by groups of barren islands and coral reefs scattered through it. It bears the name of Bass, the surgeon of a man-of-war, who was the first to discover, in 1798, indications of a channel between Tasmania and the neighbouring island-continent.

BASSÁHIR, a Rájput hill state in Hindustán, under the political superintendence of the Lieutenant-Governor of the Panjáb, situated between 30° 56′ and 32° 8′ N. lat., and 77° 34′ and 78° 52′ E. long. It is bounded on the N. by the Spiti valley, on the E. by Chinese Tartary, on the S. by the district of Garhwál, and on the W. by several small hill states. The aspect of the country is very hilly, and it is nowhere less than 4000 feet above sea-level. Principal rivers, the Pabur and Satlej. Estimated population, 90,000; chief towns and villages, Rampur, Chini, Songlá, and Morang. Agricultural products—wheat, opium, and Indian corn. Manufactures—blankets, shawls, and woollen cloths. Estimated gross revenue of the state, £5000 a year. Tribute paid by the chief to the British Government, £394, 10s. per annum. Estimated military force of the state, 100 men.

BASSANO, a city of Italy in the province of Vicenza. It stands on the river Brenta, over which there is a bridge 180 feet in length, built by Palladio. It is surrounded with walls, and has six gates, one of which, also by Palladio, is very much admired. In the centre of the town is the tower of Ezzelino, which now contains a library and armoury. The town contains thirty-five churches (some of them with fine paintings), several religious houses, and other public edifices. It has extensive silk-mills, besides manufactures of cloth, paper, straw hats, copper wares, &c.; and the printing establishment of S. Remondini is one of the most extensive in Italy. In 1796 Bonaparte defeated the Austrian general Wurmser in the neighbourhood, and various skirmishes took place between the two forces in 1801, 1805, 1813. Maret derived from the town his title of duke of Bassano. Population, 13,254.

BASSANO, Giacomo da Ponte, a Venetian painter, born in 1510 at Bassano. He was educated by his father, who was himself an artist, and then completed his studies at Venice. On the death of his father he returned to Bassano, and settled there. His subjects were generally peasants and villagers, cattle, and landscapes, with some portraits and historical designs. His figures are well designed, and his animals and landscapes have an agreeable air of simple nature. His compositions, though they have not much eloquence or grandeur, have abundance of force and

truth; the local colours are well observed, the carnations are fresh and brilliant, and his chiaroscuro and perspective are unexceptionable. He is said to have finished a great number of pictures, but his genuine works are somewhat rare and valuable,—many of those which are called originals being copies either by the sons of Bassano, or by others. He died in 1592, aged eighty-two. Bassano's style varied considerably during his lifetime. He naturally was at first a copier of his father, but his productions in this style are not of great value. He was then strongly attracted by the lightness and beautiful colouring of Titian, and finally adopted the style which is recognized as his own. Although he painted few great pictures, and preferred humble subjects, yet his altar-piece of the Nativity at Bassano is estimated highly by the best judges, and in Lanzi's opinion is the finest work of its class in existence.

BASSE-TERRE, the capital of St Christopher's, one of the British West India Islands. Population, 8500. See Saint Christopher's.

BASSE-TERRE, formerly the capital of Guadeloupe, one of the French West India Islands. Population, 9480. See Guadeloupe.

BASSEIN, a British district on the eastern coast of the Bay of Bengal, under the jurisdiction of the Chief Commissioner of Burmah, lies between 15° and 18° N. lat., and 94° and 96° E. long. It is bounded on the N. by the districts of Kyouk Phoo and Myanoung, on the E. by the district of Rangoon, and on the S. and W. by the Bay of Bengal. A mountain range called the Anouk-phet Toung myeng stretches through the district from north to south along the coast. The principal river of the district is the Irawadi, which debouches on the sea at its eastern extremity through a delta intersected with salt water creeks, among which the Pymalaw, Deay Pyoo, Thekadoung, and Nga Woon or Bassein River rank as important arms of the sea. Shagay-gyee and Engyay-gyee are the only two lakes in the district. The delta of the Irawadi forms, wherever cultivable, a vast sheet of rice, with cotton, sesamum, and tobacco as subsidiary crops. Bassein district has an area of 8954 square miles, of which only 351 are cultivated In 1871–72 the population amounted to 316,883, residing in 65,722 houses, and inhabiting 1554 villages, of whom 213,816, or 67 per cent., were Buddhists, 78,684 aborigines, 20,810 Christians, 2119 Mahometans, 723 Hindus, and 12 Pársís. Density of population, 34·03 per square mile. The population consisted of 31,369 agriculturists, and 285,464 non-agriculturists. Total revenue in 1870-71, £118,672, of which £36,676, or 30 per cent., was derived from land. Principal towns and villages in Bassein—(1), Bassein, population 19,577; (2), Laymyethna, 5325; (3), Pantanaw, 5876, (4), Yaygyee, 4893; (5), Nga-thainkhyoung, 3178; (6), Kang yeedaing, 1500; (7), Shweloung, 1317; (8), Myoung-mya, 1477; (9), Nga-poo-tau, 981; and (10), Kyoon-pyaw, 1655.

Bassein, the principal place of the district of the same name, situated in 16° 45′ N. lat., and 94 50′ E. long., on the eastern bank of the Bassein River, one of the main arteries by which the waters of the Irawadi discharge themselves into the sea. It forms an important seat of the rice trade, and has great capabilities both from a mercantile and a military point of view, as it commands the great outlet of the Irawadi. It fell before the British arms, in May 1852, during the second Burmese war. Since then the town population has rapidly increased, and numbered 19,577 in 1871, chiefly fishermen, craftsmen, traders, and persons connected with the rice commerce.

BASSELIN, Olivier, an old French poet or writer of verses, was born in the Val-de-Vire in Normandy about the middle of the 14th century, and died about 1418 or 1419. He was by occupation a fuller, and had a mill on the small river Vire. His songs were sprightly and joyous, and became famous. The modern Vaudevilles take their origin and name from them, and were originally called Vaux-de-Vire, *vaux* being the plural of *val*; though, according to Ménage, the word is derived from a small town Vaux near the Vire. Basselin's poems were collected and published in the 16th century by Jean le Houx, and have since been re-edited by M. Asselin in 1811, and by M. Travers in 1833. The latest edition, that by P. L. Jacob, 1858, contains some other poems in addition to those of Basselin.

BASSI, Laura Maria Caterina, an Italian lady, eminently distinguished for her learning, was born at Bologna in 1711. On account of her extraordinary attainments she received a doctor's degree, and was appointed professor in the philosophical college, where she delivered public lectures on experimental philosophy till the time of her death. She was elected member of many literary societies, and carried on an extensive correspondence with the most eminent European men of letters. She was well acquainted with classical literature, as well as with that of France and Italy. In 1738 she married Giuseppe Verrati, a physician, and left several children. She died in 1778.

BASSIANUS, Joannes, a distinguished professor in the law school of Bologna, the pupil of Bulgarus and the master of Azo. Little is known of his origin, but he is said by Carolus de Tocco to have been a native of Cremona. The most important of his writings which have been preserved is his *Summary on the Authentica*, which Savigny regards as one of the most precious works of the school of the Gloss-writers. Joannes, as he is generally termed, was remarkable for his talent in inventing ingenious forms for explaining his ideas with greater precision, and perhaps his most celebrated work is his "Law-Tree," which he entitled *Arbor Arborum*, and which has been the subject of numerous commentaries. The work represents a tree, upon the branches of which the various kinds of actions are arranged after the manner of fruit. The civil actions, or *actiones stricti juris*, being forty-eight in number, are arranged on one side, whilst the equitable or *prætorian* actions, in number one hundred and twenty-one, are arranged on the other side. A further scientific division of actions is made by him under twelve heads, and by an ingenious system of notation the student is enabled to class at once each of the civil or prætorian actions, as the case may be, under its proper head in the scientific division. By the side of the tree a few glosses were added by Joannes to explain and justify his classification. His *Lectures on the Pandects* and the *Code*, which were collected by his pupil Nicolaus Furiosus, have unfortunately perished.

BASSOON, a musical wind instrument of the reed order, made of wood, and played through a bent mouthpiece of metal. It has a compass of about three octaves, from B flat below the bass staff to C in the treble staff, and may thus be regarded as the bass instrument corresponding to the oboe and clarinet, for which see the article Oboe.

BASSO-RILIEVO. See Alto Rilievo and Relief.

BASTAR, a feudatory state in the Central Provinces of British India, situated between 20° 10′ and 17° 40′ of N. lat., and 80° 30′ and 82° 15′ of E. long., bounded on the N. by the Kanker zamíndárí and the Ráipur district; on the E. by the Bendrá Nawágarh zamíndárí and Ráipur, Jaipur state, and Sabarí River; on the S. by the Sironchá district; and on the W. by the Indrávatí River and the Aherí zamíndárí. Extreme length of the state, 170 miles; extreme breadth, 120 miles, area, estimated at 13,000 square miles. Total population, 78,856, consisting of—Hindus, 29,060; Musalmáns, 1704; aboriginal tribes of Gond origin, 48,092. Among the latter, the Máriás are a

timid, quiet, docile race, and although addicted to drinking are not quarrelsome. They inhabit the densest jungles, and are very shy, avoiding contact with strangers, and flying to the hills on the least alarm; but they bear a good character for honesty and truthfulness. They are very scantily dressed, wear a variety of trinkets, with a knife, hatchet, spear, bow and arrow, the only weapons they use. Their hair is generally shaved, excepting a topknot; and when not shaved it gets into a matted, tangled mass, gathered into a knot behind or on the crown. The Máris, a class of the Máriás, live in still denser jungles, and have little or no communication with the outside world. The Máriás and the Jhuriás are supposed to be a subdivision of the true Gond family. All the aboriginal tribes of Bastár worship the deities of the Hindu pantheon along with their own national goddess Danteswarí.

The eastern part of Bastár is a flat elevated plateau, from 1800 to 2000 feet above the level of the sea, the centre and north-west portions are very mountainous, and the southern parts are a mixture of hill and plain. On the plateau there are but few hills; the streams run slowly, and the country is a mixture of plain and undulating ground covered by dense *sál* forests. Principal mountains of the district—(1), A lofty range which separates it from the Sironchá district; (2), a range of equal height called the Belá Dilá lying in the centre of the district; (3), a range running north and south near Náráyanpur; (4), Tángrí Dongrí range, running east and west; (5). Tulsí Dongrí, bordering on the Sabarí River and the Jaipur state. There is also a small range running from the River Indravatí to the Godávarí. The Indravatí the Sabarí, and the Tál or Tálper are the chief rivers of the district; all of them affluents of the Godávarí. The soil throughout the greater portion of Bastár consists of light clay, with an admixture of sand, suited for raising rice and wet crops. Rice, sugar, and a little wheat and gram are the agricultural products of Bastár. In the jungles the Máriás and Máris rear kosrá (*Panicum italicum*) and other inferior grains. The aboriginal races generally follow the migratory system of tillage, clearing the jungle on selected patches, and after taking crops for two or three years abandoning them for new ground. Máris do not use the plough; nor do they possess buffaloes, bullocks, or cows; their only agricultural implement is a long-handled iron hoe. Lac, resin, wax galls, horns, rice a red dye called *sendri*, wild arrow-root, molasses, teak wood. and tasar-silk cocoons, are the chief staples of export. The imports, which considerably exceed the exports, consist of salt, piece-goods, brass utensils, cocoa-nuts, pepper, spices, opium, turmeric, cotton, wheat, &c. Iron-ore is found towards the eastern portion of the state, but is not much worked; gold is also found in certain places. Bastár is divided into two portions—that held by the Rájá or chief himself, and that possessed by feudatory chiefs under him. There is not a single made road within the principality. The climate of Bastár is unhealthy—fever, smallpox, dysentery, diarrhœa, and rheumatism being the prevailing diseases. Jagdalpur, Bijápur, Maddor. and Bhupálpatnam are the only places of any note in the dependency, the first-named being the residence of the Rájá and the chief people of the state. The grossest ignorance and superstition prevail, and the people live in constant fear of being bewitched or ruined by malicious magicians. The family of the Rájá of Bastár claims to be of the purest Rájput blood, and traces its origin to Warangal in the Dakhin, about the commencement of the 14th century. The revenue of Bastár is supposed to be £3610; the tribute paid by the chief to the British Government is £305, 12s.

BASTARD is a person born out of lawful wedlock, *i.e.*, whose parents have not been married previous to his birth. The rules by which legitimacy is determined vary chiefly as to the effect to be assigned to the subsequent marriage of the bastard's parents. The law of Scotland, and of most Continental countries, following the rules of the civil and canon law, legitimizes the bastard whose parents afterwards marry. The same principle was at one time advocated by the clergy in England, but summarily rejected by the famous statute of Merton (20 Hen. III. c. 9). The English law, however, takes no account of the interval between the marriage and the birth; provided the birth happens after the marriage, the offspring is legitimate. The presumption of law is in favour of the legitimacy of the child of a married woman, and at one time it was so strong that Lord Coke held that "if the husband be within the four seas, *i.e.*, within the jurisdiction of the king of England, and the wife hath issue, no proof shall be admitted to prove the child a bastard unless the husband hath an apparent impossibility of procreation." It is now settled, however, that the presumption of legitimacy may be rebutted by evidence showing non-access on the part of the husband, or any other circumstance showing that the husband could not in the course of nature have been the father of his wife's child. If the husband had access, or the access be not clearly negatived, and others at the same time were carrying on a criminal intercourse with the wife, a child born under such circumstances is legitimate. If the husband had access intercourse must be presumed, unless there is irresistible evidence to the contrary. Neither husband nor wife will be permitted to prove the non-access directly or indirectly. Children born after a divorce *a mensa et thoro* will be presumed to be bastards unless access be proved. A child born so long after the death of a husband that he could not in the ordinary course of nature have been its father is illegitimate. The period of gestation is presumed to be *about* nine calendar months; and if there were any circumstances from which an unusually long or short period of gestation could be inferred, special medical testimony would be required. A marriage between persons within the prohibited degrees of affinity was before 1835 not void, but only voidable, and the ecclesiastical courts were restrained from bastardizing the issue after the death of either of the parents. Lord Lyndhurst's Act declared all such existing marriages valid, but all future marriages between persons within the prohibited degrees of consanguinity or affinity were made null and void, and the issue illegitimate. (See MARRIAGE.) By 21 and 22 Vict. c. 93, application may be made to the Court of Divorce and Matrimonial Causes (in Scotland to the Court of Session by action of declarator) for a declaration of legitimacy and of the validity of a marriage.

The law relating to the maintenance of bastard children is governed by a considerable number of statutes passed during the present reign, the Acts of 1872 and 1873 being the last. The mother of a bastard may summon the putative father to Petty Sessions within twelve months of the birth (or at any later time if he is proved to have contributed to the child's support within twelve months after the birth), and the justices, after hearing evidence on both sides, may, if the mother's evidence be corroborated in some material particular, adjudge the man to be the putative father of the child, and order him to pay a sum not exceeding five shillings a week for its maintenance, together with a sum for expenses incidental to the birth. No such order is to be valid after the child is dead or reaches the age of thirteen, but the justices may in the order direct the payments to be continued until the child is sixteen years of age. The putative father may appeal to Quarter Sessions. Should the child afterwards become chargeable to the parish, the sum due by the father may be received by the parish officer. When a bastard child, whose mother has not obtained an order, becomes chargeable to the parish, the guardians may proceed against the putative father for a contribution. The mother of an illegitimate child is entitled to its custody in preference to the father.

The rights of a bastard are only such as he can acquire; for civilly he can *inherit* nothing, being looked upon as the son of nobody, and sometimes called *filius nullius*, sometimes *filius populi*. This, however, does not hold as to moral purposes, *e.g.*, he cannot marry his mother or bastard sister. Yet he may gain a surname by reputation though he has none by inheritance, and may even be made legitimate and capable of inheriting by the transcendent power of an Act of Parliament. All other children have their primary settlement in their father's parish; but a bastard has his in the parish where he was born, unless

such birth has been procured by fraud, or has happened under an order of removal, in a state of vagrancy, in the house of correction, or under certificate; for in law he has no father. The incapacities attaching to a bastard consist principally in this, that he cannot be heir to any one; for being *nullius filius*, he is therefore of kin to nobody, and has no ancestor from whom an inheritable blood can be derived. Therefore, if there be no other claimant upon an inheritance than such illegitimate child, it escheats to the lord. And as bastards cannot be heirs themselves, so neither can they have any heirs but those of their own bodies; for as all collateral kindred consists in being derived from the same common ancestor, and as a bastard has no legal ancestor, he can have no collateral kindred, and consequently no legal heirs, except such as claim by a lineal descent from himself. And hence, if a bastard purchase land, and die seised therefor without issue and intestate, the land escheats to the lord of the fee. Originally a bastard was deemed incapable of holy orders, and disqualified by the fact of his birth from holding any dignity in the church; but this doctrine is now obsolete, and in all other respects there is no distinction between a bastard and another man. By the law of Scotland a bastard is not only excluded from his father's succession, because the law knows no father who is not marked out by marriage; and from all heritable succession, whether by the father or mother, because he cannot be pronounced lawful heir by the inquest in terms of the brief; but also from the movable succession of his mother, because he is not her lawful child, and legitimacy is implied in all succession deferred by the law. But a bastard, although he cannot succeed *jure sanguinis*, may succeed by destination, where he is specially called to the succession by entail or testament. In Scotland, as in England, a bastard can have no legal heirs except those of his own body; and hence, failing his lawful issue, the king succeeds to him as last heir. In Scotland bastards may be legitimized in two ways; either by the subsequent intermarriage of the mother of the child with the father, as already mentioned, or by letters of legitimization from the sovereign. With respect to the last, however, it is to be observed, that letters of legitimization, be their clauses ever so strong, cannot enable the bastard to succeed to his natural father; for the king cannot, by any prerogative, cut off the private right of third parties. But, by a special clause in the letters of legitimation, he may renounce his right to the bastard's succession, failing descendants, in favour of him who would have been the bastard's heir had he been born in lawful wedlock, such renunciation encroaching upon no right competent to any third party. Formerly bastards in Scotland without issue of their own could not make a will, but this disability was removed by 6 Will. IV. c. 22. If bastards or other persons without kindred die intestate without wife or child, their effects go to the king as *ultimus hæres*, but a grant is usually made of them by letters patent, and the grantee becomes entitled to the administration.

The conflict of laws on the subject of legitimization by subsequent marriage yields some curious results. Thus, in the case of *Burtwhistle* v. *Vardill*, it was decided that a child born in Scotland of parents domiciled there, not married till after his birth, is legitimate by the law of Scotland, but cannot take real estate in England as heir. Again, a domiciled Scotchman had a son born in Scotland and then married the mother in Scotland. The son died seised of land in England, and it was held that the father could not inherit from the son. A domiciled Englishman, putative father of a child born in France of a French woman, having afterwards acquired a French domicile, married the mother and acknowledged the child as legitimate in the mode prescribed by the law of France It was held that he could not legitimize the child so as to enable it to share in a bequest to his children by a person in England. The law of England, while admitting the general maxim that the *status* of legitimacy must be tried by the law of the country where it originates, holds that the succession to real property must be determined by the *lex loci rei sitæ;* so that, for example, a legitimized Scotchman would be recognized as legitimate in England, but not legitimate so far as to take lands as heir.

The statistics of illegitimacy present some striking differences and uniformities, but it is only in the case of Scotland that we can be reasonably certain of the accuracy of the figures. The status of the child is not recorded in the English system of registration, but is a matter of inference from the facts stated by the parents. In 1873 illegitimacy varied in Scotland as follows. The proportion of illegitimate births was—

In the Insular rural districts	5·4	per cent.
,, Mainland rural districts	10·8	,,
,, Small towns	8·2	,,
,, Large towns	7·0	,,
,, Principal towns	9·1	,,

In the counties the percentage varied from 4 in Shetland, Ross, and Cromarty, 5 in Nairn, and 6·5 in Sutherland, to 11·1 in Forfar, 11·4 in Roxburgh, 13·7 in Kincardine, 14 in Aberdeen, 15·8 in Banff, 15·8 in Elgin and Dumfries, and 18·4 in Wigtown. Similar variations are shown by English statistics for 1859. Compare the highest (Cumberland, 11·4; Norfolk, 10·7; Westmoreland, 9·7) with the lowest (Monmouth and Middlesex, 4·7; and Surrey, 5). The metropolis stands at 4·2 With these local variations may be contrasted the steadiness with which the general average of illegitimacy is maintained. In England, for example, during nineteen years (1841-1859) the percentage fluctuated between 6 37 and 7, and during the last thirteen years of the period between 6·4 and 6·8. The returns of the Registrar-General show rather more fluctuation in Scotland during the period for which we have statistics (1855–1873), the figures being 7·8 in 1855, 8·5 in 1856, steadily rising to 10 in 1863, and 10·2 in 1866, and then steadily falling to 9·1 in 1872, and 9 in 1873. The statistics of different countries, so far as any proper comparison can be made between them, show differences equally remarkable. The order in which they stand would be something like the following:—Sardinia (illegitimates), 2·091 per cent.; Holland, 3·96; Spain, 5·6; Switzerland, 5·9; Tuscany, 6; England, 6·5; Finland, Belgium, Sicily, France, 7·8; Prussia, 7 to 8; Austria, Norway, Scotland, 9; Denmark, Sweden, Hanover, Iceland, Saxony, 15; Würtemberg, Bavaria, 20 (from Mr Lumley's paper in the *Journal of the Statistical Society* for June 1862). It will be seen that these differences cannot be explained on any consideration of religious belief or education. An inquiry made in Prussia in 1849 yielded the following results. The proportion of illegitimate to legitimate births was—

Among Protestants	1 to 10·78
,, Catholics	1 to 16·35
,, Mennonites	1 to 57·88
,, Jews	1 to 40

English and Scotch returns show that the proportion of illegitimacy is smaller in the town than in the country districts, but the same feature is not observed in Continental towns, as appears from the following returns, which, however, can in most cases be regarded as approximations only:—

In London the proportion is	4·2	per cent.
Birmingham, 1845 ,,	4·5	,,
Liverpool, ,, ,,	4	,,
Manchester, ,, ,,	6·7	,,
Leeds, ,,	6·4	,,

In Glasgow, 1861	the proportion is	8·6	per cent.
1873	,,	9·4	
Edinburgh, 1856	,,	7·6	,,
1873	,,	8·3	
Paris, 1851	,,	26·75	,,
1858	,,	26·35	
St Petersburg, 1828–29	,,	18·80	,,
Stockholm, 1831–35	,,	40·7	,,
Vienna, 1851	,,	51·7	,,
Milan, ,,	,,	34·0	,,
Prague, ,,	,,	46 7	.

(E R.)

BASTÍ, a district of British India, in the Benares division, under the jurisdiction of the Lieutenant-Governor of the N.W. Provinces, situated between 26° 23′ and 27° 30′ N. lat., and 82° 17′ and 83° 19′ 30″ E long. It is bounded on the N. by the independent state of Nepál, on the E. by the district of Gorakhpur, on the S. by the Ghagrá River, and on the W. by the district of Gondá in Oudh. The district stretches out in one vast marshy plain, draining towards the south-east, and traversed by the Raptí, Kuná, Bangangá, Masdih, Jamwár, Amí, and Katnehiá rivers. The tract lying between these streams consists of a rich alluvial deposit, more or less subject to inundations, but producing good crops of wheat and barley. Area of the district, 2787 square miles, population in 1872, 1,472,994 souls, residing in 6911 villages or townships, and 248,268 houses. The Hindus numbered 1,247,201, the Mahometans, 225,784; Christians, &c, 9 only. The Hindus, principally Rájput, belong to various clans. No manufacturing communities exist in the district, the entire population being cultivators. Rice and millet are the chief agricultural products. In 1870–71 the total revenue of the district amounted to £141,630, of which £132,274, or 93 per cent., was from land; the total expenditure amounting to £9518, 12s. The chief towns are—Mihdáwal, population 8124; Bastí, population 5087 The cost of the regular police force (exclusive of the village watch) was £15,896. In 1872–73 Bastí contained 185 schools, attended by 6810 pupils. The land revenue settlement was made for thirty years in 1864, with that of the district of Gorakhpur, of which Bastí formed a part till 1865, when it was erected into a separate district.

BASTIA, a fortified town and seaport on the eastern coast of the island of Corsica, and the capital of an arrondissement. Lat. 42° 41′ 36″ N, long. 9° 27′ 22″ E. It occupies a very picturesque situation, rising from the sea in the form of an amphitheatre, but the town itself is ill-built, and the streets are narrow and crooked. The harbour, which is defended by a citadel, has a narrow and difficult entrance. Bastia is the seat of a royal court for the island, and of tribunals of commerce and primary jurisdiction, and has a theatre, a military and a civil hospital, a communal college, a model school, a museum, and a library of 30,000 volumes. Its principal manufactures are soap, leather, liqueurs, and wax, and it exports oil, wine, coral, and various other products, being the principal seat of the import and export trade of the island. Bastia dates from the building of the Genoese Castle by Lionello Lomellino in 1383, and derives its name from the Bastion of St Charles. Under the Genoese it was long the principal stronghold in the north of the island, and the residence of the governor; and, in 1553, it was the first town attacked by the French. On the division of the island in 1797 into the two departments of Golo and Liamone, Bastia remained the capital of the former, but when the two were again united Ajaccio obtained the superiority. The city was taken by the English in 1745, and again in 1794. Population, 21,535. (See view in Lear's *Jour. in Corsica*, 1870.)

BASTIAT, FREDERIC, the son of a merchant of Bayonne, was born in that town on the 19th of June 1801. After being educated at the Colleges of Saint-Sever and of Sorèze, he entered in 1818 the counting-house of his uncle at Bayonne. Here his intensely active mind soon began to interest itself in the study of the principles of commerce, but he felt no enjoyment in the practical routine of mercantile life, and in 1825 retired to a property at Mugron, of which he became possessor on the death of his grandfather. Thus withdrawn from society, he devoted himself with eagerness to meditation and study, mastering the English and Italian languages and literatures, speculating on the problems of philosophy and religion, digesting the doctrines of Adam Smith and Say, of Charles Comte and Dunoyer, cultivating music, experimenting in farming, and talking over all that he read, thought, and desired, with his able, dearly loved, and life-long friend, M. Felix Coudroy. He welcomed with enthusiasm the Revolution of 1830. In 1831 he became a justice of peace of Mugron, and in 1832, a member of the Council-General of the Landes. In 1834 he published his first pamphlet. In 1840 he visited Spain and Portugal, and spent a few weeks in London. Between 1841–44 three pamphlets appeared from his pen, all, like his first brochure, on questions of taxation affecting local interests. During this period an accidental circumstance led him to become a subscriber to an English newspaper, the *Globe and Traveller*, through which he was made acquainted with the nature and progress of the crusade so vigorously and skilfully carried on by the Anti-Corn-Law League against Protectionist doctrines and practices. After closely studying the movement for two years he resolved to make his countrymen aware of its history and significance, and to inaugurate, if possible, a similar movement in France. To prepare the way he contributed in 1844 to the *Journal des Économistes* an article "Sur l'influence des tarifs Anglais et Français," which attracted great attention, and which he followed up by others, including the first series of his brilliant *Sophismes Économiques*.

In 1845 he came to Paris in order to superintend the publication of his *Cobden et la Ligue, ou l'agitation Anglaise pour la liberté des échanges*, and was very cordially received by the economists of the capital; from Paris he went to London and Manchester, and made the personal acquaintance of Cobden, Bright, and other leaders of the league. When he returned to France he found that his writings had been exerting a powerful influence; and in 1846 he assisted in organizing at Bordeaux the first French Free Trade Association. The rapid spread of the movement soon required him to abandon the sweet and fruitful leisure of his beloved Mugron for the feverish and consuming activity of Paris. During the eighteen months which followed this change his labours were prodigious. He acted as secretary of the central committee of the association, organized and corresponded with branch societies, waited on ministers, procured subscriptions, edited a weekly paper, the *Libre Echange*, contributed to the *Journal des Économistes*, and to three other periodicals, addressed meetings in Paris and the provinces, and delivered a course of lectures on the principles of political economy to students of the schools of law and of medicine. The cause to which he thus devoted himself, with a zeal and a self-denial most admirable in themselves, but fatal to his own health and life, appeared for a time as if it would be as successful in France as in England; but the forces in its favour were much weaker and those opposed to it were much stronger in the former country than in the latter, and this became always the more apparent as the struggle proceeded, until it was brought to an abrupt end by the Revolution of February 1848. This event allowed the socialism and communism which had been gathering and spreading in secret during the previous thirty years to

show themselves openly and boldly in singularly favourable circumstances. Louis Blanc, Victor Considérant, Pierre Leroux, J. P. Proudhon, and other representatives of these theories laboured zealously and effectively to gain to them the needy and uneducated masses of their countrymen, and to discredit as utterly evil the existing order of society In this grave crisis Bastiat nobly performed his duty. Although exhausted by the far too heavy labours in which he had been engaged, although robbed of his voice by the malady which was preying upon him, so that he could do but little to defend the truth from the tribune of the Constituent Assembly, he could still suggest wise counsels in the Committee of Finance of which he was vice-president, and he could still use his pen with a vigour and dexterity which made him capable of combating single-handed many opponents.

He wrote in rapid succession a series of brilliant and effective pamphlets and essays, showing how socialism was connected with protection, and exposing the delusions on which it rested. Thus within the space of two years there appeared *Propriéte et Loi*, *Justice et Fraternité*, *Propriété et Spoliation*, *L'État*, *Baccalauriet et Socialisme*, *Protectionisme et Communisme*, *Capital et Rente*, *Maudit Argent*, *Spoliation et Loi*, *Gratuité du Credit*, and *Ce qu'on voit et ce qu'on ne voit pas*. While thus occupied he was meditating the composition of a great constructive work, meant to renovate economical science by basing it on the principle that "interests, left to themselves, tend to harmonious combinations, and to the progressive preponderance of the general good." The first volume of this work *Les Harmonies Économiques* was published in the beginning of 1850. In the autumn of that year, when working on the second volume, the increase of his malady compelled him to repair to Italy. After lingering at Pisa and Florence he reached Rome, but only to die there on the 24th of December 1850, in the fiftieth year of his age. An affecting account of the last days of this illustrious martyr to the cause of economical science and political justice was published by his friend, M. Paillottet.

The life-work of Bastiat, in order to be fairly appreciated, requires to be considered in three aspects. (1.) He was the advocate of free trade, the opponent of protection. The general theory of free trade had, of course, been clearly stated and solidly established before he was born, and his desire to see its principles acted on in France was quickened and confirmed by the agitation of the Anti-Corn-Law League for their realization in England, but as no one denies it to have been a great merit in Cobden to have seen so distinctly and comprehensively the bearing of economical truths which he did not discover, no one should deny it to have been also a great merit in Bastiat. He did far more than merely restate the already familiar truths of free trade. He showed as no one before him had done how they were applicable in the various spheres of French agriculture, trade, and commerce. Now, the abstract theory of free trade is of comparatively little value; its elaboration so as to cover details, its concrete application, and its varied illustration are equally essential. And in these respects it owes more, perhaps, to Bastiat than to any other economist. In the *Sophismes Économiques* we have the completest and most effective, the wisest and the wittiest exposure of protectionism in its principles, reasonings, and consequences which exist in any language. (2.) He was the opponent of socialism. In this respect also he had no equal among the economists of France. He alone fought socialism hand to hand, body to body, as it were, not caricaturing it, not denouncing it, not criticizing under its name some merely abstract theory, but taking it as actually presented by its most popular representatives, considering patiently their proposals and arguments, and proving conclusively that they proceeded on false principles, reasoned badly, and sought to realize generous aims by foolish and harmful means. Nowhere will reason find a richer armoury of weapons available against socialism than in the pamphlets published by Bastiat between 1848 and 1850. These pamphlets will live, it is to be hoped, at least as long as the errors which they expose. (3.) He attempted to expound in an original and independent manner political economy as a science In combating, first, the Protectionists, and, afterwards, the Socialists, there gradually rose on his mind a conception which seemed to him to shed a flood of light over the whole of economical doctrine, and, indeed, over the whole theory of society, viz., the harmony of the essential tendencies of human nature The radical error, he became always more convinced, both of protectionism and socialism, was the assumption that human interests, if left to themselves, would inevitably prove antagonistic and anti-social, capital robbing labour, manufactures ruining agriculture, the foreigner injuring the native, the consumer the producer, &c.; and the chief weakness of the various schools of political economy, he believed he had discovered in their imperfect apprehension of the truth that human interests, when left to themselves, when not arbitrarily and forcibly interfered with, tend to harmonious combination, to the general good. Such was the point of view from which Bastiat sought to expound the whole of economical science. The sphere of that science he limited to exchange, and he drew a sharp distinction between utility and value. Political economy he defined as the theory of value, and value as "the relation of two services exchanged." The latter definition he deemed of supreme importance. It appeared to him to correct what was defective or erroneous in the conflicting definitions of value given by Adam Smith, Say, Ricardo, Senior, Storch, &c., to preserve and combine what was true in them, and to afford a basis for a more consistent and developed economical theory than had previously been presented. It has, however, found little acceptance, and Roscher, Cairnes, and others seem to have shown it to be ambiguous and misleading. A consequence of it on which he laid great stress was that the gratuitous gifts of nature, whatever be their utility, are incapable of acquiring value,—what is gratuitous for man in an isolated state remaining gratuitous for him in a social condition. Thus, land, according to Bastiat, is as gratuitous to men at the present day as to their first parents, the rent which is paid for it—its so-called value—being merely the return for the labour and capital which have been expended on its improvement. In the general opinion of economists he has failed to establish this doctrine, failed to show that the properties and forces of nature cannot be so appropriated as to acquire value. His theory of rent is nearly the same as Mr Carey's, *i.e.*, decidedly anti-Ricardian. His views on the growth of capital and interest, on landed property, competition, consumption, wages, and population, are independent, and, if not unqualifiedly true, at least richly suggestive. His *Œuvres Complètes* are in 7 vols. The first contains an interesting *Memoir* by M. Paillottet. The following articles on Bastiat may be specified,—Reybaud's in the *Revue des Deux Mondes*, Sept. 1, 1858; Macleod's in his *Dictionary of Political Economy;* and that of Cairnes in the *Fortnightly Review*, Oct. 1, 1870. There is a good statement of his distinctive views in Kautz, *Geschichte der National-Oekonomik*, ii. 578-584. His *Harmonies* have been well translated by Dr P. J. Stirling. (R. F.)

BASTILLE (from *bastir*, now *bâtir*, to build), in the earlier use of the word, was any fortified building forming part of a system of defence or attack; and the name was especially applied to several of the principal points in the ancient fortifications of Paris. In the reign of king John, or even earlier, the gate of Saint Antoine was flanked

by two towers; and in 1369 Hugues Aubriot, at the command of Charles V., changed it into a regular bastille or fort by the addition of six others of massive structure, the whole united by thick walls and surrounded by a ditch 25 feet wide. Various extensions and alterations were afterwards effected; but the building remained substantially what it was made by the vigorous provost, a strong and gloomy structure, with eight stern towers. As the ancient fortifications of the city were superseded, the use of the word bastille as a general designation gradually died out, and it became restricted to the castle of Saint Antoine, the political importance of which made it practically, long before it was actually, the only bastille of Paris. The building had originally a military purpose, and it appears as a fortress on several occasions in French history. When Charles VII. retook Paris from the English in 1436, all his opponents in the city took refuge in the Bastille, which they were prepared to defend with vigour, but the want of provisions obliged them to capitulate. In 1588 the duke of Guise took possession of the Bastille, gave the command of it to Bussy-Leclerc, and soon afterwards shut up the whole parliament within its walls, for having refused their adherence to the League. When Henri IV. became master of Paris he committed the command of the Bastille to Sully, and there he deposited his treasures, which at the time of his death amounted to the sum of 1,870,000 livres. On the 11th of January 1649, the Bastille was invested by the forces of the Fronde, and, after a short cannonade, capitulated on the 13th of that month. The garrison consisted of only twenty-two men. The Frondeurs concluded a peace with the court on the 11th of March; but it was stipulated by treaty that they should retain possession of the Bastille, which, in fact, was not restored to the king till the 21st of October 1651. In that year took place the famous fight of the Porte St Antoine between Condé and Turenne, on which occasion the forces oi Condé owed their safe retreat into Paris to the cannon of the Bastille.

At a very early period, however, the Bastille was employed for the custody of state prisoners, and it was ultimately much more of a prison than a fortress. According to the usual account, which one is tempted to ascribe to the popular love of poetical justice, the first who was incarcerated within its walls was the builder himself, Hugues Aubriot. Be this as it may, the duke of Nemours spent thirteen years there in one of those iron cages which Louis XI. called his *fillettes;* and Jacques d'Armagnac, Poyet, and Chabot were successively prisoners. It was not till the reign of Louis XIII. that it became recognized as a regular place of confinement; but from that time till its destruction it was frequently filled to embarrassment with men and women of every age and condition.

Of the treatment of prisoners in the Bastille very various accounts have been given even by those who speak from personal experience, for the simple reason that it varied greatly in different cases. The prisoners were divided into two main classes, those who were detained on grounds of precaution or by way of admonitory correction, and those who lay under presumption or proof of guilt. The former were subject to no investigation or judgment, and the length of their imprisonment depended on the will of the king; the latter were brought to trial in the ordinary courts or before special tribunals, such as that of the Arsénal,—though even in their case the interval between their arrest and their trial was determined solely by the royal decree, and it was quite possible for a man to grow old in the prison without having the opportunity of having his fate decided. Until guilt was established, the prisoner was registered in the king's name, and—except in the case of state prisoners of importance, who were kept with greater strictness and often in absolute isolation—he enjoyed a certain degree of comfort and freedom. Visitors were admitted under restrictions; games were allowed; and, for a long time, at least, exercise was permitted in open parts of the interior. Food was both abundant and good, at least for the better class of prisoners; and instances were not unknown of people living below their allowance and, by arrangement with the governor, saving the surplus. When the criminality of the prisoner was established, his name was transferred to the register of the "commission," and he became exposed to numerous hardships and even barbarities, which, however, belonged not so much to the special organization of the Bastille as to the general system of criminal justice then in force.

Among the more distinguished personages who were confined in this fortress during the reigns of Louis XIV., XV., and XVI., were the famous *Man of the Iron Mask*, Fouquet, the Marshal Richelieu, Le Maistre de Sacy, De Renneville, Voltaire, De Latude, Le Prévost de Beaumont, Labourdonnais, Lally, Cardinal Rohan, Linguet, and La Chalotais. While no detestation is too great for that system of "royal pantheism" which led to the unjust and often protracted imprisonment of even men of great ability and stainless character, it is unnecessary to give implicit credence to all the tales of horror which found currency during the excitement of the Revolution, and which historical evidence, as well as *a priori* considerations, tends to strip of their more dreadful features, and even in many cases to refute altogether. Within the last twenty or thirty years much light of an unexpected kind has been shed on the history of the Bastille from the pages of its own records. These documents had been flung out into the courts of the building by the Revolutionary captors, and after suffering grievous diminution and damage were finally stored up and forgotten in the vaults of the library of the (so-called) Arsénal. Here they were discovered in 1840 by François Ravaisson, who has since devoted himself, with rare patience, learning, and ability, to their arrangement, elucidation, and publication. Of the extent and value of his investigations some idea may be formed from the fact that the six volumes published cover only the interesting period from 1659 to 1681.

At the breaking out of the Revolution the Bastille was attacked by the Parisians; and, after a vigorous resistance, it was taken and razed to the ground on the 14th July 1789. At the time of its capture only seven prisoners were found in it. A very striking account of the siege will be found in Carlyle's *French Revolution*, vol. i. The site of the building is now marked by a lofty column of bronze, dedicated to the memory of the patriots of July 1789 and 1830. It is crowned by a gilded figure of Mercury spreading his pinions in the act of flight.

See the *Histories* of the Bastille by Renneville (7 tom. 12mo, 1713–24), Fougeret (8vo, 1833), Dufey de l'Yonne (8vo, 1834), and Arnould (7 tom. 8vo, 1843–44); and the *Memoirs* of Linguet (12mo, 1821, new ed.), Carra (3 tom. 8vo, 1787), Charpentier (3 tom. 8vo, 1789), and Latude (edited by Thierry, 3 tom. 18mo, 1791–92); also François Ravaisson, *Les Archives de la Bastille*, (6 vols. 8vo, 1866–73); and Charles Louandre, in *Revue des Deux Mondes*, 1874.

BASTWICK, DR JOHN, born at Writtle, in Essex, in 1593, was a physician at Colchester, whose celebrity rests on his strong opposition to the Roman Catholic ceremonial. About 1633 he printed in Holland a Latin treatise, entitled *Elenchus Religionis Papisticæ*, with *Flagellum Pontificis et Episcoporum Latialium;* and as the English prelates thought themselves aimed at, he was fined £1000 in the High Commission Court, excommunicated, and prohibited from practising physic, while his books were ordered to be burnt, and the author himself consigned to prison. Instead of

recanting, however, he wrote *Apologeticus ad Præsules Anglicanos*, and another book called *The Litany*, in which he exclaimed vehemently against the proceedings of that arbitrary court, and charged the bishops with an inclination to popery. Prynne and Burton coming under the lash of the Star-chamber court at the same time, they were all censured as turbulent and seditious persons, and condemned to pay a fine of £5000 each, to be set in the pillory, to lose their ears, and to undergo imprisonment for life in remote parts of the kingdom. The parliament in 1640 reversed these proceedings, and ordered Bastwick a reparation of £5000 out of the estates of the commissioners and lords who had persecuted him. The civil commotions which ensued prevented his receiving this *solatium* for his sufferings; but, in 1644, his wife had an allowance ordered for her own and her husband's maintenance. The place and time of his death are unknown. He seems in his later years to have shown bitter opposition to the Independents.

BAT, the common name of a well-marked group of Mammals forming the order *Cheiroptera* (*i.e.*, wing-handed), distinguished from all other members of their class by the possession of true organs of flight. These consist of a delicate membrane stretching from limb to limb on both sides of the body, enclosing the greatly elongated digits of the hand, and in many cases extending beyond the posterior limbs so as to include the tail. Their whole structure bears evidence of special adaptation to the purpose of sustained flight, while their mode of progression on the ground is as awkward as their aerial movements are graceful. The eyes of the bat are usually small, but the organs of the other senses in most cases attain extraordinary development. The external ear is generally large, as in the Long-eared Bat of Britain (*Plecotus auritus*), in which it is equal to the entire length of the body. In the group to which the Horse-shoe Bats (*Rhinolophus ferrum equinum*) belong, the nose is surrounded with leaf-like appendages, the purpose of which is by no means well determined, but which, probably, are as useful to the organ of smelling as is the greatly elongated auricle to that of hearing. In all bats the wing-membrane affords a vast expansion of the sense of touch, which is of such exquisite delicacy that bats which have been deprived of their sight, and as far as possible of hearing and smelling, are yet able by it alone to fly about in perfect security, avoiding, with apparent ease, all the obstacles that may be placed in their way. By Pliny and other early naturalists the bat, although known to suckle its young, was placed among Birds, and was generally regarded as a creature of ill omen, a superstitious feeling by no means extinct at the present day. Virgil, in speaking of the Harpies, generally understood to have been bats, describes them as "diræ obscenæque volucres." Our English ancestors formed a more correct estimate of the zoological position of these creatures as indicated by the name "flitter-mouse," still given to the bat in many parts of Britain. Bats are nocturnal or crepuscular in their habits, remaining suspended by day in the darkest recesses of woods and caverns, or in the most inaccessible parts of unfrequented buildings, and coming forth at twilight in search of food. This in the species found in Europe and America consists mainly of insects; while one species at least, the Vampire of America, sucks the blood of other mammals, although its powers in this respect have probably been much exaggerated. The Fruit-eating Bats (*Pteropus*) are confined to the warmer regions of Asia and Africa, and among these are to be found the largest members of the order, thus the Kalong of Java (*Pteropus javanicus*) measures 5 feet between the tips of its wings. In countries where the winter cold is sufficiently severe to cut off their usual sources of food, bats hibernate. Collecting in enormous numbers in their usual retreats and suspending themselves by their hind limbs, they become torpid, and remain so till the return of spring, bringing with it a revival of insect life, restores them to their wonted activity. About 130 species of bats are known, and these are widely distributed over every quarter of the globe, extending as far northward as latitude 60°; all the larger forms, however, occur in the warmer regions of the earth. Bats are found in most of the islands of the Indian and Pacific Oceans, forming in many of them the only indigenous mammals, a fact readily explained when viewed in connection with their remarkable power of flight. Fossil remains of insectivorous Cheiroptera have been found in the Eocene and later Tertiary deposits. See MAMMALIA.

BATAVIA, a large city and seaport on the north coast of the island of Java, and the capital of all the Dutch settlements in the East. It is situated on both sides of the river Jacatra or Tjiliwong, in a swampy plain at the head of a capacious bay. The streets are for the most part straight and regular, and many of them have a breadth of from 100 to 200 feet. In several cases there is a canal in the centre lined with stone, and defended by low parapets or banks, while almost every street and square is fringed with trees. The old town has greatly changed from what it was in the 18th century. It was then surrounded by strong fortifications, and contained a number of important buildings, such as the town-house (built in 1652 and restored in 1706), the exchange, the infirmary and orphan asylum, and the European churches. But the ramparts were long ago demolished, and most of the public edifices have either fallen into decay or been converted into magazines and warehouses. The great church which was finished in 1760, at an expense of £80,000, had to be taken down in consequence of its foundation having given way. Canals have been filled up, streets have been altered, and the general character of the place considerably modified. All the European inhabitants, except those immediately connected with the shipping, have removed to the New Town, which has been gradually formed by the integration of Weltevreden (*Well-content*), Molenvliet (*Mill-stream*), Rijswijk (*Rice-town*), Noordwijk (*North-town*), Koningsplein (*King's square*), and other suburban villages or stations. The situation of this modern part is higher and healthier; and the grandeur and variety of its buildings far surpass anything to be found in the older section of the city. The misplaced imitation of Dutch arrangements has been happily avoided, and the natural advantages of the situation and climate have been turned to account. The houses are frequently separated from each other by rows of trees.

As the chief city of the Dutch colonies in the East, Batavia contains numerous buildings connected with the civil and military organization of the Government. The chambers of the Council of the East Indies occupy a spacious edifice in Rijswijk, and the governor-general's hotel, or town residence, is situated in the same quarter. In the district of Weltevreden are the new palace, the barracks, and the artillery school, as well as the military and civil hospital, which can accommodate 600 patients, and not far off is the Frederik-Hendrik citadel, which was built in 1837. Further inland, at Meester Cornelis (known for its lake), is a school for under officers. The Koningsplein is a large open square for military manœuvres, about 390 feet long and 250 feet broad, surrounded by mansions of the wealthier classes. Noordwijk is principally inhabited by lesser merchants and subordinate officials. There is an orphan-asylum in the district of Parapatta, and a poor-house (*Diaconie armenhaus*) in Molenvliet. Besides those already mentioned, Batavia has various educational and scientific institutions of note. In 1851 the Government founded a medical school for

Javanese, and in 1860 the "Gymnasium William III." in which a comprehensive education is bestowed. A society of arts and sciences was established in 1778, a royal physical society in 1850, and a society for the promotion of industry and agriculture in 1853. In addition to the *Transactions* of these societies—many of which contain valuable contributions to their respective departments in their relation to the East Indies—a considerable number of publications are issued in Batavia. Among miscellaneous buildings of importance may be mentioned the public-hall known as the *Harmonie*, the freemasons' lodge, the theatre, the club-house, and several fine hotels.

The population of Batavia is very varied,—the Dutch residents being a comparatively small class, and greatly intermixed with Portuguese and Malays. Here are found members of the different Indian nations, originally slaves; Moors and Arabs, who are principally engaged in navigation, but also inhabit the Rua Malacoa district, and trade in gold and precious stones; Javanese, who are cultivators; and Malays, chiefly boatmen and sailors, and adherents of Mahometanism. But, perhaps, the most important Asiatic element is the Chinese, who are both numerous and industrious. They were long greatly oppressed by the Dutch Government in various paltry ways, and in 1740 they were massacred to the number of 12,000. But in spite of all this they have maintained their position, and now enjoy a happier lot. In 1832 the population was found to consist of 2800 Europeans, 80,000 natives, 25,000 Chinese, 1000 Arabs, and 9500 slaves, a total of 118,300 persons. The number of inhabitants is at present much less.

Batavia is still a great commercial depôt, though it has had to contend against the rivalry of Singapore. The bay is rendered secure by a number of islands at its mouth, and is capacious enough for a much larger traffic than it has ever seen; but it unfortunately grows very shallow towards the shore. Ships of 300 or 400 tons anchor about a mile and a half out; the river is navigable a couple of miles inland for vessels of 30 or 40 tons, but the entrance is narrow, and requires continual attention to keep it open.

The exports from Batavia to the other islands of the archipelago, and to the ports in the Malayan peninsula, are rice, sago, coffee, sugar, salt, oil, tobacco, teak timber and planks, Java cloths, brass wares, &c., and European, Indian, and Chinese goods. The produce of the Eastern Islands is also collected at its ports for re-exportation to India, China, and Europe,—namely, gold-dust, diamonds, camphor, benzoin, and other drugs; edible bird-nests, trepang, rattans, bees' wax, tortoise-shell, and dyeing woods from Borneo and Sumatra; tin from Banca; spices from the Moluccas; fine cloths from Celebes and Bali; and pepper from Sumatra. From Bengal are imported opium, drugs, and cloths; from China, teas, raw silk, silk piece-goods, varnished umbrellas, coarse China wares, nankeen, paper, and innumerable smaller articles for the Chinese settlers. British manufactures also are largely introduced. The number of British ships that entered in 1870 was 103, with a tonnage of nearly 31,000 tons, the total number of vessels of all nationalities being 783, with a tonnage of nearly 194,000.

Almost the only manufactures of any importance are the distillation of arrack, which is principally carried on by Chinese, the burning of lime and bricks, and the baking of pottery; and even the brick-making is in a decaying condition. The principal establishment for monetary transactions is the Java Bank, established in 1828 with a capital of £500,000; but there are also agencies belonging to the Bank of Rotterdam, and the Chartered Bank of India, Australia, and China, as well as a public savings bank.

The Government has a naval establishment at the island of Onrust, about six miles from the city; and among its other accommodations is a large iron floating dock capable of holding vessels 400 feet long. Since 1869, however, entrance has been refused to merchant ships, which, consequently, feel the lack of proper docks in the harbour. Proposals to build these and to extend the harbour, though frequently under discussion, have had no result. Tramways were introduced into the city in 1867, and are greatly patronized by the native population. A railway to Buitenzorg, where the Government botanical gardens are situated, was opened in 1871, the distance being about 40 miles inland.

Batavia owes its origin to the Dutch general John Petersen Coen, who, in 1619, took the town of Jacatra (which had been built on the ruins of the old Javanese town of Sunda Calappa), destroyed it, and founded in its stead the present city, which soon acquired a flourishing trade and increased in importance. The ruins of Jacatra are to be found between Batavia and Anjol. In 1699 Batavia was visited by a terrible earthquake, and the streams were choked by the mud from the volcano of Gunong Salak (7244 feet high), by which the climate was so affected that the city became notorious for its unhealthiness, and was in great danger of being altogether abandoned. In the twenty-two years from 1730 to 1752, 1,100,000 deaths are said to have been recorded. General Daendals, who was governor from 1808 to 1811, caused the ramparts of the town to be demolished, and began to form the nucleus of a new city at Weltevreden. By 1816 nearly all the Europeans had left the old town. In 1811 a British armament was sent against the Dutch settlements in Java, which had been incorporated by France, and to this force Batavia surrendered on the 8th of August. It was restored, however, to the Dutch by the treaty of 1814.

BATES, William, D.D., an eminent Nonconformist divine, born in November 1625. He was admitted to Emmanuel College, Cambridge, and removed thence to King's College in 1644. He was one of the commissioners at the conference in the Savoy, for reviewing the public liturgy, and was concerned in drawing up the exceptions to the Book of Common Prayer. Notwithstanding this he was appointed chaplain to Charles II. soon after the Restoration, and became minister of St Dunstan's in the West; but he was afterwards deprived of his benefice for nonconformity. Bates was of an amiable character, and enjoyed the friendship of the Lord-Keeper Bridgeman, the Lord-Chancellor Finch, the earl of Nottingham, and Archbishop Tillotson. He published *Select Lives of Illustrious and Pious Persons*, in Latin; and after his death all his works, except his *Select Lives*, were printed in one vol. fol.; again in 1723; and in 4 vols. 8vo, in 1815. He died in July 1699, in the 74th year of his age.

BATH, the chief town of Somersetshire, and, from the elegance of its buildings and the beauty of its situation, one of the finest cities in England, is situated mainly on the right bank of the river Avon, though a considerable extension has also taken place on the left. Communication between the two portions is afforded by several bridges, of which the most important are the Pulteney, the North Parade, the Cleveland, and the Grosvenor Suspension. The heights and slopes of the great western oolitic range, that rise like an amphitheatre from the river valley, are covered with the terraces and crescents of the city; it contains many fine public walks, and the vicinity presents a great variety of beautiful landscape. Its sheltered position renders the climate mild and agreeable. The houses are

mostly built of white freestone. Jointly with Wells, Bath is the head of a diocese, which is co-extensive with the county of Somerset. The Abbey Church is a handsome

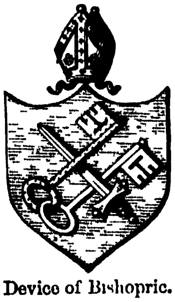
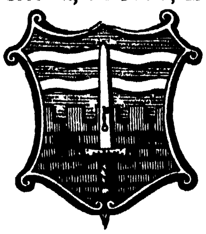
cruciform edifice, dating from 1499, with a quadrangular tower 162 feet high rising from the point of intersection. It is 210 feet in length from E. to W., and 126 in breadth from N. to S. The west front contains a curious representation of the founder's dream of the angels ascending and descending on Jacob's ladder. In the interior are the tombs of Quin, Nash, Malthus, Broome, Melmoth, and numerous minor celebrities; while several of the monuments are from the chisels of Bacon, Chantrey, and Flaxman. The church has been recently restored under the direction of Sir Gilbert Scott, at a cost of £20,000. There are about thirty other parish churches or chapels in Bath, as well as numerous nonconformist places of worship. St Swithin's, Walcot, may be mentioned as containing the tombs of Christopher Anstey and Madame d'Arblay. Among the most important educational institutions are the Free Grammar School, founded by Edward VI.; the Somersetshire College, established in 1858; the Royal School, for the education of the daughters of military officers, founded in 1865; the Bath College in Sydney Place; the School of Art; the Roman Catholic College at Prior Park, which was formerly the mansion of Ralph Allen, the friend and patron of Fielding; and the Wesleyan College at Kingswood. There are several buildings of considerable pretension connected with the baths from which the town derives its name. The springs supply six distinct establishments, namely, the King's, Queen's, Hot, Cross, Abbey, and Grand Pump Room Hotel baths. Of these the oldest is the King's,



Device of Bishopric.

which was enclosed in 1236. The pump-room is 85 feet in length by 56 in breadth and 34 in height; it contains a marble statue to Beau Nash. The Queen's was built in 1597; and the Cross Bath dates from 1790. The temperature varies in the different springs from 117° to 120° Fahr., and the specific gravity of the hot bath is 1·002. Dr. Daubeny in 1833 found that the daily evolution of nitrogen gas amounted to 250 cubic feet; and Professor Ramsay has calculated that if the mineral ingredients of the waters were solidified they would form in one year a column 9 feet in diameter and 140 feet in height. The principal substances in solution are sulphates of lime and soda and chlorides of sodium and magnesium. The waters are very beneficial in cases of palsy, rheumatism, gout, leprosy, neuralgia, sciatica, chorea, diseases of the liver, and cutaneous and scrofulous affections. The influx of visitors, varying from 10,000 to 14,000 during the season, has greatly stimulated the adornment of the town. The Assembly rooms, built by Wood the younger, at a cost of £20,000, were opened in October 1771, and for elegance, comfort, and convenience, are not surpassed by any similar rooms in the kingdom. The theatre, which is one of the best out of London, was opened in 1863, the former building having been burnt in 1862. The Literary and Scientific Institution, founded in 1826, is a handsome building of the Doric order, and contains a laboratory, a lecture-room, a museum (with numerous Roman antiquities and ornithological specimens), and an extensive library, in which is the Chapman collection illustrative of the history of Bath. The Rev Leonard Blomefield (late Jenyns) has presented his fine library of natural history and science (including his herbarium) to the institution. The Guild-hall, with an elegant Grecian front, was founded in 1766; and the market-halls were reconstructed about 1863. Among the charitable institutions are the Mineral Water Hospital, opened in 1742, and extended in 1861; the Royal United Hospital, opened in 1826; Bellot's Hospital, which dates from 1611, though the present building was erected in 1859; St Catherine's Hospital, founded by Edward VI.; St John's, founded by Bishop Fitz Joceline in 1174; and the Ear-and-Eye Infirmary, established in 1837. There are six banks, besides a savings-bank. The Sydney gardens have been open since 1795, and are frequently employed for public exhibitions and amusements; the Victoria Park, opened by the queen, when Princess Victoria, in 1830, is such as any city might be proud of. The corporation consists of a mayor, fourteen aldermen, and forty-two councillors, and the town returns two members to parliament. Several newspapers are published weekly. The Great Western Railway connects Bath with London, Bristol, Salisbury, Wells, Weymouth, &c., from the first of which it is 107 miles distant; the Midland line is connected with Bath by a junction at Mangotsfield; and ready access to the south has recently been obtained by the opening of the Somerset and Dorset line. The Kennet and Avon canal, which joins the Thames at Reading, affords water communication with the metropolis. The population of the municipal borough was 54,240 in 1851, 52,528 in 1861, and 52,557 in 1871, nearly 60 per cent. of the last number being females. In 1871 the parliamentary borough contained 53,704 persons.



City Arms.

According to the legend to which the inhabitants adhered till the middle of the 18th century, Bath was founded by the British king Bladud; but its origin cannot be historically traced to an earlier date than the 1st century, when the Romans established here the city of *Aquæ Solis*, numerous remains of which have at various times been

discovered. During the Saxon period the chief events in its annals are the foundation of an abbey by Offa in 775, and the coronation of Edgar in 973. In the reign of William Rufus the city was reduced to ashes, but it soon recovered its prosperity under its abbot John of Villula, and his successors. Richard Cœur de Lion granted its first charter as a free borough, and about the same time the foundations were laid of its wool manufactures. In 1297 the city was first represented in parliament; in 1447 it obtained a charter from Henry VI., and one from Queen Elizabeth in 1590. In the 18th century it became the most fashionable watering-place in England, and was greatly extended under the direction of the architects Wood.

See Warner's *History and Antiquities of Bath*, 1801; Mainwaring's *Collectanea*; C. P. Russell, *On the Growth of Bath*, read before the Arch. Inst., 1858; *Ancient Landmarks of Bath*, by C. E. Davis; Wright's *Hist. Guide to Bath*, 1864, Earle's *Guide to Bath*, 1864; Lyell's *Inaugural Address before Brit. Assoc.*, 1864; Sir G. Jackson's *Archives of Bath*, 2 vols., 1873; Peach, *Rambles about Bath*, 1875; Scarth, *Aquæ Solis, or Notices of Roman Bath*, 1864.

BATH, a city and port of the United States of North America, chief town of the county of Sagadahock in Maine. It is situated on the W. bank of the Kennebec, about twelve miles from the sea, and forms a station on the branch railway from Brunswick to Rockland. The prosperity of the town depends almost entirely on its shipping and fisheries; and its manufacturing industries are nearly all auxiliary to the one department of shipbuilding, in which it competes with the chief American centres of the trade. It has a fine custom-house built of granite. The city was settled in 1756, incorporated in 1780, and raised to the rank of a city in 1850. Population (1870), 7371

BATH, KNIGHTS OF THE. See HERALDRY and KNIGHTHOOD.

BATHGATE, a town of Scotland, in the county of Linlithgow, 19 miles from Edinburgh, and 26 from Glasgow, with both which it has direct communication by railway. The town is irregularly built, and has no buildings of importance except a well-endowed academy. The district is rich in limestone, coal, shale, and ironstone, which afford employment to a large part of the population. Paraffin and chemicals are extensively manufactured, and there are glass-works and flour-mills. Population (1871), 4491.

BATHS. In the ordinary acceptation of the word a bath is the immersion of the body in a medium different from the ordinary one of atmospheric air, which medium is usually common water in some form. In another sense it includes the nature of the different media that may be used, and of the various arrangements by which they are applied. Perhaps the simplest method of presenting a general view of the whole subject is first to give an outline of the history of baths in all ages, and next to give some account of the principles on which baths act on the human system.

Ancient Baths.—Bathing, as serving both for cleanliness and for pleasure, has been almost instinctively practised by nearly every people. The most ancient records mention bathing in the rivers Nile and Ganges. From an early period the Jews bathed in running water, used both hot and cold baths, and employed oils and ointments. So also did the Greeks; their earliest and commonest form of bathing was swimming in rivers, and bathing in them was practised by both sexes. Warm baths were, according to Homer, used after fatigue or exercise. The Athenians appear for a long time only to have had private baths, but afterwards they had public ones: the latter seem to have originated among the Lacedæmonians, who invented the hot-air bath, at least the form of it called after them, the *Laconicum*. Although the baths of the Greeks were not so luxurious as those of some other nations, yet effeminate people were accused among them of using warm baths in excess; and the bath servants appear to have been rogues and thieves, as in later and larger establishments. The Persians must have had handsomely equipped baths, for Alexander the Great admired the luxury of the baths of Darius.

But the baths of the Greeks, and probably of all Eastern nations, were on a small scale as compared with those which eventually sprung up among the Romans. In early times the Romans used after exercise to throw themselves into the Tiber. Next, when ample supplies of water were brought into the city, large *piscinæ*, or cold swimming baths, were constructed, the earliest of which appear to have been the *piscina publica* (312 B.C.), near the Circus Maximus, supplied by the Appian aqueduct, the *lavacrum* of Agrippina, and a bath at the end of the Clivus Capitolinus. Next, small public as well as private baths were built; and with the empire more luxurious forms of bathing were introduced, and warm became far more popular than cold baths.

Public baths or *balneæ* were first built in Rome after Clodius brought in the supply of water from Præneste. After that date baths began to be common both in Rome and in other Italian cities; and private baths, which gradually came into use, were attached to the villas of the wealthy citizens. Mæcenus was one of the first who built public baths at his own expense. After his time each emperor, as he wished to ingratiate himself with the people, lavished the revenues of the state in the construction of enormous buildings, which not only contained suites of bathing apartments, but included gymnasia, and sometimes even theatres and libraries. Such enormous establishments went by the name of *thermæ*. The principal thermæ were those of Agrippa 21 B.C., of Nero 65 A.D., of Titus 81, of Domitian 95, of Commodus 185, of Caracalla 217, and still later those of Diocletian 302, and of Constantine. The technical skill displayed by the Romans in rendering their walls and the sides of reservoirs impervious to moisture, in conveying and heating water, and in constructing flues for the conveyance of hot air through the walls, was of the highest order.

The Roman baths contained swimming baths, warm baths, baths of hot air, and vapour baths. The chief rooms (which in the largest baths appear to have been mostly distinct, whereas in smaller baths one chamber was made to do duty for more than a single purpose) were the following:—(1.) The *apodyterium* or *spoliatorium*, where the bathers undressed; (2.) the *alipterium* or *unctuarium*, where oils and ointments were kept (although the bathers often brought their own pomades), and where the *aliptæ* anointed the bathers; (3.) The *frigidarium*, or cool room, *cella frigida*, in which usually was the cold bath, the *piscina* or *baptisterium*; (4.) The *tepidarium*, a room moderately heated, in which the bathers rested for a time, but which was not meant for bathing; (5.) The *calidarium* or heating room, over the *hypocaustum* or furnace; this in its commonest arrangement had at one end a warm bath, the *alveus* or *calida lavatio*; at the other end in a sort of alcove was (6.) The *sudatorium* or *laconicum*, which usually had a *labrum* or large vessel containing water, with which bathers sprinkled themselves to help in rubbing off the perspiration. In the largest baths the laconicum was probably a separate chamber, a circular domical room with recesses in the sides, and a large opening in the top; but there is no well-preserved specimen, unless that at Pisa may be so regarded. In the drawing of baths from the thermæ of Titus (fig. 1), the laconicum is represented as a small cupola rising in a corner of the calidarium. It is known that the temperature of the laconicum was regulated by drawing up or down a metallic plate or *clypeus*. Some think that this clypeus was directly over the flames of the hypocaustum, and that when it was withdrawn, the flames must have sprung into the laconicum. Others, and apparently they have Vitruvius on their side, think that the clypeus was

drawn up or down only from the aperture in the roof, and that it regulated the temperature simply by giving more or less free exit to the hot air. The question must for the present remain unsettled; if the laconicum was only one end of the calidarium, it is difficult to see how that end of the room was kept so much hotter than the rest of it; on the other hand to have had flames actually issuing from the laconicum, must have caused smoke and soot, and have been very unpleasant. The most usual order in which the rooms were employed seems to have been the following, but there does not appear to have been any absolute uniformity of practice then, any more than in modern Egyptian and Turkish baths. Celsus recommends the bather first to sweat a little in the tepidarium with his clothes on, to be anointed there, and then to pass into the calidarium; after he has sweated freely there he is not to descend into the solium or cold bath, but to have plenty of water poured over him from his head,—first warm, then tepid, and then cold water,—the water being poured longer over his head than on the rest of the body; next to be scraped with the strigil, and lastly to be rubbed and anointed.

The warmest of the heated rooms, *i.e.*, the calidarium and laconicum, were heated directly from the hypocaustum, over which they were built or suspended (*suspensura*); while from the hypocaustum tubes of brass, or lead, or pottery carried the hot air or vapour to the walls of the other rooms. The walls were usually hollow, so that the hot air could readily circulate.

The water was heated ingeniously. Close to the furnace, about 4 inches off, was placed the *calidarium*, the copper (*ahenum*) for boiling water, near which, with the same interval between them, was the copper for warm water, the *tepidarium*, and at the distance of 2 feet from this was the receptacle for cold water, or the *frigidarium*, often a plastered reservoir. A constant communication was kept up between these vessels, so that as fast as hot water was drawn off from the calidarium a supply was obtained from the tepidarium, which, being already heated, but slightly reduced the temperature of the hotter boiler. The tepidarium, again, was supplied from the frigidarium, and that from an aqueduct. In this way the heat which was not taken up by the first boiler passed on to the second, and instead of being wasted, helped to heat the second—a principle which has only lately been introduced into modern furnaces. In the case of the large thermæ the water of an aqueduct was brought to the *castellum*, or top of the building, and was allowed to descend into chambers over the hypocaustum, where it was heated and transmitted in pipes to the central buildings. Remains of this arrangement are to be seen in the baths of Caracalla. The general plan of such buildings will be more clearly understood after an examination of the accompanying illustrations. In the

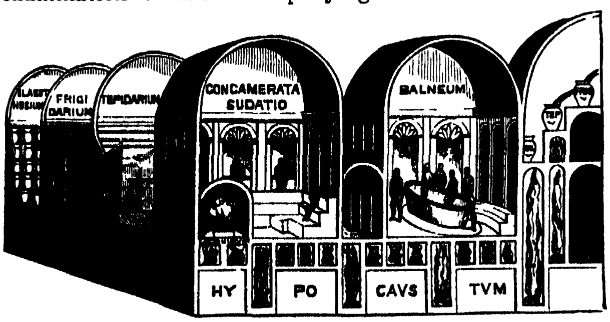


FIG. 1.—Roman Baths.

well-known drawing (fig. 1) found in the baths of Titus, the name of each part of the building is inscribed on it. The small dome inscribed laconicum directly over the furnace, and having the clypeus over it, will be observed in the corner of the chamber named concamerata sudatio. The vessels for water are inscribed, according to their temperature, with the same names as some of the chambers, frigidarium, tepidarium, and calidarium.

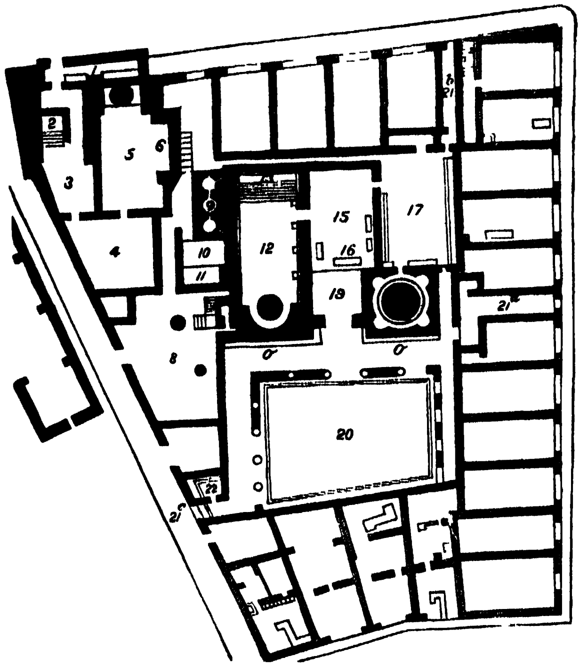

FIG. 2.—Ground-Plan of the Baths of Pompeii.

The baths of Pompeii (as shown in fig. 2) were a double set, and were surrounded with tabernæ or shops, which are marked by a lighter shade. There were streets on four sides; and the reservoir supplying water was across the street in the building on the left hand of the cut. There were three public entrances—21*a*, 21*b*, 21*c*—to the men's baths and one to the women's. The furnaces (9) heated water, which was conveyed on one side to the larger baths of the men, on the other to the women's. Entering from the street at 21*c* there was a latrina on the left hand (22). From this it was usual to proceed to a court (20) surrounded by pillars, where servants were in attendance. There is some doubt as to the purpose to which the room (19) was devoted. Leaving the hall a passage conducted to the apodyterium or dressing-room (17), at one end of it is the frigidarium, baptisterium, or cold plunge bath (18). Entering out of the apodyterium is the tepidarium, or warming-room (15), which most probably was also used as the alipterium or anointing-room. From it bathers passed into the hot room or calidarium (12), which had at one end the alveus or calida lavatio (13), at the other end the labrum (14). This end of the calidarium served as the laconicum. The arrangements of the women's baths were similar, but on a smaller scale. The calidarium (5) had the labrum (7) at one end, and the alveus (6) was in one side of the room. The general arrangements of a calidarium are well illustrated by the accompanying section (fig. 3) of a bath discovered at Tusculum. The disposition of the parts is the same as at Pompeii. We here have the calidarium supported on the pillars of the fornax, the suspensura. The alveus (3) is

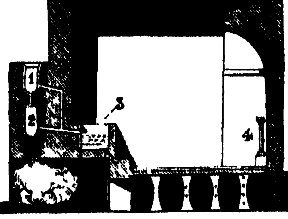

FIG. 3.—Section of Bath discovered at Tusculum, showing the calidarium (hot room).

at one end, and the labrum (4) at the other. (1) and (2) are the vessels for water over the fornax; and the passages in the roof and walls for the escape of heated air will be observed.

A clear idea of the relative position of the different rooms, and some slight indication of their ornamentation, will be obtained from the accompanying woodcut (fig. 4). The flues

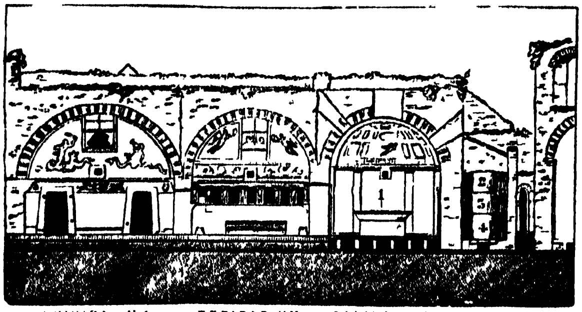

FIG. 4.—Section of Baths of Pompeii.

under the calidarium and the labrum (1) may be observed, as also the opening in the roof above. (2), (3), and (4) mark the vessels for water which are placed between the men's baths on the left and the women's on the right.

The arrangements of the *thermæ* were mainly those of the balneæ on a larger scale. Some idea of their size may be gathered from such facts as these, that in the baths of Diocletian one room has been transmuted into a church of most imposing proportions, and that the outside walls of the baths of Caracalla extend about a quarter of a mile on each of the four sides. A visit to the remains of the baths of Titus, of Diocletian, or of Caracalla impresses the mind strongly with a sense of the vast scale on which they were erected, and Ammianus's designation of them as provinces appears scarcely exaggerated. It is said that the baths of Caracalla contained 1600, and those of Diocletian

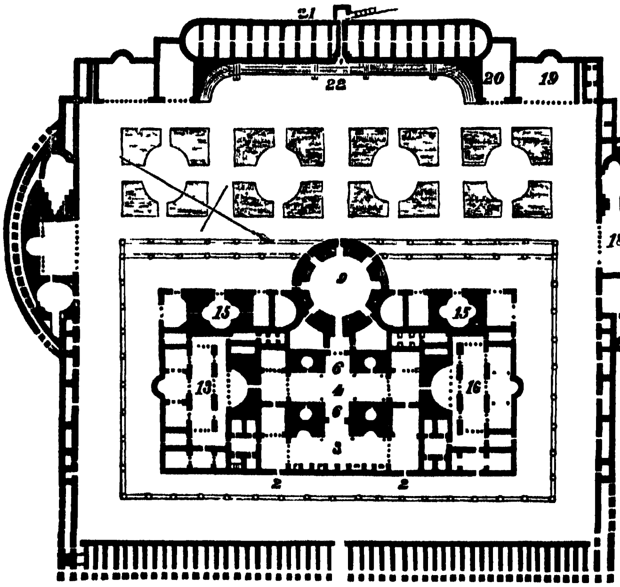

FIG. 5.—Ground Plan of the Baths of Caracalla.

3200 marble seats for the use of the bathers. In the largest of the thermæ there was a stadium for the games of the young men, with raised seats for the spectators. There were open colonnades and seats for philosophers and literary men to sit and discourse or read their productions aloud, or for others to discuss the latest news. Near the porticoes, in the interior open space, rows of trees were planted. There was a *sphæristerium*, or place for playing ball, which was often over the apodyterium; but it must be confessed that the purposes of many portions of these large edifices have not been made out in as satisfactory a way as those of smaller baths. A more definite idea of the thermæ can be best got by an examination of the accompanying plan of the baths of Caracalla (fig. 5). A good deal of the plan is conjectural,—the restorations being marked by lighter shading.

At the bottom of the plan is shown a long colonnade, which faces the street, behind which was a series of chambers, supposed to have been separate bathing-rooms. Entering by the opening in its centre, the visitor passes what was probably an inner colonnade round the main building. Passing in by either of the gates (2, 2), he reaches the large chamber (3), which has been variously called the natatio or large swimming bath, or the tepidarium. The great central room (4) in all probability was the calidarium, with two labra (6, 6) on opposite sides, and with four alvei, one in each corner, represented by small circular dots. (9) has been regarded by some as the laconicum, although it appears very large for that purpose. The rooms (15, 15) have been variously described as baptisteria and as laconica. Most authors are agreed in thinking that the large rooms (13) and (16) were the sphæristeria, or places for playing ball.

Returning to the outside, (1) and (18) and the corresponding places on the other side, are supposed to have been the exedræ for philosophers, and places corresponding to the Greek xysti. (20) and (19) have been considered to be servants' rooms. (22) was the stadium, with raised seats for the spectators. The space between this and the large central hall (9) was planted with trees, and at (21) the aqueduct brought water into the castellum or reservoir, which was on an upper story. There were upper stories in most portions of the building, and in these probably were the libraries and small theatres

The magnificence of many of the thermæ and their luxurious arrangements were such that some writers, as Seneca, are quite lost in their descriptions of them. The piscinæ were often of immense size,—that of Diocletian being 200 feet long,—and were adorned with beautiful marbles. The halls were crowded with magnificent columns, and were ornamented with the finest pieces of statuary. The walls, it has been said, were covered with exquisite mosaics that imitated the art of the painter in their elegance of design and variety of colour. The Egyptian syenite was encrusted with the precious green marbles of Numidia. The rooms contained the works of Phidias and Praxiteles. A perpetual stream of water was poured into capacious basins through the wide mouths of lions of bright and polished silver; water issued from silver, and was received on silver. "To such a pitch of luxury have we reached," says Seneca, "that we are dissatisfied if we do not tread on gems in our baths."

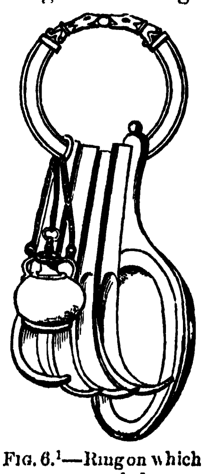

FIG. 6.[1]—Ring on which are suspended some of the articles in use in the Alipterium.

The richer Romans used every variety of oils and pomades (*smegmata*); they scarcely had true soaps. The poorer class had to be content with the flour of lentils, an article used at this day for the same purpose by Orientals. The most important bath utensil was the strigillus, a curved instrument made of metal, with which the skin was scraped and all sordes removed.

The bath servants assisted in anointing, in using the strigillus, and in various other menial offices. The poorer classes had to use their strigils themselves. The

[1] The figure represents four strigils, in which the hollow for collecting the oil or perspiration from the body may be observed. There is also a small ampulla or vessel containing oil, meant to keep the strigils smooth, and a small flat patera or drinking vessel, out of which it was customary to drink after the bathing was finished.

various processes of the aliptæ seem to have been carried on very systematically.

The hot baths appear to have been open from 1 P.M. till dark. It was only one of the later emperors that had them lighted up at night. When the hot baths were ready (for, doubtless, the plunge baths were available at an earlier hour), a bell or *æs* was rung for the information of the people. Among the Greeks and Romans the eighth hour, or 1 o'clock, before their dinner, was the commonest hour for bathing. The bath was supposed to promote appetite, and some voluptuaries had one or more baths after dinner, to enable them to begin eating again; but such excesses, as Juvenal tells us, occasionally proved fatal. Some of the most effeminate of the emperors are said to have bathed seven or eight times in the course of the day. In early times there was delicacy of feeling about the sexes bathing together—even a father could not bathe with his sons; but latterly, under most of the emperors, men and women often used the same baths. There frequently were separate baths for the women, as we see at Pompeii, or at Badenweiler; but although respectable matrons would not go to public baths, promiscuous bathing was common during the empire.

The public baths and thermæ were under the more immediate superintendence of the ædiles. The charge made at a public bath was only a quadrans or quarter of an as, about half a farthing. Yet cheap though this was, the emperors used to ingratiate themselves with the populace, by making the baths at times gratuitous.

Wherever the Romans settled, they built public baths; and wherever they found hot springs or natural stufæ, they made use of them, thus saving the expense of heating, as at the *myrteta* of Baiæ, or the *aquæ solis* of Bath. In the cities there appear to have been private baths for hire, as well as the public baths; and every rich citizen had a set of baths attached to his villa, the fullest account of which is given in the *Letters* of Pliny, or in Ausonius's *Account of a Villa on the Moselle*, or in Statius's *De Balneo Etrusco*. Although the Romans never wholly gave up cold bathing, and that practice was revived under Augustus by Antonius Musa, and again under Nero by Charmis (at which later time bathing in the open sea became common), yet they chiefly practised warm bathing (*calida lavatio*). This is the most luxurious kind of bathing, and when indulged to excess, is enervating. The women were particularly fond of these baths, and were accused, at all events in some provincial cities, of drunkenness in them.

The unbounded licence of the public baths, and their connection with modes of amusement that were condemned, led to their being to a considerable extent proscribed by the early Christians. The early fathers wrote that bathing might be practised for the sake of cleanliness or of health, but not of pleasure; and Gregory the Great saw no objection to baths being used on Sunday. About the 5th century many of the large thermæ in Rome fell into decay. The cutting off of the aqueducts by the Huns, and the gradual decrease of the population, contributed to this. Still it is doubtful whether bathing was ever disused to the extent that is usually represented. It was certainly kept up in the East in full vigour at Alexandria and at Brusa. Hot bathing, and especially hot air and vapour baths, were adopted by the Mahometans, and the Arabs brought them with them into Spain. The Turks, at a later time, carried them high up the Danube, and the Mahometans spread or, it may be more correct to say, revived their use in Persia and in Hindustan. The Crusaders also contributed to the spread of baths in Europe, and hot vapour baths were specially recommended for the leprosy so prevalent in those days. After the commencement of the 13th century there were few large cities in Europe without hot vapour baths. We have full accounts of their regulations,—how the Jews were only allowed to visit them once a week, and how there were separate baths for lepers. In England they were called hothouses. Erasmus, at the date of the Reformation, spoke of them as common in France, Germany, and Belgium; he gives a lively account of the mixture of all classes of people to be found in them, and would imply that they were a common adjunct to inns. They seem after a time to have become less common, though Montaigne mentions them as being still in Rome in his day. In England the next revival of baths was at the close of the 17th century, under the Eastern name of Hummuns, or the Italian name of Bagnios. As these, like more recent revivals of them, were avowedly on the principle of the Turkish baths, that species of bath must be briefly noticed. But before doing so, we must observe that there were several considerable epochs in the history of baths, one in the commencement of the 18th century, when Floyer and others recalled attention to cold bathing, of which the virtues had long been overlooked. In the middle of the century also, Russell and others revived sea-bathing in England, and were followed by others on the Continent, until the value of sea-bathing became fully appreciated. Later in the same century the experiments of Currie on the action of complete or of partial baths on the system in disease attracted attention; and though forgotten for a while, they have borne abundant fruit in more recent times

Modern Baths.—It is uncertain how far the Turkish and Egyptian and even the Russian baths are to be regarded merely as successors of the Roman baths, because the principle of vapour baths has been known to many nations in a very early period of civilization. Thus the Mexicans and Indians were found using small vapour baths. The ancient inhabitants of Ireland and of Scotland had some notion of their use, and the large vapour baths of Japan, now so extensively employed, are probably of independent origin. We extract at some length accounts of Turkish and of Russian baths, as they illustrate the practices of the ancient Roman and of modern Turkish baths. The first is taken from Lane's work *On the Modern Egyptians*:—"The building consists of several apartments, all of which are paved with marble, chiefly white. The inner apartments are covered with domes, which have a number of small glazed apertures for the admission of light. The bather, on entering, if he has a watch or purse, gives them in charge to the keeper of the bath. The servant of the bath takes off his shoes, and supplies him with a pair of wooden clogs. The first apartment has generally three or four *leewans* (raised parts of the floor used as couches) cased with marble, and a fountain of cold water, which rises from an octagonal basement in the centre. One of the leewans, which is meant for the higher classes, is furnished with cushions or mats.

"In warm weather bathers usually undress in this room; in winter they undress in an inner room, called the *beytowwal*, or first chamber, between which and the last apartment there is a passage often with two or three latrines off it. This is the first of the heated chambers. It generally has two raised seats. The bather receives a napkin in which to put his clothes, and another to put round his waist—this reaches to the knees; a third, if he requires it, is brought him to wind round his head, leaving the top of it bare; a fourth to put over his chest, and a fifth to cover his back. When the bather has undressed, the attendant opens to him the door of the inner and principal apartment. This in general has four leewans, which gives it the form of a cross, and in the centre a fountain of hot water rises from a small shallow basin. The centre room, with the adjoining ones, forms almost a square. The beytowwal

already mentioned is one of them. Two small chambers which adjoin each other, one containing a tank of hot water, the other containing a trough, over which are two taps one of hot and one of cold water, occupy the two other angles; while the fourth angle of the square is occupied by the chamber which contains the fire, over which is the boiler.

"The bather having entered this apartment soon perspires profusely from the humid heat which is produced by the hot water of tanks and fountains, and by the steam of the boiler. The bather sits on one of the marble seats, or lies on the leewan, or near one of the tanks, and the operator then commences his work. The operator first cracks aloud every joint in the body. He makes the vertebræ of the back and even of the neck crack. The limbs are twisted with apparent violence, but so skilfully, that no harm is ever done. The operator next kneads the patient's flesh. After this he rubs the soles of the feet with a kind of rasp of baked clay. There are two kinds of rasps, one porous and rough, one of fine smooth clay Those used by ladies are usually encased in thin embossed silver. The next operation is rubbing the bather's flesh with a small coarse woollen bag, after which the bather dips himself in one of the tanks He is next taken to one of the chambers in the corner, and the operator lathers the bather with fibres of the palm tree, soap and water. The soap is then washed off with water, when the bather having finished washing, and enveloped himself in dry towels, returns to the beytowwal and reclines. Here he generally remains an hour to an hour and a half, sipping coffee and smoking, while an attendant rubs the soles of the feet and kneads the body and limbs. The bather then dresses and goes out."

The following description of a Russian bath is from Kohl's *Russia*:—"The passage from the door is divided into two behind the check-taker's post, one for the male, one for the female guests. We first enter an open space, in which a set of men are sitting in a state of nudity on benches, those who have already bathed dressing, while those who are going to undergo the process take off their clothes. Round this space or apartment are the doors leading to the vapour-rooms. The bather is ushered into them, and finds himself in a room full of vapour, which is surrounded by a wooden platform rising in steps to near the roof of the room. The bather is made to lie down on one of the lower benches, and gradually to ascend to the higher and hotter ones. The first sensation on entering the room amounts almost to a feeling of suffocation After you have been subjected for some time to a temperature which may rise to 145°, the transpiration reaches its full activity, and the sensation is very pleasant The bath attendants come and flog you with birchen twigs, cover you with the lather of soap, afterwards rub it off, and then hold you over a jet of ice-cold water. The shock is great, but is followed by a pleasant feeling of great comfort and of alleviation of any rheumatic pains you may have had. In regular establishments you go after this and lie down on a bed for a time before issuing forth But the Russians often dress in the open air, and instead of using the jet of cold water, go and roll themselves at once in the snow."

Turkish baths have, with various modifications, become popular in Europe. The Russian baths were introduced into most German towns about half a century ago. They had a certain limited amount of popularity, but did not take firm root. Another class practically owes its origin to Dr Barter and Mr Urquhart It professed to be founded on the Turkish bath, but in reality it was much more of a hot air bath, *i e.*, more devoid of vapour than either Roman or Turkish baths ever were, for it is doubtful whether in any case the air of the laconicum was free from vapour. These baths, with their various modifications, have become extremely popular in Great Britain, in Germany, and in Northern Europe, but have, curiously enough, never been used extensively in France, notwithstanding the familiarity of the French with Turkish baths in Algiers.

In England hot air baths are now employed very extensively. They are often associated with Turkish and electric baths, and with the usual processes of hydropathic treatment.

Bathing among the ancients was practised in various forms It was sometimes a simple bath in cold or in tepid water; but at least, in the case of the higher orders, it usually included a hot air or vapour bath, and was followed by affusion of cold or warm water, and generally by a plunge into the piscina. In like manner the order varies in which the different processes are gone through in Turkish baths in modern Europe. Thus in the new baths in Vienna, the process begins by immersion in a large basin of warm water. Sudation is repeatedly interrupted by cold douches at the will of the bathers, and after the bath they are satisfied with a short stay in the cooling-room, where they have only a simple sheet rolled round them. In Copenhagen and in Stockholm the Oriental baths have been considerably modified by their association with hydropathic practices.

This leads us to notice the introduction of hydropathy. Although cold baths were in vogue for a time in Rome, warm baths were always more popular. Floyer, as we have seen, did something to revive their use in England; but it was nearly a century and a half afterwards that a Silesian peasant, Priessnitz, introduced, with wonderful success, a variety of operations with cold water, the most important of which was the packing the patient in a wet sheet, a process which after a time is followed by profuse sudation. Large establishments for carrying out this mode of bathing and its modifications have within the last thirty years been erected in many places on the Continent and in Great Britain, and have enjoyed a large share of popularity.

But the greatest and most important development of ordinary baths in modern times has taken place in England, and has been extending gradually to the Continent. The English had long used affusion and swimming baths freely in India. Cold and hot baths and shower baths have been introduced into private houses to an extent never known before; and, from 1842 downwards, public swimming baths, besides separate baths, have been supplied to the public at very moderate rates, in some cases associated with wash-houses for the poorer classes. Their number has increased rapidly in London, and in the principal Continental cities. Floating baths in rivers, always known in some German towns, have become common wherever there are flowing streams. The better supply of most European cities with water has aided in this movement. Ample enclosed swimming baths have of late years been erected at many sea-side places. When required, the water, if not heated in a boiler, is raised to a sufficient temperature by the aid of hot water pipes or of steam; and gas has been utilized for heating small quantities of water for baths in private houses. As to separate baths they used to be of wood, painted; they are now most frequently of metal, painted or lined with porcelain enamel. The swimming baths are lined with cement, tiles, or marble and porcelain slabs; and in some of the newest baths a good deal of ornamentation and painting of the walls and ceiling of the apartments, in imitation of the ancients, has been attempted.

We have thus traced in outline the history of baths through successive ages down to the present time. The medium of the baths spoken of thus far has been water, vapour, or dry hot air. But baths of more complex

nature, and of the greatest variety, have been in use from the earliest ages. The best known media are the various mineral waters and sea-water. These, and baths impregnated with their gases, cannot here be considered in detail; we can do little more than enumerate a few of the artificial baths. Of baths of *mineral* substances, those of sand are the oldest and best known; the practice of *arenation* or of burying the body in the sand of the sea-shore, or in heated sand near some hot spring, is very ancient, as also that of applying heated sand to various parts of the body. Within the last few years establishments have been introduced into various European cities where hot dry sand is methodically applied. Baths of *peat* earth are of comparatively recent origin, and are little used out of Germany. The peat earth is carefully prepared and pulverized, and then worked up with water into a pasty consistence, of which the temperature can be regulated before the patient immerses himself in it.

There are various baths that may be termed *chemical*, in which chlorine or nitromuriatic acid is added to the water of the bath, or where fumes of sulphur are made to rise and envelop the body.

Of *vegetable* baths the number is very large Leys of wine, in a state of fermentation, have been employed. An immense variety of aromatic herbs have been used to impregnate water with. Of late years fuci or sea-weed have been added to baths, under the idea of conveying into the system the iodine which they contain; but by far the most popular of all vegetable baths are those made with an extract got by distilling certain varieties of pine leaves. They are pleasant and stimulating.

The strangeness of the baths of *animal* substances, that have been at various times in use, is such that their employment seems scarcely credible. That baths of milk or of whey might be not unpopular is not surprising, but baths of blood, in some cases even of human blood, have been used; and baths of horse dung were for many ages in high favour, and were even succeeded for a short time by baths of guano.

Electrical or *galvanic* baths have been popular of late years, in which galvanic action is communicated to the patient while in baths

Baths also of *compressed air*, in which the patient is subjected to the pressure of two or three atmospheres, have been in use at certain places for some years.

A *sun* bath (*insolatio* or *heliosis*), exposing the body to the sun, the head being covered, was a favourite practice among the Greeks and Romans. This list of artificial baths might be readily increased.

We have hitherto spoken of general baths, but there are many varieties of local ones, the use of which has become somewhat more definite than it used to be, before the principles of hydropathy were understood. Some of these are affusion, half-baths, full baths, sitz baths, wave baths, local baths, shower and spray baths, douches, fomentations, injections, wrapping up in the wet sheet Some of these processes, though by no means of novel origin, require a few words of explanation.

Douches were used by the ancients, and have always been an important mode of applying water to a circumscribed portion of the body. They are, in fact, spouts of water, varying in size and temperature, applied with more or less force for a longer or shorter time against particular parts. A douche exercises a certain amount of friction, and a continued impulse on the spot to which it is applied, which stimulate the skin and the parts beneath it, quicken the circulation of the capillaries, and thus favour the absorption of abnormal deposits. It wakes up the slumbering activity of the tissues and helps to remove congestions from the deeper seated organs. The effects of the douche are so powerful that it cannot be applied for a long time continuously. After every two or three minutes there should be an interval in its use. It is obvious that a douche is capable of many local applications, on the description of which it is here impossible to enter. Nor need we say that the douche must be used with great care in the case of nervous and excitable people, and better not at all when any irritation or inflammation is present. Douches are invaluable in old neuralgias, in the sequelæ of rheumatism, and in thickened joints.

The alternation of hot and cold douches, which for some unknown reason has got the name of *Ecossaise*, is a very powerful remedy from the strong action and reaction which it produces, and is one of very great value. The shower bath may be regarded as a union of an immense number of fine douches projected on the head and shoulders. It has been long in use in England, and produces a strong effect on the nervous system. An ingenious contrivance for giving circular spray baths, by which water is propelled laterally in fine streams against every portion of the surface of the body, is now found in most establishments.

To all these modes of acting on the cutaneous surface and circulation must be added dry rubbing, as practised by the patient with the flesh glove, but much more thoroughly by the bath attendants, if properly instructed.

Action of Baths on the Human System.—We shall now inquire shortly into the theory of the operation of the baths and of the bathing processes, of which we have briefly traced the history.

The primary operation of baths is the action of heat and cold on the cutaneous surfaces through the medium of water.

The first purpose of baths is simply that of abstersion and cleanliness, to remove any foreign impurity from the surface, and to prevent the pores from being clogged by their own secretions or by desquamations of cuticle. It need scarcely be said that such objects are greatly promoted by the action of the alkali of soaps and by friction; that the use of warm water, owing to its immediate stimulation of the skin, promotes the separation of sordes; and that the vapour of water is still more efficient than water itself.

It has been supposed that water acts on the system by being absorbed through the skin. The question has been frequently discussed; but the great majority of observers believe that, under ordinary circumstances, no water is absorbed, or if any, so minute a quantity that it is not worth considering. And further, as we have alluded to medicated baths, it is proper to say that, according to the latest authorities, no foreign bodies, under the ordinary circumstances of a bath, are absorbed into the system; although when a portion of skin has been entirely cleared of its sebaceous secretion, it is possible that a strong solution of salts may be partially absorbed. In the case of medicated baths we therefore only look (in addition to the action of heat and cold, or more properly to the abstraction or communication and retention of heat) to any stimulant action on the skin which the ingredients of the bath may possess.

The powerful influence of water on the capillaries of the skin, and the mode and extent of that operation, depend primarily on the temperature of the fluid; for the influence of the mechanical pressure on the body of the water of a bath, which has been calculated at nearly one pound on each square inch of the surface, has never been accurately determined. Baths have therefore to be considered according to their temperature; and the effects of cold and of hot baths have to be studied. But we may as well first point out one or two general facts. The human system bears changes of temperature of the air much better than changes of the temperature of water. While the temperature of the

air at 75° is perhaps too warm for the feelings of many people, a continued bath at that temperature is felt to be cold and depressing. Again, a bath of 98° to 102° acts far more excitingly than air of the same temperature, both because, being a better conductor, water brings more heat to the body, and because it suppresses the perspiration, which is greatly augmented by air of that temperature. Further, a temperature a few degrees below blood heat is that of indifferent baths, which can be borne longest without natural disturbance of the system.

Cold baths act by refrigeration, and their effects vary according to the degree of temperature. The effects of a cold bath, the temperature not being below 50°, are these:—there is a diminution of the temperature of the skin and of the subjacent tissues; the blood at first rises in temperature nearly 4°, but soon subsides again, this diminution of temperature of the blood usually not taking place in the bath, but shortly after leaving it. There is a certain feeling of shock diffused over the whole surface, and if the cold is intense it induces a slight feeling of numbness in the skin. It becomes pale and its capillaries contract. The further action of a cold bath reaches the central nervous system, the heart and the lungs, as manifested by the tremor of the limbs it produces, along with a certain degree of oppression of the chest and a gasping for air, while the pulse becomes small and sinks. After a time reaction takes place, and brings redness to the skin and an increase of temperature.

The colder the water is, and the more powerful and depressing its effects, the quicker and more active is the reaction. Very cold baths, anything below 50°, cannot be borne long. Lowering of the temperature of the skin may be borne down to 9°, but a further reduction may prove fatal. The diminution of temperature is much more rapid when the water is in motion, or when the bather moves about; because, if the water is still, the layer of it in immediate contact with the body gets warmed to a certain degree.

The effects of *hydropathy* depend on the power of abstracting heat from the body, and of stimulating it by the application of cold water. The action is depressing or exciting, according as the withdrawal of heat or the stimulation predominates.

A great deal depends on the form of the bath; thus one may have -(1.) Its depressing operation,--with a loss of heat, retardation of the circulation, and feeling of weariness, when the same water remains in contact with the skin, and there is continuous withdrawal of heat without fresh stimulation. This occurs with full or sitz baths, with partial or complete wrapping up the body in a wet sheet which remains unchanged, and with frictions practised without removing the wet sheets. (2.) Its exciting operation,—with quickening of the action of the heart and lungs, and feeling of glow and of nervous excitement and of increased muscular power. These sensations are produced when the layer of water next the body and heated by it is removed, and fresh cold water causes fresh stimulus. These effects are produced by full baths with the water in motion used only for a short time, by frictions when the wet sheet is removed from the body, by douches, shower baths, bathing in rivers, &c. The depressing operation comes on much earlier in very cold water than in warmer; and in the same way the exciting operation comes on faster with the colder than with the warmer water. The short duration of the bath makes both its depressing and its exciting action less; its longer duration increases them; and if the baths be continued too long, the protracted abstraction of animal heat may prove very depressing.

We shall not attempt to give more than those few hints about hydropathic processes, and shall merely remark that under them the system is subjected to alternate periods of excitement and of rest. There is persistent lowering of the temperature of the body, with contraction of the capillaries and local anæmia. This is succeeded by the reverse, or by local hyperæmia. There is powerful excitement of the vascular and nervous systems. The processes of absorption and of excretion are stimulated. There is a great increase of perspiration. The transformation of tissue is materially quickened.

We must next consider the operation of warm baths of different temperatures.

Tepid, 85° *to* 95°.—The effects of a bath of this temperature are confined to the peripheral extremities of the nerves, and are so slight that they do not reach the central system. There is no reaction, and the animal temperature remains unchanged. Baths of this kind can be borne for hours with impunity.

Warm baths from 96° *to* 104°.—In these the action of the heat on the peripheral surface is propagated to the central system, and causes reaction, which manifests itself in moderately increased flow of the circulating fluids to the surface, and in an increased frequency of pulse. It appears to supply a slight stimulus to the renewal of tissue.

With a *hot bath* from 102° up to 110° the central nervous and circulating systems are more affected. The frequency of the pulse increases rapidly, the respiration becomes quickened, and is interrupted by deep inspirations. The skin is congested, and the retained animal heat bursts out, causing a profuse perspiration.

Very hot bath.—Everything above 110° feels very hot; anything above 120° almost scalding. Baths of from 119° to 126° have caused a rise of 2° to 4½° in the temperature of the blood. Such a bath can only be borne for a few minutes. It causes violent reflex action on the heart and the arterial system, excessive congestion of the skin, and violent perspiration.

In the use of hot baths a certain amount of vapour reaches the parts of the body not covered by the water, and is also inhaled.

Vapour baths produce profuse perspiration, and act in cleansing the skin, as powerful hot water baths do. Vapour, owing to its smaller specific heat, does not act so fast as water on the body. A vapour bath can be borne for a much longer time when the vapour it not inhaled. Vapour baths can be borne hotter than water baths, but cannot be continued so long, as vapour, being a bad conductor, prevents radiation of heat from the body. A higher heat than 122° is not borne comfortably. The vapour bath, though falling considerably short of the temperature of the hot air bath, heats the blood considerably more.

Hot air baths differ from vapour baths in not impeding the respiration as the latter do, by depositing moisture in the bronchial tubes. The lungs, instead of having to heat the inspired air, are subjected to a temperature above their own. Hot air baths, say of 135°, produce more profuse perspiration than vapour baths. If very hot, they raise the temperature of the body by several degrees.

Vapour baths, hot air baths, and many hydropathic processes agree in producing violent sudation, and also frequently in subjecting the body, while in a state of perspiration, to the action of water of a comparatively low temperature. Of perspiration we shall only say, that it is sensible and insensible: 30 oz. may be considered to be about its average amount in the twenty-four hours; of this, which is chiefly water, about ⅓ of an oz. consists of urea and of other peculiar substances. A man has been known to lose 3 lb in a Russian bath, some think more may be lost. As perspiration eliminates water and effete matter from the system, and also aids in respiration, it is obvious that its regulation must have an important effect on the economy.

In comparing the general effects of hot and cold baths, it

may be said that while the former tend to check cutaneous transpiration, the latter favour it. It is supposed, but is scarcely proved, that cold baths, by the stimulus they give, increase the reaction of the gastric and other fluids of the stomach, and of the alimentary canal, and that warm baths rather serve to retard it. Either hot or cold baths, but especially the latter, favour the secretion of urine. Whether warm or cold baths, like the breathing of hot or cold air, have any effect on the exhalation of carbonic acid has not been determined.

The warm bath causes swelling and congestion of the capillaries of the surface in the first instance; when the stimulus of heat is withdrawn their contraction ensues. A cold bath, again, first causes a contraction of the capillaries of the surface, which is followed by their expansion when reaction sets in. A warm bath elevates the temperature of the body, both by bringing a supply of heat to it and by preventing the radiation of heat from it. It can be borne longer than a cold bath. It draws blood to the surface, while a cold bath favours internal congestions. There is in both cases increased oxidation or waste of the tissues; but with the warm bath there is less call made on the system, as oxidation depends chiefly on increased heat, which in the case of the warm baths is artificially supplied. The reason why a man when much exhausted feels a hot bath refreshing, while he cannot bear a cold one, may be that the increased heat conveyed to him by the warm bath helps the process of oxidation, and thus relieves his system. Cold refreshes by exciting the functions, heat by physically relieving their action; a hot bath calms by reducing the loss of heat, and by supplying a certain amount of it. Very hot baths, it is true, act like cold baths, as stimulants to the heart and nervous centres; but they do it more gradually and with less shock to the system than cold baths. The general result of this comparison would show that warm are a milder remedy than cold baths, and are applicable often when the system does not possess power of reaction sufficient to make the use of the latter expedient.

As regards the use of baths simply for the promotion of health, it follows, from what has been stated, that warm baths are best suited for the delicate, for the very young, and for the old; cold baths for the strong and active, in whom the powers of reaction are unimpaired. It would be out of place to say much here about the use of baths in medicine. Warm baths according to their degree of heat are of great value in relaxing spasms, in calming the nervous system, and in neuralgias, chronic rheumatism, and gout. Turkish baths are useful in these last affections, and wherever it is of importance that there should be free action of the skin. Cold baths, again, are more useful when the system requires tonics, and when it can bear the shock of cold affusion; when diseases of the system, especially of the nervous system, are more functional than organic. It is obvious that the cold-water cure, including, as it does, copious sudation, combines in a certain degree the effects of both kinds of baths.

But baths often produce injurious effects when used injudiciously. Long continued warm baths are soporific, and have owing to this action often caused death by drowning. The effects of very hot baths are swimming in the head, vomiting, fainting, congestion of the brain, and, in some instances, apoplexy.

The symptoms seem to point to paralysis of the action of the heart. It is therefore very evident how cautious those should be, in the use of hot baths, who have weak hearts or any obstruction to the circulation. Fat men, and those who are full-blooded or predisposed to epilepsy, should avoid them. Protracted indulgence in warm baths is relaxing, and has been esteemed a sign of effeminacy in all ages. Sleepiness, though it will not follow the first immersion in a cold bath, is one of the effects of protracted cold baths; depression of the temperature of the surface that exceeds 9° becomes dangerous. The risk in cold baths is congestion of the internal organs, as often indicated by the lips getting blue. Extremely cold baths are, therefore, very unsafe wherever there is a tendency to internal congestion; and they are always dangerous when the system is exhausted by fatigue.

We shall conclude with a few words of advice about ordinary bathing for hygienic purposes:—Wherever it is practicable, bathing should be over before 1 p.m. It is not to be thought of when the stomach is loaded, or after much wine. The shorter the bath is, especially if the water be cold, and the bather cannot swim, the better,—say five minutes. He should swim if possible, and then a quarter of an hour is long enough. Bathing should not be practised more than once a day. When one is over-heated, but not exhausted, it is advisable to bathe at once, without waiting to cool. After hot air or vapour baths care must be taken that cold be not caught, although the more enthusiastic advocates of such baths declare that there is no risk of this.

For the literature of baths in earlier periods we would refer to the *Architecture* of Vitruvius, and to Lucian's *Hippias*; to A. Baccius, *De Thermis Veterum* (in Grævii *Thesaur. Antiquitat. Roman.*, 1694, vol. xii.); to Cameron's *Roman Baths*, London, 1772; to Gell's *Pompeiana*, London, 1836; to Bechi, *Museo Borbonico*, ii. 49–52; to Becker's *Gallus*, and to the article "Balneæ" by Rich, in Dr Smith's *Dictionary of Greek and Roman Antiquities*. Some of the more important works on the use of water externally are those of Floyer, *Enquiry into the Right Use of Water*, London, 1697; F. Hoffman, *De Aqua Medicina Universali*, Halle, 1712; Lucas, *Theory and Use of Baths*, Dublin, 1772; James Currie, *Medical Reports on the Effects of Water*, Liverpool, 1788; Marcard, *Ueber die Natur und die Gebrauch der Bader*, Hanover, 1793. Some of the best works on Hydropathy are those of E. Johnson and Petri, and the very complete *Manuals* of Fleury and of Beni Barde. There are many separate brochures on Turkish baths by Urquhart, Brereton, Haughton, Barter, Bartholomew, Luther, and a separate work by Sir John Fife. A considerable amount of information regarding bathing may also be found in Dunlop's *Philosophy of the Bath*. (J. M.)

BATHURST, a town of New South Wales, on the Macquarie River, 122 miles W.S.W. of Sydney, with which it is connected by railway. It stands in a fertile plain on the western side of the Blue Mountains, and is the centre of an important gold field. Founded in 1815 by Governor Macquarie, and named in honour of Lord Bathurst (the third earl), it soon became a place of considerable size, and was raised to the rank of a municipality in 1862. It is built in rather a spacious style, with broad and regular streets running at right angles. Many of the buildings are large and handsome; and it possesses numerous churches and schools, a theatre, a hospital, and various societies. Population in 1871, 5030.

BATHURST, Allen Bathurst, Earl of, a distinguished statesman in Queen Anne's reign, was born in the year 1684. After completing his education at Cambridge, he was elected in 1705 to represent the borough of Cirencester. He distinguished himself particularly in the struggles and debates relative to the union of England and Scotland, firmly supporting a measure which he thought calculated to strengthen the Government and add to the prosperity of the country. Though he was content to act a subordinate part in the opposition planned by Harley and St John, his intimate friends, in order to sap the credit of the duke of Marlborough and his adherents, nevertheless he did good service to his party by arraigning, with more eloquence than truth, the conduct of the general and of the earl of Godolphin, whom he accused of lavishing the treasures of the nation on conquests more splendid than serviceable The loss of the battle of Almanza, which happened about this time, seconded his efforts and those of his associates in dispelling what they called the intoxication of former successes, and disparaging achievements which

reflect immortal honour on the British name. But his personal regard for Lord Somers, president of the council, suffered no abatement, although they were of different opinions in politics; and when Somers was deprived of office, Bathurst acted with such tenderness and delicacy as to preserve his esteem in a private station. In consideration of his zeal and services, the queen, in 1711, advanced him to the peerage by the title of Baron Bathurst, of Battlesden, in Bedfordshire. In the Upper House he distinguished himself by impeaching the directors of the notorious South Sea scheme, and by resisting the bill brought in against Atterbury. He was a determined opponent of Sir Robert Walpole; and when, after an obstinate struggle, that minister was forced to resign his various posts, Lord Bathurst was sworn of the privy council, and made captain of the gentlemen pensioners, an office which he resigned in 1744. In 1757 he was appointed treasurer to George III. (then Prince of Wales), and continued in the list of privy councillors at that monarch's accession to the throne; but, on account of his advanced age, he declined to take any further part in politics.

Lord Bathurst was not less distinguished as a patron of literature than as an active statesman. Congreve, Vanburgh, Swift, Prior, Rowe, Addison, Pope, Arbuthnot, Gay, and most of the men of genius of his own time, cultivated his friendship, and were proud of his correspondence. Pope, in his *Epistle on the Use of Riches*, which is addressed to Lord Bathurst, compliments his friend in some highly characteristic lines. Sterne also speaks of him in terms of affectionate admiration. He received further elevation to an earldom in 1772, and lived to see his second son Henry promoted to the peerage by the title of Baron Apsley, and several years lord high chancellor of Great Britain. By his marriage with Catherine, daughter of Sir Peter Apsley, Lord Bathurst had four sons and five daughters. He died after a few days' illness, at his seat near Cirencester, September 16, 1775, in the ninety-first year of his age.

BATHURST, RALPH, uncle of the preceding, was born in the year 1620. He studied divinity in Trinity College, Oxford; but, on the breaking out of the civil war, he changed the course of his studies, and, applying himself to medicine, took the degree of doctor in that faculty. By dint of assiduous application, he soon rose to eminence in his profession; and in the time of the Commonwealth was appointed physician to the state. At the Restoration, however, he quitted the practice of physic; was elected a fellow of the Royal Society, and president of his college; and, having entered holy orders, was made chaplain to the king, and afterwards dean of Wells. Soon after, he filled the office of vice-chancellor of Oxford, and was nominated by King William and Queen Mary to the see of Bristol; but this honour he declined. To the accomplishments of an orator, philosopher, and poet, he added an inexhaustible fund of wit. Ridicule—of which he was an absolute master—was the weapon with which he used to correct the delinquents of his college. His poetical pieces in the *Musæ Anglicanæ* are excellent of their kind; he wrote also several other poems, both in English and Latin. He died June 14, 1704, in his eighty-fourth year. (*Life and Remains*, by Th. Warton, 1761.)

BATHYCLES, a Greek sculptor, born at Magnesia on the Mæander, known for his sculptures on the throne of the statue of Apollo at Amyclæ near Sparta, which Pausanias saw and describes (iii. 18, 6). His date is uncertain, but cannot well be later than between 563–549 B.C. The statue itself existed before his time. For an attempt to reconstruct this throne see Brunn, *Rhein. Museum* (new series), vol. v. p. 325.

BATON-ROUGE, a town in the state of Louisiana, North America, situated on a bluff on the left bank of the Mississippi, 120 miles above New Orleans. It has a court-house, state penitentiary, national arsenal and barracks, military hospital, deaf and dumb asylum, and state university. Baton-Rouge was one of the first settlements of the French. In 1849 it was made the capital of the state, but has since given place to New Orleans. Occupied by the Federal troops after the capture of that city, it was defended in 1862 by General Williams against the attack of the Confederates under Breckenridge. Population in 1870, 6498.

BATONI, POMPEO GIROLAMO, a native of Lucca, who was regarded in Italy as a great painter in the 18th century, and who unquestionably did much to rescue the art from the intense mannerism into which it had fallen during the century preceding. His paintings, however, are not of the highest order of merit, though they are generally graceful, well designed, and harmoniously coloured. His best production is thought to be his group of Peace and War. Batoni painted an unusual number of pictures, and was also celebrated for his portraits. He was born in 1708, and died at Rome in 1787.

BATOUM. See BATUM.

BATRACHUS, according to Pliny (xxxvi. 42), the name of a Greek architect who, along with Sauras (both natives of Sparta), was employed by Metellus in the construction of certain temples in Rome. The story goes that, being forbidden to inscribe their names on the buildings, these two architects gained their end by placing the figures of a frog (*batrachos*) and a lizard (*saura*) on the base of the columns. But it is possible that the fanciful use of such figures for ornament in later times may have led to the invention of both the names.

BATTALION is the tactical unit of infantry. It is the term applied to the most numerous body of dismounted men which one commanding officer can personally superintend. It consists of from four to ten companies, is always commanded by a field officer, and has a normal war strength of about 1000 men. Two or more battalions constitute a regiment; two or more regiments a brigade; two or more brigades a division; two or more divisions a *corps d'armée*; and two or more *corps d'armée* an army. In the British service, however, there are several regiments consisting of but one battalion. See ARMY.

BATTAS, a people in the northern portion of Sumatra, which regards itself as the oldest in the island, and is distinguished by a pertinacious adherence to ancient customs. The Batta is of middle height, his colour is a light brown, and his hair is black and is worn long. He is dirty in his dress and dwelling, and eats any kind of food that presents itself, though he lives chiefly on rice. A little iron-work, earthenware, and cloth constitute the only industrial products of the tribe. The houses are of wood, roofed with palm-leaf ribs; and the villages are defended by earthen walls and bamboo palisades. The people show a very peaceful disposition, but are valorous when occasion demands. Cannibalism is practised.

Batta or Batak Language.—Up to the publication of Dr H. N. van der Tuuk's essay *Over schrift en uitspraak der Tobasche taal* (1855), the first fruits of an eight years' residence amongst the Battas, our knowledge of the Batak language was confined to lists of words more or less complete, chiefly to be found in Marsden's *Miscellaneous Works*, in Junghuhn's *Battàlander*, and in the *Tijdschrift van het Bataviaasch Genootschap*, vol. iii. (1855). By his exhaustive works (*Bataksch Leesboek*, in 4 vols., 1861–2; *Bataksch-nederduitsch Woordenboek*, 1861; *Tobasche Spraakkunst*, 1864–7) that eminent Dutch savant has made the Batak language the most accessible of the various tongues spoken in Sumatra. According to him, the Batak language is nearest akin to the old Javanese and Tagal, whereas a recent writer (A. Schreiber, *Die Battas in ihrem Verhältniss*

zu den Malaien von Sumatra, 1874) has endeavoured to prove its closer affinity with the Malay proper. Like most languages spoken by less civilized tribes, the Batak is poor in general terms, but abounds in terms for special objects. The number of dialects is three, viz., the Toba, the Mandailing, and the Dairi dialects; the first and second have again two subdivisions each. The Battas further possess six peculiar or recondite modes of speech, such as the *hata andung*, or language of the wakes, and the *hata poda*, or the soothsayer's language. A fair acquaintance with reading and writing is very general among them. Their alphabet is said, with the Rejang and Lampong alphabets, to be of Indian origin. The language is written on bark or bamboo staves from bottom to top, the lines being arranged from left to right. The Batak literature consists chiefly in books on witchcraft, in stories, riddles, incantations, &c., and is mostly in prose, occasionally varied by verse. See on it the fourth volume of the *Batak Leesboek*, or *Reader*, above mentioned.

BATTERING RAM (*Aries*), a military engine used before the invention of gunpowder, for beating down the walls of besieged fortresses. It consisted of a long heavy beam of timber, armed at the extremity with iron fashioned something like the head of a ram. In its simplest form the beam was carried in the hands of the soldiers, who assailed the walls with it by main force. The improved ram was composed of a longer beam, in some cases extending to 120 feet, shod with iron at one end, and suspended, either by the middle or from two points, from another beam laid across two posts. This is the kind described by Josephus as having been used at the siege of Jerusalem (*B. J.*, iii. 7, 19). It was covered over with a roof, shell, or screen of boards (called the *testudo*) to protect the men employed in working it from the stones, darts, and other missiles discharged by the besieged from the walls. It was also provided with wheels, which greatly facilitated its operations. A hundred soldiers at a time, and sometimes even a greater number, were employed to work it, and the parties were relieved in constant succession. Josephus says that no wall could resist the continued application of the ram.

BATTERY is the tactical unit of artillery. It is the term applied to the largest number of fully equipped mobile guns which can be personally superintended by one man. Batteries may be divided into the four classes of *horse*, *field*, *mountain*, and *position* artillery batteries. In England, France, and Germany batteries consist of six guns; in Austria and Russia of eight guns each. The guns of horse field artillery are drawn by from four to eight horses, the usual number being six. Each battery has a certain number of men told off for the service of the gun called *gunners*, and others to manage the draught called *drivers*. In the horse artillery the gunners are mounted on horses, in field batteries they are carried on the limbers and waggons, in mountain and position batteries both gunners and drivers usually walk. Both horse and field batteries are recognized tactical units of an army, and are maintained in an efficient state in time of peace. Position batteries are organized generally in time of war, are possessed of the heaviest guns consistent with mobility, and are useful in certain special cases, such as the attack or defence of a fortified position, the bombardment of a town, &c. Mountain batteries consist usually of light guns mounted on the backs of mules, and are adapted solely for warfare in mountainous countries. See ARTILLERY. The term battery is also applied to the companies of dismounted artillerymen necessary to fight fortress and siege guns; to separate groups of guns in permanent works; and to the earthworks constructed for the protection of guns in siege operations.

BATTERY, as a law term, is the unlawful beating of another. See ASSAULT, vol. ii. p. 724.

BATTEUX, CHARLES, a French writer on philosophy and the principles of literature, was born near Vouziers in 1713, and died in 1780. In 1739 he came to Paris, and after having taught with success in the colleges of Lisieux and Navarre, was appointed to the chair of Greek and Roman philosophy in the College of France. In 1746 he published his treatise *Beaux Arts réduits à une même Principe*, in which he extended the Aristotelian definition of the art of poetry to art of all kinds. His *Cours de Belles-Lettres*, 5 vols., 1765, was afterwards included with some minor writings in the large treatise *Principes de la Littérature*, 1774. The rules for composition there laid down are, perhaps, too methodical and pedantic. His philosophical writings were *La Morale d'Epicure tirée de ses propres écrits*, 1758, and the *Histoire de Causes Premières*, 1769, a survey of the history of philosophy which is by no means devoid of merit. In consequence of the freedom with which he attacked in this work the abuse of authority in matters of philosophy, he was removed from his professorial chair. His last and most extensive work was a *Cours d'études à l'usage des élèves de l'école militaire*, 45 vols.

BATTICALOA, the chief town of a district in the Eastern Province of Ceylon, situated on an island in lat. 7° 44′ N. and long. 81° 52′ E. It is of importance for its haven and the adjacent salt lagoons. The inhabitants are principally natives; but there is a fort and an English settlement. Population of town, 3353, and of district, 93,220.

BATTLE, an engagement between two armies, as distinguished from the skirmishes, or minor actions, fought between their smaller sections. A battle is said to be general, where the whole, or the greater part, of each army is brought into action; and partial, where only brigades, divisions, or some corps d'armée out of several upon the ground, are engaged. However the numbers may vary, the great principles to be applied in delivering battle are at root in all ages the same. It is no doubt true that, in the circumstances under which battles are fought, there is nothing invariable; on the contrary, it is scarcely possible to suppose two cases alike in every particular, or even resembling each other in all their leading features. From the very nature of things, the minor data of the problem are variable; but the grand principles—those which depend on moral elements—continue immutably the same. On the other hand, the material elements which enter into the calculations of a general are constantly changing; and it is this circumstance which affords scope for the exercise of his genius, his sagacity, and his military science. But it would be manifestly absurd to maintain that, because the lesser conditions are so frequently altered, the great principles of the art are changed with them. The issue of battle is indeed always uncertain,—because the calculations of the general may be defective, his combinations unscientific, his foresight limited, or his temperament rash and impetuous; and because, even where none of these causes of failure exist, events which no human sagacity could have divined or provided against may occur to defeat the wisest plans. But all this implies that if every contingency could have been foreseen and properly met, the result would not have been doubtful, and that the grand chances are always on the side of him who, being provided with sufficient means for his end, forms his plan with the greatest sagacity, and executes it with corresponding vigour and ability. For, variable as the results of battles appear, decisive success has in all ages followed the combinations of great commanders; and victory in the long-run has seldom failed to pay homage to science. And this is because those principles which science has established as universally applicable depend on certain fixed laws in

human nature, which ages have not changed since history was first written. That undisciplined forces, for example, are easily shaken by panic arising out of any such sudden disaster as the fall of their general, was as true in the day when Ahab, for this reason, disguised himself at Ramoth-Gilead as it is now. That infantry, thoroughly broken up and exposed on open ground, may be taken or destroyed by a very inferior number of cavalry, was illustrated no less by Hannibal at Cannæ than by Murat's charge round the allied right at Dresden. The feeling that there was no safe retreat open in case of disaster was as fatal to the Persians at Marathon as to the French at Leipsic. The crushing effect of heavy columns pressing against a line (which, as only the outer part of the column can act, is purely moral) was quite as conspicuous in the victory of Epaminondas at Mantinea as when Napoleon cut his enemy's centre through at Austerlitz. Above all, military history, from the earliest times, proves two facts of prime importance to commanders in every action: the one, that the best troops become unsteady when their flank is gained, just as a single man in a struggle desires to face fairly the adversary about to rush on him; the other, that a comparatively small body coming fresh into action with troops exhausted by the exertions and nervous tension of a battle, has an advantage over much larger numbers. And being thus fixed, these principles obviously yield certain general rules, to which every prudent commander of any age strives to conform. Circumstances may lead him to violate them, but the examples of Leipsic and Waterloo are there to prove that, even with the greatest of generals, the result may be ruinous. In the first case, the French were forced to fight with their backs to a river; in the second, by a combination they were not prepared for their flank was struck by the Prussians when they were fully engaged with Wellington in front; and total defeat ensued in both.

A battle is not only the most imposing, but also the most important event in war. It is the consummation to which all previous combinations necessarily tend; it is that grand act which may decide the fate of empires as well as armies. The highest and dearest interests of nations, nay, even of humanity itself, may be involved in its issue. It cannot, therefore, be uninstructive to look briefly at the theory of those received principles by the skilful application of which the fate of battles has in all ages been determined.

All the methods in which a battle can be fought may be reduced to three for abstract purposes, each governed by a distinct principle. The first, the purely defensive, consists in waiting for the enemy, in a position chosen for the purpose, the object being simply that of maintaining it successfully against him. Theorists almost universally condemn this, and that with good apparent reason; for there is something peculiarly trying to the moral endurance of even the best troops in feeling that they are pinned to one spot to await the assaults of the enemy without any prospect of retaliation. But the rule is not without exceptions, as is plainly proved by comparing the two great examples of purely defensive actions fought during the campaigns of 1862–63 in America,—Fredericksburg and Gettysburg. The defender in each case was perfectly successful, beating off his assailant with tremendous loss; but the results were very opposite. Lee's victory at Fredericksburg stopped, indeed, the advance upon Richmond for the time, but did not seriously affect the course of the war. Meade, on the other hand, by beating the Confederates off at Gettysburg, completely turned the tide of the campaign, and compelled Lee to abandon all idea of invading the North and commence a difficult retreat to Virginia; while thenceforth Washington was saved from all danger of being separated from the states that supported the union. This was because the position maintained at Fredericksburg was no more than one point on a single line of advance direct upon Richmond, whereas that of Gettysburg was so completely the key to the whole of the campaign of Maryland, that, whilst it was held by Meade, it was impossible for Lee to advance beyond it or any part of the north-eastern states. The failure to carry it therefore paralyzed the whole scheme of the Confederates for transferring the burden of the struggle to hostile soil. And from a comparison of the varying consequences of these actions, so similar in their course, it will be seen that the defensive battle is justified only when the position to be maintained is one of vital consequence for the enemy to seize in order to carry on further operations with success. Lee has been fairly condemned by even friendly critics for not turning his defensive attitude at Fredericksburg into an offensive on the repulse of the enemy's attack. No one blames Meade for the like conduct at Gettysburg, because his holding his ground fully accomplished all that it was necessary for him to do. But such an instance as this last, it should be added, can but rarely occur.

The second system is the entirely offensive,—in plain words, the attacking the enemy wherever found, with all force available. As it carries with it the moral power which in all ages is found to accompany, until some decided check occur, bodies of disciplined men moving freely forward to the assault, and as it gives the leader the power of choosing the weaker points of his adversary's line on which to concentrate his blows, so it has ever been the favourite with bold and skilful generals leading good troops. Frederick and Napoleon alike preferred it, and won some of their chiefest victories by using it freely. Wellington employed it with marked success in the latest phases of the Peninsular War in 1813–14. Grant adopted it avowedly in his great struggle with Lee in Virginia in 1864. And the Prussians fought on this principle throughout the two great wars of 1866 and 1870–71. History, however, shows that it is only fully justified when the attacking general has a force decidedly superior either in numbers or in moral power; or when, as in the famous case of Frederick at Leuthen, he possesses such extraordinary skill in manœuvring as to give him all the advantages of long odds, although engaged against superior numbers. It has the serious defect that if the defence prove more successful than was expected, the assailant may have to bring up successively and exhaust all his forces, and thus leave himself without any reserve to meet a sudden onset from the opposite side. In such case defeat probably entails the complete wreck of the hitherto offensive army, and with it possibly the loss of the campaign.

It is for this reason that prudent commanders are wont, where the choice lies with them, to select the third mode, the defensive-offensive, or a combination of the two preceding. This consists in taking up a position with the design of awaiting the adversary's attack on it, but also of watching the opportunity afforded by the exhaustion of his army in its assaults, or by his extending it too widely in choosing the best points from which to make them, in order to pass suddenly to the offensive. Wellington is justly famous for the success with which he employed this form of action. But it is one of the highest tests of generalship to know exactly when most fitly to use either. And as Napoleon won three at least of his most striking victories,—Marengo, Austerlitz, and Dresden,—by passing at the right moment suddenly from an apparently passive attitude of defence to a vigorous offensive, so Wellington, after all the world had come to regard him as great only on the defensive, used the strictly offensive form, with the like success, at Vitoria, Orthez, and Toulouse, the last of these three actions being one of such apparent temerity as can hardly be paralleled in modern history, and yet perfectly

justified by his instinctive knowledge of the demoralized state of the enemy whose position he undertook to force. Marlborough, who as a fighter of great battles has never been surpassed, and who, like Wellington, led a mixed army of English and allies, appears to have always had a decided preference for the offensive;—so little does nationality supply any just rule for selecting either. Marlborough's choice, in all probability, was adopted from the comparatively passive attitude of his various adversaries at Blenheim, Ramillies, and Malplaquet, which tempted a bold offensive on his part. Lee, though certainly addicted to the strictly defensive, which was suited to his inferiority of numbers and to the strong nature of the ground he usually occupied, had the true instinct (as was especially shown in his great victory at Chancellorsville) of seizing any special opportunity offered by the carelessness of an adversary who brought against him apparently overwhelming forces. And in the late war, although the German generals elsewhere continually took that bold offensive which was justified at first by superior numbers, and later by the increasingly high spirits of their troops, yet in the most important and bloodiest action of the whole, Mars-la-Tour, they were content, after it had been well begun by their own attack, to pass to the completely defensive,—it being evident that by merely maintaining the position they had taken up across the French line of retreat from Metz, all the immediate advantage possible from victory would be won.

On the whole, therefore, it may be affirmed that no theory is sound which prescribes or forbids the use of any of the three methods, or lays down strict rules for the application of any of them. Defence is, however, the natural attitude of the weaker party, as Clausewitz, the greatest of all theoretical writers on war, has carefully pointed out. Under what conditions it is to be accepted, or how long adhered to when once assumed, are problems which it requires true genius to grapple with successfully; for they can only be solved rightly according to the circumstances of the hour, perhaps of the moment. To see a crucial instance illustrated by a failure, we may look at Gravelotte. There Bazaine was forced by the case to fight on the defensive. An opportunity occurred in the day, on the decided repulse of the German right-wing under Steinmetz, of striking such a counterblow as, from Napoleon's hand, would probably have forced a victory over even the great odds possessed by the German commander. But Bazaine had no spark of the instinctive genius needed. He lost the opportunity, and with it the battle,—the loss entailing the last hope of rescuing his host from the dangerous and indeed ignominious position in which previous errors of judgment had placed it.

In conclusion, in order to demonstrate the undying truth of the main principle of battle, which is that, the general conditions being equal, the moral advantage is invariably at the outset with the offensive rather than the defensive,—with the army that feels itself moving forward rather than that which stands still,—it is well to refer to the recent discussion on the effect of breech-loading arms. It was almost universally assumed by theorists, especially by those of Prussia herself, when she first put the needle-gun into her soldiers' hands, that the power of the new weapon would be most perceptible in defence, for which its more rapid fire seemed so specially adapted. The Prussian instructions, drawn up before 1866, avowedly followed this view. Those who compiled them overlooked the fact that the moral power of the weapon would of itself tend to carry those who bore it forward, and add an additional advantage to those the assailant had before in his greater show of vigour and activity, and his power of searching out the weaker parts of his enemy's position and throwing his troops in force upon them. History has reversed the Prussian theory, and proved afresh how powerful for victory is the moral element in the soldiers' character. For, out of the opening events of 1866, and the vast encouragement the Prussians experienced in their first collisions with Benedek's army, has been evolved the most audacious and aggressive series of actions any nation ever fought. Certain Prussian writers have since the war of 1870–71 gone almost to the opposite extreme, and claimed absolute superiority for the offensive under all circumstances, forgetting that, against a stronger army, or even one perfectly equal in all other respects and well posted, it must inevitably be as dangerous as it proved when confidently tried by Napoleon's marshals against British troops under Wellington.

The various so-called "orders of battle" of which theoretical writers treat, believing that they see a close similarity in the dispositions of well-led armies from the days of the Grecians down to our own, are, so far as such similarity really exists, founded entirely on one or other of the moral elements already mentioned, above all, on the desire to gain the enemy's flank. The late General Winfield Scott, one of the few commanders who could boast that he had more than once seen the back of English infantry in fair fight, declared that this desire is so instinctive that it is impossible to array two bodies of disciplined troops against each other without one at least soon striving for this advantage. But so far as this and other like universal principles are applied to the actual drawing up of an army at any period in a special order of battle, the arrangements must in practice vary with the arms and discipline. This subject, in fact, forms part of that special art which treats of the handling of troops in the presence of the enemy, and falls under the head of "tactics," for which see the article WAR. The mechanism of battles must vary continually; the great leading principles we have spoken of cannot change.

BATTLE, a market-town in the county of Sussex, on the South-Eastern Railway, 56 miles from London. It is situated in a valley, and consists of one street. Its name is derived from the conflict in 1066, which insured to William the Norman the crown of England. The abbey founded by him forms a most magnificent pile of ruins, and the ancient gatehouse is still in good preservation. The place is now celebrated for its gunpowder manufactories. Population of the parish in 1871, 3495.

BATTUS, the founder of the Greek colony of Cyrene in Libya, whither he had been directed by the oracle at Delphi (about 650 B.C.) The Greeks who accompanied him were, like himself, natives of Thera (Santorin), and partly descended from the race of the Minyæ. The origin of the colony as told in Thera (*Herodotus*, iv. 150) was as follows:—

Grinus, king of that island, had gone attended by Battus and others to consult the oracle at Delphi, and was told by it to "found a city in Libya." They knew not where Libya was, and could take no action. Seven years after there fell a drought on Thera, and the oracle, being again questioned, repeated the command to found a town in Libya. Messengers were now sent to Crete to see if any one there knew where this district was. They met a fisherman, Corobius, who said that he had once been driven to Platea, an island of Libya, whither he agreed to conduct them. To make sure, they went with him; and having landed on Platea, they again, leaving Corobius there with provisions for some months, returned to Thera to collect colonists, of whom as many as two 50-oared galleys could convey set out with Battus as their leader. In Cyrene itself, however, a different story of the origin of the colony was told. Etearchus, it was said, king of Axus in Crete, having married a second wife, who persuaded him to get rid of Phronime, the daughter of his first wife, agreed with a merchant from Thera that he should take her in his ship and let her down into the sea. The merchant, true to the letter of his bargain, let her down, but with a rope about her by which he drew her up again, and took her to Thera, where she married

Polymnestus, a descendant of the Minyæ, and bore him a son, who, because of his stuttering, was called Battus. On growing to manhood, Battus inquired at the oracle of Delphi about his voice, and when told to "found a town in Libya," was unable to understand the response. Afterwards, owing to misfortunes, the Theræans sent to Delphi for advice, and were again ordered to send a colony to Cyrene, under Battus, which they now did, landing first in Platea, and afterwards removing to Cyrene itself.

Herodotus (iv. 155) thinks that the name of Battus, being the word for "king" in Libya, had been applied to the leader of the colony after his arrival there, and that it had no reference to his stuttering. Battus having ruled forty years (about 630–590 B.C.) was succeeded by his son Arcesilaus, who, after a reign of sixteen years, of which nothing is known, was followed by Battus II. Of this dynasty, known as the *Battiadæ*, the names were alternately Battus and Arcesilaus, there being, as the oracle predicted, probably after the fact, four of each. Under Battus II., surnamed the Prosperous, the population of Cyrene was increased by a large number of colonists from all parts of Greece invited by a promise of land To find land for all it was necessary to dispossess many of the native Libyans, who therefore sought and obtained the aid of an Egyptian army, which, however was completely defeated. Amasis, the next king of Egypt, proved friendly to Cyrene. The reign of Arcesilaus II. (about 554–544 B.C.) is known only for the disastrous battle with the Libyans, who had been stirred to revolt by his brothers, in which he lost 7000 hoplites. He himself soon after fell ill, and was strangled by his brother Learchus. The disgrace of the ruling family being increased by the fact that the next heir, Battus III., was lame, the oracle at Delphi was consulted, and advised that affairs should be placed in the hands of Demonax of Mantinea, who distributed the people into three tribes, and arranged a form of self-government for them. Battus, retaining the royal lands and sacred offices of a king, acquiesced. Not so his wife Pheretime and son Arcesilaus, who bestirred themselves,—the former in Cyprus, the latter in Samos,—to raise forces to recover the sovereignty, and ultimately succeeded; but in his success Arcesilaus III. forgot the commands of the oracle (*Herod.*, iv. 163), and, among other cruelties to the vanquished, burned alive a number of them who had escaped to a tower. To avoid the consequences he retired to the town of Barca, but was there slain in the market-place by some fugitives from Cyrene. His mother, Pheretime, who had been regent in his absence, now obtained from Aryandes, the Persian satrap of Egypt, an army to take vengeance on the people of Barca After a fruitless siege of nine months (*Herod.*, iv. 200) a treaty of peace was solemnly sworn to by the Persian general, and was instantly broken in spirit, though not in letter, when the gates of Barca were thrown open. Pheretime, ruthless in her cruelties towards those who had been connected with her son's murder, herself died soon after, a wretched death, in Egypt Of Battus IV. nothing is known. Arcesilaus IV. with whom the dynasty ended (about 460–415 B.C.), obtained twice the victory in the chariot race at the Pythian games, and for this was celebrated by Pindar in two odes (*Pyth.*, iv and v.)

BATU, a thickly populated island lying off the north western coast of Sumatra, 40 miles in length by 10 in average breadth, almost immediately under the equinoctial line. Cocoa-nuts, oil, and trepang are exported. It is the seat of an active volcano The inhabitants are a colony from the island of Nias.

BATUM, a seaport town of Asiatic Turkey, in the pashalic of Trebizond, and 110 miles N.E. of the city of that name. It is situated on the Black Sea, not far from the mouth of the Chorak, and the harbour is the safest and most important on the eastern coast There is deep water close to the shore, and protection is afforded by the high overhanging cliffs of a spur of the Gouriel Mountains. The situation of the town is marshy and unhealthy; and the place itself is "filthy in the extreme." It is now the seat of a *mutessarif*, or deputy-governor; and the Turkish authorities are fortifying it with several strong batteries. A dilapidated *ronak*, or governor's house, two mosques, and a Greek church are almost the only buildings that relieve the meanness of the squalid-looking huts; but the natural and political position of the place render it of commercial and military importance. There is a custom-house, a Russian consulate, and a steamer agency; and the Russian steamers regularly use the harbour as a port of transshipment, their own harbour at Poti being insecure. A considerable contraband trade is carried on across the frontiers, as well as a moderate amount of regular exportation by sea. The population does not exceed 2000.

BAUDELAIRE, CHARLES, who would have been pleased to be considered as a master in the French Satanic school of poetry, was born at Paris in April 1821. He was the son of a man of some distinction, who had been the friend of Condorcet and of Cabanis. The poet's life contained no episode more important than a voyage to the East Indies, where he resided for some time, and whence he brought perhaps the Oriental languor and the curious delight in perfumes which make themselves felt in many of his verses. Baudelaire returned to Paris while still a very young man, and sought the literary, or at least what is called the Bohemian society of the capital. He admired M. Théophile Gautier, as M. Gautier had admired Victor Hugo, and his poems are all conceived in the school of Romanticism. Romanticism, or, to define it rather widely, the school of revolt against French academic taste, the search for remote experiences, the artistic reproduction of the excesses and vagaries of passion, found in Baudelaire its most reckless disciple. Some portions of his verses, *Les Fleurs du Mal*, appeared originally in the *Revue des Deux Mondes*, and when they were published in a volume, had the misfortune to attract the notice of the police. When so many low unwholesome works were published without scandal, it was an error to attract notice to the verses of Baudelaire. The chief notes of his poetry are a perverse delight in loathsome subjects, a curious reaction towards Christianity and repentance, a pleasure in the last refinements of art, above all an unsleeping self-consciousness and affectation. Less unpleasant than his *Fleurs du Mal* are his exquisite and gem-like *Petits Poemes en Prose*, and his volumes of subtle and ingenious criticism. Baudelaire died in 1867 at the age of forty-six, after a long illness. He will possibly be best remembered for his translation of the works of Edgar Allan Poe, one of the most accurate and brilliant translations in literature. The impression left on the reader by Baudelaire's life and industry is rather a painful one. It is difficult to be blind to the fact that he lived for notoriety, and that he preferred to gain notoriety by a distinguished activity in the least wholesome fields of letters. His poems represent the high-water mark of the tide of Romanticism; and it may be hoped that the taste for lepers and corpses in poetry will now gradually decline. The best edition of his works, prose and verse, is that published by Michel Levy, Paris Some of his suppressed poems were printed in Brussels, under the title *Les Épaves*.

BAUHIN, GASPARD, the son of an eminent French physician, who had to leave his native country on becoming a convert to Protestantism, was born at Basel in 1560. Early devoting himself to medicine, he pursued his studies at Padua, Montpellier, and some of the celebrated schools in Germany. In his journeys through various parts of Europe he collected a number of plants which had escaped his elder brother's notice. Returning to Basel in 1580, he was admitted to the degree of doctor, and gave private lectures

in botany and anatomy. In 1582 he was appointed to the Greek professorship in that university, and in 1588 to the chair of anatomy and botany. He was afterwards made city physician, professor of the practice of medicine, rector of the university, and dean of his faculty. He published several works relative to botany, of which the most valuable is his *Pinax Theatri Botanici, seu Index in Theophrasti, Dioscoridis, Plinii, et botanicorum qui a seculo scripserunt opera*, 4to. The confusion that began to rise at this time from botanical writers describing the same plant under different names rendered such a task highly necessary; and though there are many defects in the execution, the *Pinax* of Bauhin is still a useful key to all the writers before his time. Another great work which he planned was a *Theatrum Botanicum*, meant to be comprised in twelve parts folio, of which he finished three; only one however was published. He also gave a very copious catalogue of the plants growing in the environs of Basel, and edited the works of Matthiolus with considerable additions. He likewise wrote on anatomy; his principal work on this subject is *Theatrum Anatomicum infinitis locis auctum*, 4to, Frankfort, 1621, which is a kind of *pinax* of anatomical facts and opinions. He died in 1624.

BAUHIN, Jean, brother of the above, was born at Basel in 1541. He studied at Tubingen under the celebrated botanist Fuchs, and afterwards travelled with Conrad Gesner, and collected plants in the Alps, in France, and in Italy. He first practised medicine at Basel, where he was elected professor of rhetoric in 1566. He then resided for some time at Yverdun, and in 1570 was invited to be physician to the duke of Wurtemberg at Montbéliard,—a situation in which he spent the remainder of his life. He devoted his time chiefly to botany, on which he bestowed great labour. He likewise prosecuted other branches of natural history, and published an account of *Medicinal Waters throughout Europe*. His great work on plants was not completed at his death, which happened in 1613. A society at Yverdun published in 1619 the "Prodromus;" but it was not till 1650 and 1651 that the work itself appeared, in three vols. folio, entitled *Historia Plantarum nova et absolutissima, cum auctorum consensu et dissensu circa eas*. It was long considered a standard work, and, with all its defects, it entitles its author to a high place among the founders of botanical science.

BAUMÉ, Antoine, a French chemist, distinguished for his success in the practical application of the science, was born at Senlis in 1728. He was the son of an innkeeper, and had to contend with the disadvantages of a defective education, in spite of which he prosecuted his scientific researches with great success. He was apprenticed to the celebrated chemist Geoffroy, and in 1752 was admitted a member of the college of pharmacy; soon after he was appointed professor of chemistry at that establishment. He carried on a commercial establishment in Paris for the preparation, on an extensive scale, of drugs for medicine and the arts, such as the acetate of lead, the muriate of tin, mercurial salts, and antimonial preparations. At the same time he published a number of papers on chemical science, and on arts and manufactures. He established the first manufactory of sal-ammoniac in France, a substance which before that time had been obtained from Egypt. He was the first also who devised and set on foot a process for bleaching raw silk. Having acquired a competency by the success of these different undertakings, he retired from trade, and devoted his time to the application of chemistry to the arts. He improved the process for dyeing scarlet at the manufactory of the Gobelins, and announced a cheap process for purifying saltpetre. By the Revolution he lost his fortune, but this calamity, instead of disheartening him, stimulated him to resume his trade. He was chosen a correspondent of the Institute in 1796, and died in 1804 at the age of seventy-six. Many of his papers are published in the *Memoirs of the Academy of Sciences*. Of his separate publications, the following may be mentioned here: *Dissertation sur l'Ether*, in 12mo; *Plan d'un Cours de Chimie Expérimentale*, 1757, in 12mo; *Opuscules de Chimie*, 1798, in 8vo; *Élémens de Pharmacie Théorique et Pratique*, 2 vols. 8vo.; *Chimie Expérimentale et Raisonnée*, 3 vols. 8vo, 1773.

BAUMGARTEN, Alexander Gottlieb, a German philosopher, born at Berlin in 1714. He studied at Halle, and afterwards became professor of philosophy at Frankfort on the Oder, in which city he died in the year 1762. He was a disciple of Leibnitz and Wolff, and was particularly distinguished for his æsthetical speculations, having been the first to develop and establish the *Theory of the Beautiful* as an independent science. Baumgarten, of course, is not to be looked upon as the founder of æsthetics, but he did good service in severing it from the other philosophic disciplines, and in marking out a definite object for its researches. The very name (*Æsthetics*) which Baumgarten was the first to use for the science of the Beautiful, though now very generally adopted for the sake of convenience, indicates the imperfect and partial nature of his analysis, pointing as it does to an element so variable as *feeling* or *sensation* as the ultimate ground of judgment in questions pertaining to beauty. The principal works of Baumgarten are the following: *Disputationes de nonnullis ad poema pertinentibus; Æsthetica; Metaphysica; Ethica philosophica; Initia philosophiæ practicæ primæ*. For an account of his speculations on the theory of the Beautiful see Æsthetics, vol. i. p. 217.

BAUMGARTEN-CRUSIUS, Ludwig Friedrich Otto, a distinguished German theologian, was born in July 1788 at Merseburg. In 1805 he entered the university of Leipsic, and studied theology and philosophy. In 1812 he was appointed extraordinary professor of theology at Jena, where he remained to the end of his life, rising gradually to the head of the theological faculty. In the midst of his labours as professor and author, he was struck down by apoplexy, and died on the 31st May 1843. Baumgarten-Crusius lectured on almost all the theological disciplines, with the exception of church history; but his great strength lay in the treatment of the history of dogma. His comprehensive knowledge, accurate scholarship, and wide sympathies gave peculiar value to his lectures and treatises on the development of church doctrine. His published works were very numerous, the most important being—*Lehrbuch der Christlichen Sittenlehre*, 1826; *Grundzüge der biblischen Theologie*, 1828; *Lehrbuch der Dogmengeschichte*, 1832; *Compendium der Dogmengeschichte*, 1840. The last, perhaps his best work, was left unfinished, but was completed in 1846 by Hase from the author's notes. Commentaries on several of the books of the New Testament, gathered from his papers, were also published after his death.

BAUR, Ferdinand Christian, the distinguished leader of the Modern Tubingen School of Theology, was born in the neighbourhood of Cannstadt on the 21st June 1792. The son of a Würtemberg pastor, he entered, at the age of thirteen, the well-known seminary at Blaubeuren, to which his father had some years before been transferred as deacon. Thence he passed, in the year 1809, to the university at Tubingen. Solid and somewhat reserved in character, he was indefatigable in his studies, but did not come prominently to the front till near the close of his academic career. His intellectual development proceeded slowly from step to step. For a time he was attracted and considerably influenced by the study of Bengel, the great head of the preceding orthodox school, which had given

Tübingen its reputation in the 18th century. Both Bengel himself in his noble personality, and the historical character of his critical labours on the New Testament, remarkable for their time, had a charm for the youthful student of the 19th century. With historical interest Baur combined a special interest in the philosophy of religion, but as yet without betraying any opposition to the supernatural standpoint of the older theology. His earliest literary production —a review of Kaiser's Biblical Theology (Bengel's *Archiv für Theologie*, ii. 656) in 1817—shows nothing of this opposition. It required a change of circumstance, as well as a new impulse of intellectual excitement, to direct his thoughts into the bolder current, in which they were destined to run, and in their course so largely to affect the stream of contemporary thought.

In 1817 he was called as professor to Blaubeuren, which he had left as a pupil eight years before. It was his business here to direct the historical and philosophical studies of the youth, and his keen and comprehensive genius soon found a congenial subject of investigation in the relations of Christianity to preceding modes of thought. The result of his investigations appeared in his *Symbolik und Mythologie*, in 1824. This was his first elaborate work, the precursor of all his special studies in religious history and the development of religious thought. Animated by a thorough and enlightened spirit of learning, and valuable as a contribution to the knowledge of classical antiquity, it was yet dominated by a theological interest, and showed how truly this was the prevailing bias of the author's mind. It showed, moreover, how from this early period he combined, in almost equal force, the three great elements of culture—philological, philosophical, and theological—which his later works discovered in such maturity

This publication drew attention to Baur's marked abilities, and, on a vacancy occurring in the theological faculty at Tübingen, he was promoted after some hesitation to the chair of historical theology in that famous university, destined from his labours to acquire a yet more notable reputation. This took place in 1826; and for thirty-four years Baur's life was passed at Tübingen in an unceasing round of academic work,—while his name continued to gather from his successive writings an increasing lustre and influence. All accounts agree in testifying to his marvellous industry and unceasing toil of research, his conscientiousness and self-sacrifice as a teacher, and the unobtrusive enthusiasm and dignity with which he discharged all the duties entrusted to him, not only as a professor, but as for some time the head of the *Stift*, or college of residence for the Protestant divinity students. His theological opinions, trenchant and alarming as they must have sometimes appeared, never made any separation betwixt him and his colleagues in the theological faculty. All acknowledged his power and earnestness; and the multitudes who thronged his lecture-rooms carried the impulses of his thought throughout Germany and Switzerland. His manner was somewhat reserved and silent; all his enthusiasm was put into his work, and was felt more as an underglow animating his lectures and writings than as a demonstrative power creating a temporary noise. He lived for theological science: nothing else seems to have occupied him or drawn him aside. When we add to this the fact that any faith in supernatural religion, with which he began his labours as a professor, ere long disappeared, and that the great aim of all his studies and researches was to find the natural factors or principles out of which Christianity arose in the world, there is presented to us a strange picture of theological enthusiasm. It may seem an inconsistent and unhappy picture. Yet there is something heroic if also pathetic in such intense application to the study of Christian phenomena, and such thorough and earnest aims to reach the truth regarding them, without the faith which witnesses to the reality of a personal divine life, behind the phenomena and revealed in them.

Baur at first, like almost all his contemporaries, owned the influence of Schleiermacher. The *Glaubenslehre* of the latter, which appeared in 1821, is said to have affected him deeply, and moulded his thought for some time. But there was too little affinity betwixt the men,—the one mystic and spiritual, the other intellectual and objective, —to permit this influence to be permanent. From Schleiermacher Baur passed to Hegel, whose commanding genius laid its spell upon him as upon others. The Hegelian philosophy became the permanent and pervasive element of his intellectual life. Its great doctrine of opposites, or of extremes finally terminating in a conciliation, is found more or less to underlie all his thought, and to furnish the key to his most daring speculations on the origin and growth of Christianity.

It was not, however, till nearly ten years after his settlement at Tübingen that his theological views underwent a decided change, and that the special tendency known as that of the Modern Tübingen School was fully developed. The earlier period of Baur's academic life was not unfruitful, but did not mark him off in any striking manner. Even his treatise on the *Christ-party in the Corinthian Church and the Antagonism betwixt the Pauline and Petrine Christianity*, which appeared in 1831, and which may be said to contain the germs of his future system, was published peaceably (in the *Tübingen Zeitschrift*) along with the effusions of Steudel, one of his co-professors most devoted to supernaturalism. His answer to Möhler's famous *Symbolik* (1833) attracted a widespread reputation, and fixed attention upon him as one of the ablest defenders of German Protestantism. Masterly and ingenious as Möhler's book was, it was felt that Baur had not only fairly met but overthrown its chief position. But with all his reputation as a powerful writer and controversialist, he had hardly as yet made his mark as a new thinker.

The second and distinctive period of his intellectual development is dated from the year 1835, when Strauss's *Leben Jesu* appeared and spread commotion in the theological mind of Germany. In the same year Baur published his great work on Gnosticism, in which he had obviously quite passed beyond the influence of Schleiermacher. A brief work on the *So-called Pastoral Epistles* in the same year showed him at work in an independent critical direction, and ready to take a new start in theological inquiry. This start, or at least the lengths to which it carried him, have been by many attributed to the effect of Strauss's work. But he has himself plainly denied this, and claimed an independent origin for his own speculations. "I had begun," he says (*Kirchengeschichte des 19 Jahrhunderts*, 395), "my critical inquiries long before Strauss, and set out from an entirely different point of view. My study of the two epistles to the Corinthians led me first to seize clearly the relation of the apostle Paul to the other apostles. I was convinced that in the letters of the apostle themselves there was enough from which to infer that this relation was something very different from that usually supposed,—that, in short, instead of being a relation of harmony it was one of sharp opposition, so much so that on the part of the Jewish Christians the authority of the apostle was held everywhere in dispute. A closer investigation of the Pseudo-Clementine homilies, to whose significance in reference to the earliest period of Christian history Neander first drew attention, led me to a clearer understanding of this opposition; and it always became more evident to me that the contrast of the two parties in the Apostolic and sub-Apostolic age must be traced

not merely in the formation of the Petrine tradition but as having exercised an important influence upon the composition of the Acts of the Apostles."

This supposed conflict betwixt Petrinism and Paulinism, or, in other words, betwixt Jewish and Gentile Christianity, lies at the foundation of all Baur's critical labours. His speciality as a New Testament scholar and critic was the firmness with which he laid hold of what he believed to be the only genuine foundation of historical Christianity in St Paul, and his four great epistles to the Corinthians, to the Galatians, and to the Romans. These epistles were to him alone unchallengeable as the authentic writings of the great apostle of the Gentiles, and the antagonism of which he made so much appeared to him everywhere to pervade them. The epistles to the Ephesians, to the Colossians, and to the Philippians, and the short letter to Philemon, were at the best doubtfully genuine. They seemed to him to bear traces of a later Gnosticism in many of their expressions, while he altogether rejected the apostolical character of the Pastoral Epistles. These letters, as well as the Acts of the Apostles, were to him writings not of the 1st but of the 2d century, proceeding not from the Pauline School, but from the Catholic and Conciliatory School, which towards the middle and end of the 2d century sought to adjust and harmonize the earlier conflicting elements of Petrinism and Paulinism. This impress of conciliation and compromise appeared to him to be specially stamped upon the Acts of the Apostles, and to be the true explanation of the relations there depicted betwixt St Peter and St Paul.

Such were the views advocated by Baur in a succession of writings on the Pastoral Epistles (1835) and the Epistle to the Romans (1836); but especially in his great work on the Apostle Paul (1845), which may be said to sum up the result of his critical labours on the Pauline writings.

Then in a further series of critical investigations he turned his attention to the Gospels. He dealt with them as a whole, "their relation to one another, their origin, and character," in a treatise which appeared in 1847, and in 1851 he devoted a special volume to the gospel of St Mark. The result of his investigations in this direction was to satisfy him that all the Gospels owe their origin more or less to the same tendencies or traces of party design, which he everywhere discovers in the first Christian age. Our present Gospels are not, in his view, the most ancient documents of the kind possessed by the church. Before them there was a primary cycle of evangelical tradition, known by various names—as the gospel of the Hebrews, of St Peter, of the Ebionites, of the Egyptians, &c. In the existing canon the Gospel of St Matthew resembles those earlier narratives most closely. It reproduces most completely the character of the primitive Jewish Christianity, yet not without important later modifications. The Gospel of St Luke is, of course, of Pauline origin, yet also retouched with a view to the conciliatory tendencies of the Church of the 2d century and the influence of the Petrine tradition. That of St Mark is of later date than either, and bears the most evident traces of adaptation. Of all the gospels it is the most suspected by the Tübingen School. The Fourth Gospel, on the other hand, is a definite work, but of the 2d, not of the 1st century. An examination of its contents, its mode of composition, and its general plan clearly reveals its dogmatic and idealistic character. The historical data are merely a background to the speculative ideas which it unfolds. The prologue by itself is sufficient proof of its logical method and purpose, while the contrasts which everywhere pervade it betwixt light and darkness, life and death, the Spirit and the flesh, Christ and the children of the devil, and the dramatic force and propriety with which these contrasts are handled throughout, point to the same conclusion. Further, the differences betwixt the Apocalypse and the Fourth Gospel are held to show conclusively that they could not have proceeded from the same author.

In addition to these critical labours Baur distinguished himself by a series of elaborate historical monographs on special doctrines of Christianity, for example his *History of the Doctrine of the Atonement* in 1838, and his *History of the Doctrine of the Trinity and Incarnation*, in 3 volumes, in 1841–3. His unceasing activity further produced a *Handbook of the History of Dogma* in 1847, an interesting tract on the *Chief Epochs of Ecclesiastical History* (1852), an admirable digest of his general views on the origin and growth of the early church under the title of *The Christian Church of the First Three Centuries* (1853). A further volume of general Church History from the 4th to the 6th century, appeared from his pen just before his death (1859), and subsequently three volumes containing the History of the Church of the Middle Ages (1861), the History of the Church of more recent times (1863), and the Christian History of the 19th century (1863). Finally, in 1865, appeared *Lectures on the History of Christian Dogma*.

His death took place on the 2d December 1860. He lies buried in the cemetery at Tübingen, not far from the poet Uhland, with the simple inscription on his tomb, "F. C. Baur, Theolog."

Such an amount and variety of authorship sufficiently show Baur's indefatigable industry and enthusiasm as a theologian; and when it is remembered that all his works are of a strictly scientific character indicating everywhere original research, and a penetrating and systematic intelligence which never slumbers, however it may be mistaken, it is evident that there are few names in the recent history of theology that claim more significance than that of Ferdinand Christian Baur. Of the value of his labours and the extent to which his theological views may be said to have verified themselves in the modern mind which has continued profoundly agitated by the problems which he started, this is not the place to speak. It need only be said that, while many of his opinions are strongly contested, and some of the most enlightened recent investigations prove that he has greatly exaggerated the antagonisms of the early church, and post-dated most of the writings of the New Testament, it is at the same time admitted by all advanced scholars that he has, even in his exaggerations, contributed to a clearer view of the great principles at work in the 1st and 2d centuries and the lines of spiritual movement along which the Christian church moved to its historical formation and development. No student since Baur can fail to recognize the distinctive influences of Jewish and Gentile Christianity, and the extent to which this distinction, and in some cases antagonism, are impressed upon the New Testament writings. To him also and his school must be attributed the modern idea that the surest historical foot-hold of Christianity is in the four great Pauline epistles. These, more than any other New Testament writings, lie in the clear dawn of the sun-rise which enlightened the world. The Gospels remain, not indeed in a mist of unauthentic story, but in comparative shadow. They come only gradually into the light after a long dim undergrowth in the rich soil of Primitive Christianity. There is much to be said against Baur's views of their later origin in the 2d century. The more this century is studied the less does it seem capable of originating such marvellously fresh products of spiritual intelligence. But it is not the less certain that the Synoptic Gospels took their present form only by degrees, and that while they have their root in the Apostolic Age and the Apostolic mind, they are also fashioned by later influences, and adapted to special wants in the Early

Church. They are the deposits, in short, of Christian tradition, handed down first of all, and probably for a considerable period, in an oral form, before being committed to writing in such a form as we now have them. This, which is now an accepted conclusion with every historical school of theologians in England no less than in Germany, conservative no less than radical, is largely the result of the Tubingen investigations. It may have been understood before, but its historical significance was not appreciated. In short, if we distinguish Baur's method from his special opinions it is hardly possible to overrate his influence as a theologian. His professed method was to seek for the solution of great spiritual as of great intellectual phenomena in a closer and more minute study of all the documents and data purporting to record or explain these phenomena, and to run out such lines of fact as he found to their true consequences. His great genius and learning enabled him to read the meaning of certain features of Primitive Christianity hitherto imperfectly discerned, and to point future inquirers along the true road of discovery. Unhappily, his own opinions were influenced not merely by his study of facts, but by a great speculative system which dominated his intelligence, and prevented him from seeing what still seems to most minds not less informed than his own the only credible explanation of the vast spiritual movement whose forces and developments occupied his lifelong study. (J. T.)

BAUTAIN, LOUIS EUGÈNE MARIE, a French philosopher and theologian, was born at Paris in February 1796, and died in October 1867. At the École Normale he came under the influence of Cousin, whose views on most philosophic points he at first accepted. In 1816 he adopted the profession of higher teaching, and was soon after called to the chair of philosophy in the University of Strasburg. He continued in this position for many years, delivering a parallel course of lectures as professor of the literary faculty in the same city. The strong reaction against merely speculative philosophy, which carried away such men as De Maistre and De Lamennais, was not without influence on Bautain. In 1828 he took orders, and resigned his chair at the university. For several years he remained at Strasburg, lecturing at the Faculty and at the College of Juilly; but in 1849 he set out for Paris as vicar of the diocese. At Paris he obtained considerable reputation as an orator, and in 1853 was made professor of moral theology at the theological faculty. This post he held till his death. Bautain is rather a scholastic than a modern philosopher. His view of the relation between reason and faith is essentially the same as that of Anselm and his great successors. Revelation is supposed to give materials which could not otherwise have been attained by the human mind, and philosophy supplies the scientific exposition or evolution of these facts. Theology and philosophy thus form one comprehensive science; yet the system is far removed from Rationalism. Bautain in fact, like Pascal, Newman, and others, depreciates reason in order to exalt faith. He points out, following chiefly the Kantian criticism, that reason is limited in application, and can never yield knowledge of things as they are in themselves. But in addition to reason, we have, according to him, another faculty which may be called Intelligence, and through which we are put in connection with the world of spiritual and invisible truth. This intelligence does not of itself yield a body of truth; it merely contains the germs of the higher ideas, and these seeds are made productive by being brought into contact with revealed facts. This fundamental conception Bautain works out in detail in the departments of psychology and morals. His works, to which we can only refer, are well deserving of attention. The most important of them are—*Philosophie du Christianisme*, 1833; *Psychologie Expérimentale*, 1839 (new edition entitled *Esprit Humain et ses Facultés*, 1859); *Philosophie Morale*, 1842; *Religion et Liberté*, 1848; *La Morale de l'Évangile comparée aux divers systèmes de Morale*, 1855.

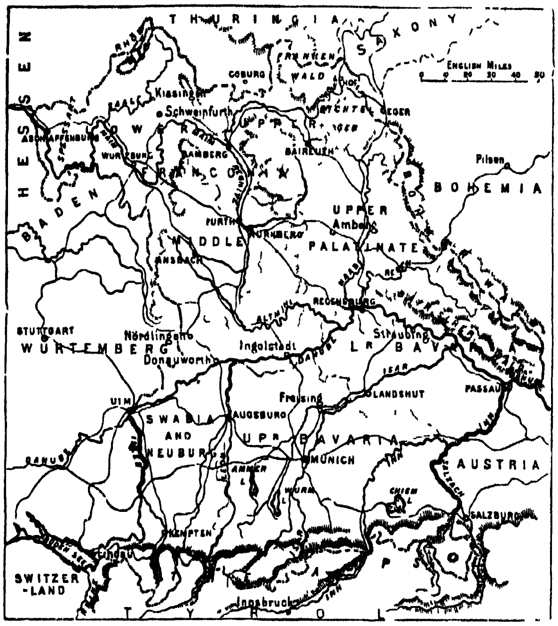
BAUTZEN (in Wendish *Budissin*, which is equivalent to "town"), the capital of Saxon Upper Lausatia, occupies an eminence on the right bank of the Spree, 680 feet above the level of the sea, and 32 E.N.E. from Dresden. Lat. 51° 11′ 10″ N., long. 14° 25′ 50″ E. The town is well built and surrounded by walls, and has extensive suburbs partly lying on the left bank of the river. It has a cathedral which is used by both Protestants and Roman Catholics, and five other churches, a handsome town-house, an orphan-asylum, several hospitals, a mechanics' institute, a famous gymnasium, a normal and several other schools, and two public libraries. Its general trade and manufactures are considerable, including linen, cotton, and woollen goods, tobacco, leather, paper, saltpetre, gunpowder, &c. Population in 1871, 13,165. Bautzen was already in existence when Henry the Fowler conquered Lausatia in 928. It became a town and fortress under Otto I., his successor, and speedily attained considerable wealth and importance, for a good share of which it was indebted to the pilgrimages which were made to the "Arm of St Peter," preserved in one of the churches. It suffered greatly during the Hussite war, and still more during the Thirty Years' War, in the course of which it was besieged and captured by the Electoral Prince, John George (1620), fell into the hands of Wallenstein (1633), and was burned and taken by the Electoral Prince of Saxony. At the Peace of Prague in 1635 it passed with Lausatia to Saxony as a war indemnity. The battle of Bautzen was fought here on the 21st and 22nd of May 1813, between the French under Napoleon and the allied forces of Russia and Prussia, in which, after severe losses on both sides, the latter were defeated.

BAVARIA

BAVARIA (in German, *Bayern*), a kingdom of Southern Germany, forming part of the German Empire, consists of two distinct portions, Bavaria proper and the Palatinate of the Rhine, which are separated by the grand duchies of Baden and Hesse. Bavaria proper contains an area of about 26,895 miles, and the Palatinate rather less than 2282, making the whole extent of the kingdom about 29,177 square miles.

Physical features. The frontier of Bavaria proper on the north-east, towards Bohemia, consists of a long range of mountains known as the Böhmerwald; while the north is occupied by the Fichtelgebirge and the Frankenwald, which separate Bavaria from Reuss, Meiningen, and Hesse-Darmstadt. The ranges last named seldom exceed the height of 3000 or 4000 feet; but the ridges in the south, towards the Tyrol, form part of the system of the Alps, and frequently attain an elevation of 9000 or 10,000 feet. On the west it is bounded by Würtemberg, Baden, and Hesse-Darmstadt. The whole of the country belongs to the basins of the Danube and the Main; by far the greater portion being drained by the former river, which, entering from Swabia as a navigable stream, traverses the entire breadth of the kingdom, with a winding course of 200 miles, and receives in its passage the Iller, the Lech, the Isar, and the Inn from the south, and the Naab, the Altmühl, and the Wörnitz from the north. The Inn is navigable before it enters the

Bavarian territory, and afterwards receives the Salza, a large river flowing from Upper Austria. The Isar does not become navigable till it has passed Munich; and the Lech is a stream of a similar size. The Main traverses the northern regions, or Upper and Lower Franconia, with a very winding course, and greatly facilitates the trade of the provinces. The district watered by the southern tributaries of the Danube consists for the most part of an extensive plateau, with a mean elevation of 2390 feet. In the mountainous parts of the country there are numerous lakes, and in the lower portions considerable stretches of marshy ground. The climate of Bavaria differs greatly



Sketch Map of Bavaria Proper.

according to the character of the region, being cold in the vicinity of the Tyrol but warm in the plains adjoining the Danube and the Main. On the whole, the temperature is in the winter months considerably colder than that of England, and a good deal hotter during summer and autumn.

Forest. The extent of forest is more than twice that of the land under wood in Great Britain. It forms more than a fourth of the total area of Bavaria, while in Britain the proportion is less than a twenty-sixth. This is owing to various causes—the extent of hilly and mountainous country, the thinness of the population, and the necessity of keeping a given extent of ground under wood for the supply of fuel. Nearly a third of the forests are public property, and furnish a considerable addition to the revenue. They are principally situated in the provinces of Upper Bavaria, Lower Bavaria, and the Upper Palatinate.

Agriculture. The level country, including both Lower Bavaria (extending northwards to the Danube), and the western and middle parts of Franconia, is very productive in rye, oats, wheat, barley, and millet, and also in hemp, flax, hops, madder, and (in warm situations) in vines. The last are grown chiefly in the vicinity of the Lake of Constance and on the banks of the Main, in the lower part of its course, while the most extensive hop-growing district is central Franconia. Potatoes are cultivated in all the provinces, but especially in the Palatinate and in the Spessart district, which lies in the north-west within a curve of the Main. The southern division of Swabia and Upper Bavaria, where pasture-land predominates, form a cattle-breeding district, and the dairy produce is extensive, no less than 11,000 tons of cheese and 2386 tons of butter being sold in the course of a year. The former finds a market all over Germany, and is also exported to Austria, France, and other countries, while Northern Germany is the chief consumer of the latter. The greater proportion of the land throughout the kingdom is in the hands of peasant proprietors, the extent of the separate holdings differing very much in different districts. The largest peasant property may be about 170 English acres, and the smallest, except in the Palatinate, about 50.

Live Stock. According to the returns for 1863 the number of cattle in the kingdom was 3,185,688; sheep, 2,058,638; swine, 926,522; and goats, 150,855. Oxen are largely employed in agricultural operations instead of horses. The cattle, as a general rule, are kept in sheds, and not pastured in the fields.

Minerals. Of mineral deposits Bavaria possesses a great variety. The quantity of iron ore is very large both in the south and north, the number of mines being between 200 and 300. Coal-mines are likewise numerous, especially in the districts of Amberg, Kissingen, Steben, Munich, and the Rhine Palatinate. The produce in 1867 was nearly 351,000 tons. Of quicksilver there are several mines, chiefly in the Palatinate of the Rhine; and small quantities of copper, manganese, and cobalt are obtained. There are numerous quarries of excellent marble, alabaster, gypsum, and building stone; and the porcelain-clay is among the finest in Europe. To these may be added graphite, emerite, steatite, barytes, felspar, and ochre, in considerable quantities; excellent lithographic stone is obtained at Solnhofen; and gold and silver are still worked to an insignificant extent. Salt is annually prepared on a large scale, being obtained partly from brine springs and partly from mines. The principal localities are Halle, Berchtesgaden, Traunstein, and Rosenheim. The gross production in 1866 was 41,119 tons, and the value at the works amounted to £62,869. In the following year the Government monopoly, which had existed so long, was abolished, and free trade was established in salt between the members of the customs-union, a change which has led to a considerable import of salt from Prussia.

Manufactures. A great stimulus was given to manufacturing industry in Bavaria by the law of 1868, which abolished the last remains of the old restrictions of the guilds, and gave the whole country the liberty which had been enjoyed by the Rhine Palatinate alone. The chief manufacturing centres are Nuremberg and Munich for hardware, and Augsburg for cloth goods; but various other towns are rising into importance. In Franconia are numerous paper-mills, and saw-mills are naturally common in the forest districts. A considerable quantity of glass is manufactured, especially in the Bohmerwald, and wooden wares are largely produced at Ammergau and Berchtesgaden. The preparation of the favourite national drink forms an important industry,—the breweries throughout the kingdom numbering upwards of 5000. Among the most remarkable are the breweries of Erlangen. Other articles of manufacture are leather, tobacco, and earthenware.

Trade. The exports from Bavaria consist chiefly of salt, timber, cattle, pigs, corn, and madder; and the imports comprise sugar, tobacco, raw cotton and cotton-goods, silks and linen, iron, and iron-wares. As most of the imports are introduced indirectly through other Zollverein states, no custom-house register is kept of the total amount.

Communication. The highroads in Bavaria extend in all over 9000 miles. In 1869 there were rather more than 1600 miles of railway in operation, and nearly 300 were in course of construction. The greater proportion is in the hands of the Government, and the remainder belongs to the Eastern Company and the United Railway Companies of the Rhine Palatinate. The principal canal in the kingdom is the Ludwigs-canal, which connects the Rhine with the Danube, extending from Bamberg on the Regnitz to Dietfurt on

the Altmühl. There is an extensive network of telegraphs, all of which belong to, and are worked by, the Government post-office.

National character. The Bavarians proper form a distinct section of the German race, speaking a well-defined dialect of the High German; but a large portion of the population of the country is of Swabian origin. The national character resembles that of the Austrians, being generally marked by fidelity and loyalty. In matters of religion they are credulous and even superstitious; and the will of their superiors is received by the lower orders with great deference both in political and ecclesiastical affairs. Independence of thought and action have, however, been gradually increasing; and now that the country has become part of the German empire, a rapid transfusion of intellectual and political life is apparently taking place.

Government. The present form of government is founded partly on long-established usage and partly on a constitutional act, passed in May 1818, and modified by subsequent acts, of which the most important was passed in 1848–9. The monarchy is hereditary, with a legislative body of two houses. The title of the sovereign is simply king of Bavaria; that of his presumptive heir is crown-prince of Bavaria. The executive power is vested altogether in the king, whose person is declared inviolable, the responsibility rests with the ministers, whose functions are nearly the same as those of ministers in England; and there are offices for foreign affairs, for the home department, for religion and education, for the treasury, the army, and the administration of justice. These are all situated in Munich, the capital. The upper house of the Bavarian parliament, known as the Chamber of the *Reichsräthe*, comprises the princes of the blood-royal, the two archbishops, the barons or heads of certain noble families, a Roman Catholic bishop and Protestant clergyman appointed by the Crown, and any other members whom the king may nominate either as hereditary peers or as counsellors for life; but these last must not exceed a third of the hereditary members. The lower house, or Chamber of Representatives (*Wahlkammer*), consists of about 150 deputies, who formerly were chosen in definite proportions from the different classes of the community, an eighth part from the nobility, another eighth from the clergy, a fourth part from the burghers, and the remaining half from the landed proprietors; but since 1848 they may be selected without any such restrictions. A general election takes place once in six years, one deputy being allowed for every 7000 families in the kingdom. The election, however, is indirect,—electoral proxies, or *Wahlmänner*, to whom the real election is entrusted, being chosen by the general body of electors at the rate of one proxy to every 500 men. The king generally convenes the parliament once a year, and by the constitution it is obligatory on him to do so at least once in three years.

Revenue. The following is a statement of the budget for the year 1874–5, in marks (equal to 1s. sterling):—

RECEIPTS.

Direct Taxes.	Marks.	
Land tax	11,438,323	
Tax on buildings	1,995,086	
Tax on licences	2,820,000	
Tax on capital	1,628,571	
Tax on income	857,143	
		18,739,123
Indirect Taxes.		
Registration	10,889,006

Total	136,846,594
Expenses of administration	75,205,274
	212,051,868 Marks,
	or £10,602,593

Army. The Bavarian army forms, since the 23d November 1870, a separate portion of the army of the German empire, with a distinct administration; but its organization is subject to the general imperial rules, and in time of war it is placed under the command of the emperor. It comprises two *corps d'armée*, each divided into two divisions. In time of peace its infantry consists of 26,590 men, distributed in sixteen regiments; besides which there are ten battalions of *chasseurs*, 5500 strong, and thirty-two battalions of *landwehr;* the cavalry numbers 7200 men divided into ten regiments, and the artillery amounts to 5528 men in six regiments; there are also two battalions of pioneers and as many of the military train. In time of war the total force is raised to 149,892, or rather more than trebled.

Religion. The districts of Lower Bavaria, Upper Bavaria, and the Upper Palatinate are almost wholly Catholic, while in the Rhine Palatinate, Upper Franconia, and especially Middle Franconia, the preponderance is on the side of the Protestants. The exercise of religious worship in Bavaria is altogether free. The Protestants have the same civil rights as the Catholics, and the sovereign may be either Catholic or Protestant. Of the Roman Catholic Church the heads are the two archbishops of Munich-Freising and Bamberg, and the six bishops of Eichstädt, Spire, Würzburg, Augsburg, Regensburg, and Passau, of whom the first three are suffragans of Bamberg. The "Old Catholic" party has recently taken considerable hold of the country, and has organized congregations in all the more important towns. Among the Protestants the highest authority is the general consistory of Munich. The proportion of the different religions in 1871 was as follows:—Roman Catholics, 3,464,364; Protestants, 1,342,592; Jews, 50,662; lesser Christian sects, 5453; other religions, 379.

Bavaria was formerly as backward in regard to educa-

tion as Austria, or any part of the south of Germany; but latterly considerable efforts have been made to lessen the prevailing ignorance. At Munich there are scientific and literary academies, as well as a university, a lyceum, a gymnasium, and other public schools. The university has a very numerous attendance of students, ranking third in the new German empire; and there are two provincial universities on a small scale, one (Catholic) at Würzburg, the other (Protestant) at Erlangen in Franconia. In the kingdom at large there are ten lyceums, twenty-eight gymnasia, about sixty progymnasia, besides ten normal, twenty-six trade, three polytechnic, and upwards of 7000 common schools. These certainly form a great contrast to the indifference and neglect of former times; and the Government continues to evince much solicitude for the diffusion of instruction. Technical schools here, as in other parts of Germany, have been established for the purpose of affording to mechanics more suitable education than they could otherwise obtain, including mathematics, mechanics, drawing, chemistry, architecture, &c. These schools are supported by the commune, aided when necessary by the province, and commissioners are annually sent by Government to examine and report upon them to the minister of trade. The course extends over three years, from the age of twelve to fifteen, after which pupils may enter one of three polytechnic schools, where a still higher course of instruction is imparted, also extending over three years; but engineers have a special fourth year's course. A building school was established at Munich in 1823, and is chiefly intended for carpenters and masons, who are there instructed in architecture, drawing, geometry, stone-cutting, modelling ornaments, &c.

Provinces. The duchy of Bavaria during the Middle Ages consisted of the southern half of the present kingdom, and lay almost all to the south of the Danube, extending about 100 miles from that river to the Tyrol, and somewhat more from Swabia on the west to Austria on the east. The addition in 1623 of the Upper Palatinate, a province of full 3000 square miles, to the north of the Danube, gave the elector a territory of about 15,000 square miles, with a population of less than 1,000,000, which in a century and a half had increased to about 1,500,000. In 1778 the succession of the Rhenish branch of the reigning family added the Palatinate of the Rhine, and in 1806 a large augmentation was effected by Napoleon, who presented the king with the districts of the Lower Main and the Rezat, and with part of those of the Upper Main and the Upper Danube; not to mention Tyrol, which was afterwards restored to Austria. Some slight changes have taken place in the extent of the kingdom since then; but its general character has not been affected. The most important cession of recent years was that of part of Franconia in 1866 to Prussia, amounting to 291 square miles, with a population of 32,976 inhabitants.

Population. The following table gives the present and former division of the kingdom and its population in 1818, 1846, and 1871 respectively:—

Old Circle	New Circles.	Area in Eng. Miles	Population.		
			1818.	1846.	1871.
Isar	Upper Bavaria	6556	585,467	705,544	841,707
Lower Danube	Lower Bavaria	4141	450,895	543,709	603,789
Regen	Upper Palatinate	3717	403,481	467,606	497,861
Upper Main	Upper Franconia	2692	394,954	501,163	541,063
Rezat	Middle ,,	2906	437,838	527,866	583,666
Lower Main	Lower ,,	3230	501,212	592,080	586,132
Upper Danube	Swabia	3651	487,951	558,436	582,773
Rhine	Rhine Palatinate	2282	446,168	608,470	615,035

The total population in 1871, including the troops then absent in France, amounted to 4,863,450. The density of population varies considerably in the different districts from about 273 inhabitants to the square mile in the Palatinate to 128 in Upper Bavaria. As represented by the increase of each successive census the growth of the population is rather slow, but a large amount of emigration to America and elsewhere has to be taken into account. A very considerable number of the people are urban, as may be seen from the following list of principal towns (arranged in the order of the circles) with their populations:—

Upper Bavaria	Munich (capital)	169,693
	Ingolstadt	13,157
Lower Bavaria	Landshut	14,140
	Passau	13,379
	Straubing	11,150
Upper Palatinate	Ratisbon (or Regensburg)	29,185
	Amberg	11,688
Upper Franconia	Bamberg	25,738
	Bayreuth	17,841
	Hof	16,010
Middle Franconia	Nuremberg	83,214
	Furth	24,577
	Ansbach	12,636
	Erlangen	12,510
Lower Franconia	Wurzburg	40,005
	Schweinfurt,	10,325
	Aschaffenburg	9,212
Swabia	Augsburg	51,220
	Kempten	11,223
Palatinate of Rhine	Kaiserslautern	17,896
	Spire	13,223
	Neustadt	9,320

History. The name in German, *Bayern*, or *Baiern*, is derived like Latin *Boiaria*, from Boii, the name of a Celtic people by whom the country, which then formed part of Rhætia, Vindelicia, and Noricum, was inhabited in the time of Augustus. After the fall of the Roman power the natives were governed by chieftains of their own till the era of Charlemagne, who subjugated this as well as most other parts of Germany. After his death Bavaria was governed by one of his grandsons, whose successors bore the title of Margrave, or Lord of the Marches. In the year 920 the ruling margrave was raised to the rank of duke, which continued the title of his successors for no less than seven centuries. During this period Bavaria was connected with Germany nationally by language and politically as a frontier province, but in civilization was almost as backward as Austria, and was greatly behind Saxony, Franconia, and the banks of the Rhine. At last, in 1620, the reigning duke, having rendered great service to Austria against an insurrection in Bohemia, received an important accession of territory at the expense of the Elector Palatine, and was appointed one of the nine electors of the empire. His successors continued faithful members of the Germanic body and allies of Austria until 1771, when the elector Max Emanuel began to assist Louis XIV. of France by threatening and attacking Austria, so as to prevent her from co-operating efficiently with England and Holland. This induced the duke of Marlborough, in the spring of 1704, to march his army above 300 miles from the banks of the Meuse to invade Bavaria, the fate of which was decided by the battle of Blenheim on the 13th August 1704. For ten years from this date the elector and his remaining forces served in the French armies, and his country was governed by imperial commission until the peace of Utrecht, or more properly that of Baden, in 1714, reinstated him in his dominions.

His son Charles Albert, who succeeded him in 1726, untaught by these disasters, renewed his connection with France; and, in 1740, on the death of the emperor of Germany, came forward as a candidate for the imperial crown. He obtained the nomination of a majority of the electors, and overran a considerable part of the Austrian territory; but his triumph was of short duration, for the armies of Maria Theresa not only repulsed the Bavarians,

but obtained in 1744 possession of the electorate. The elector died soon after, and his son Maximilian Joseph recovered his dominions only by renouncing the pretensions of his father.

Bavaria now remained tranquil above thirty years, until 1777, when, by the death of Maximilian, the younger line of the house of Wittelsbach, the line which had long ruled in Bavaria, became extinct. The next heir was Charles Theodore the Elector Palatine, the representative of the elder line of Wittelsbach; but Austria unexpectedly laid claim to the succession, and took military possession of part of the country. This called into the field, on the side of Bavaria, Frederic II. of Prussia, then advanced in years; but, before any blood had been shed, Austria desisted from her pretensions, on obtaining from Bavaria the frontier district which bears the name of Innviertel, or the Quarter of the Inn.

Bavaria again remained at peace until the great contest between Germany and France began in 1793, when she was obliged to furnish her contingent as a member of the empire. During three years her territory was untouched; but in the summer of 1796, a powerful French army under Moreau occupied her capital, forced her to sign a separate treaty with France, and to withdraw her contingent from the imperial army. The next war between France and Austria, begun in 1799, ending disastrously for the latter, the influence of France in the empire was greatly strengthened, so that, when the Austrians once more took up arms, in 1805, Bavaria was the firm ally of France, and for the first time found advantage in the connection,—its elector, Maximilian Joseph, receiving from Napoleon the title of king and several additions of territory.

Bavaria continued to support the French interest with her best energies till 1813, when, on condition of her late acquisitions being secured to her, she was led to join the Allies, and her forces contributed largely to the ultimate defeat of Bonaparte. In 1818 Maximilian presented his country with a constitution, of rather a mixed character, in which an attempt was made at once to satisfy the growing desire for political liberty and to maintain the kingly power. At the same time several beneficial measures, such as the abolition of serfdom, were effected in the earlier sessions of the new parliament. In 1825 Maximilian was succeeded by his son Louis, who distinguished himself as a promoter of the fine arts, but proved himself destitute of political capacity, and in consciousness of his disagreement with the spirit of his times, abdicated in March 1848 in favour of his son Maximilian II. It was not long before the difficulties of the new king were distinctly brought to view by the insurrection of the democratic party in Westphalia. By the assistance of Prussia the rising was quelled, and punishment was so ruthlessly inflicted by the tribunals that the trials became known as the bloody assizes. An anti-liberal reaction set in, and many of the political gains of former years were consequently lost. In 1864 King Maximilian II. was succeeded by his son (Louis II.); and at this time the great question on the future hegemony of Germany was being agitated throughout the country. In the war of 1866 the Bavarian Government and people threw in their lot with Austria, shared in the contest, and were involved in the defeat and loss. On the withdrawal of Austria from the German confederation a change of policy was introduced, and the Government veered round to the interests of Prussia, a course which was confirmed by the Franco-German War of 1870, when Bavaria took an active part with Prussia against the common enemy. Much ferment, however, remained in the country, and religious elements were introduced into the political discussions. The clerical, or, as it styles itself, the patriot party, is opposed to Prussian influence, and contends for "particularism," wishing to maintain a greater degree of independence for Bavaria than seems to be compatible with imperial unity. For a number of years the Government has been in the hands of the Liberal party. Thus a series of the most important measures have been passed with a liberal tendency, and the country is being gradually assimilated to the more advanced states of Northern Germany. The focus of the Liberal party is the Palatinate of the Rhine, while the "patriots" are mainly recruited from the districts of Old Bavaria. The decisive triumph of the former was marked by the treaty of November 23, 1870, between Bavaria and the Confederation of Northern Germany, which was followed by the recognition of the king of Prussia as the head of a new German empire. At the same time a greater degree of independence was granted to Bavaria than to the other members of the Confederation; it was freed from the domiciliary surveillance of the empire, and allowed to retain the administration of its own postal and telegraph systems, while its army has a separate organization, and during peace is under the command of the Bavarian king.

BAXAR, or BUXAR, a town of Hindustán, in the province of Behar, district of Sháhábád, on the south bank of the Ganges, in 25° 32′ N. lat., 84° 3′ E. long. The fort, though of small size, was important from its commanding the Ganges, but is now dismantled. The place is distinguished by a celebrated victory gained on the 23d October 1764 by the British forces under Major (afterwards Sir Hector) Munro, over the united armies of Sujá-ud-Daulah and Kasim Ali Khán. The action raged from 9 o'clock till noon, when the enemy gave way. Pursuit was, however, frustrated by Sujá-ud-Daulah sacrificing a part of his army to the safety of the remainder. A bridge of boats had been constructed over a stream about 2 miles distant from the field of battle, and this the enemy destroyed before their rear had passed over. Through this act 2000 troops were drowned, or otherwise lost; but destructive as was this proceeding, it was, says Major Munro, "the best piece of generalship Sujá-ud-Daulah showed that day, because if I had crossed the rivulet with the army, I should either have taken or drowned his whole army in the Karamnásá, and come up with his treasure and jewels, and Kasim Ali Khán's jewels, which I was informed amounted to between two and three millions." Population in 1872, 13,446.

BAXTER, ANDREW, an able metaphysician, the son of a merchant in Old Aberdeen, was born in 1686 or 1687, and educated at King's College there. After leaving the university he acted for some years as tutor to various young gentlemen, among others to Lord Gray, Lord Blantyre, and Mr Hay of Drummelzier. In 1733 he published, in quarto, but without date, *An Inquiry into the Nature of the Human Soul*, wherein its immateriality is deduced from the principles of reason and philosophy. In 1741 he went abroad with Mr Hay, and resided several years at Utrecht, from which place he made excursions into Flanders, France, and Germany. He returned to Scotland in 1747, and resided at Whittingham, in Haddingtonshire, till his death, which occurred on April 23, 1750. His principal work, besides the *Inquiry*, was a short dialogue entitled *Matho, sive Cosmotheoria puerilis, Dialogus in quo prima elementa de mundi ordine et ornatu proponuntur*, &c. This was afterwards greatly enlarged, and published in English in two volumes 8vo. In 1750 was published an appendix to

his *Inquiry into the Nature of the Human Soul*, in which he endeavoured to remove some difficulties which had been started against his notions of the *vis inertiæ* of matter, by Maclaurin, in his *Account of Sir Isaac Newton's Philosophical Discoveries*. To this Baxter prefixed a dedication to John Wilkes, with whom he had formed acquaintance abroad. The *Inquiry* is a work of no small ability. The author begins by examining, after the principles of the Newtonian philosophy, the properties of matter. All, save one, result from forces which act on matter. The one essential property of matter is its inacttivity, *vis inertiæ*, or resistance to motion. From this single fact it at once follows that all action or movement must be the effect of some immaterial cause, *i.e.*, of God. The spontaneous motions of the body are not of the same kind as the mechanical movements of the external universe, and are accordingly to be ascribed to a special immaterial force, or spirit, the soul. From the immateriality of the soul its immortality is, of course, deduced. Nor does the conscious existence of the soul depend upon that of the body; it lives after death. Baxter supports his argument by a long analysis of the phenomena of dreams, which he ascribes to direct spiritual influence, and finally attempts to prove that matter is not eternal. A second edition of the *Inquiry* was published in 1737, and a third in 1745.

BAXTER, RICHARD, one of the most eminent of English divines, styled by Dean Stanley "the chief of English Protestant Schoolmen," was born at Rowton in Shropshire, at the house of his maternal grandfather, on November 12, 1615. His family connections were favourable to the growth of piety. But his early education was much neglected, and he did not study at any university, a circumstance worthy of notice, considering the eminent learning to which he afterwards attained. His best instructor was a Mr John Owen, master of the Free School at Wroxeter. His diligence in the acquirement of knowledge was remarkable; and from the first he had a strong bent towards the philosophy with which religion is concerned,—Mr Francis Garbet of Wroxeter being the director of these studies. For a short time his attention was turned to a court life, and he went to London under the patronage of Sir Henry Herbert, master of the revels, to follow that course; but he very soon returned home with a fixed resolve to cultivate the pursuit of divinity. Practical rather than speculative theology seems to have occupied his mind, and he therefore presented himself for ordination without any careful examination of the Church of England system. He was nominated to the mastership of the Free Grammar School, Dudley, in which place he commenced his ministry, having been ordained and licensed by Thornborough, bishop of Worcester. His popularity as a preacher was, at this early period, very great; and he was soon transferred to Bridgnorth, where, as assistant to a Mr Madstard, he established a reputation for the vigorous discharge of the duties of his office.

During this time he took a special interest in the controversy relating to Nonconformity and the English Church. He soon, on some points, became alienated from the Church; and after the requirement of what is called "the *et cetera* oath," he rejected Episcopacy in its English form. He could not, however, be called more than a moderate Nonconformist; and such he continued to be throughout his life. Though commonly denominated a Presbyterian, he had no exclusive attachment to Presbyterianism, and often manifested a willingness to accept a modified Episcopalianism. All forms of church government were regarded by him as subservient to the true purposes of religion.

One of the first measures of the Long Parliament was to effect the reformation of the clergy; and, with this view, a committee was appointed to receive complaints against them. Among the complainants were the inhabitants of Kidderminster, a town which had become famous for its ignorance and depravity. This state of matters was so clearly proved that an arrangement was agreed to on the part of the vicar, by which he allowed £60 a year, out of his income of £200, to a preacher who should be chosen by certain trustees. Baxter was invited to deliver a sermon before the people, and was unanimously elected as the minister of the place. This happened in 1641, when he was twenty-six years of age.

His ministry continued, with very considerable interruptions, for about nineteen years; and during that time he accomplished a work of reformation in Kidderminster and the neighbourhood which is as notable as anything of the same kind upon record. Civilized behaviour succeeded to brutality of manners; and, whereas the professors of religion had been but small exceptions to the mass, the unreligious people became the exceptions in their turn. He formed the ministers in the country around him into an association for the better fulfilment of the duties of their calling, uniting them together irrespective of their differences as Presbyterians, Episcopalians, and Independents. The spirit in which he acted may be judged of from *The Reformed Pastor*, a book published in relation to the general ministerial efforts he promoted. It drives home the sense of clerical responsibility with extraordinary power. The result of his action is that, to this day his memory is cherished as that of the true apostle of the district where he laboured.

The interruptions to which his Kidderminster life was subjected arose from the condition of things occasioned by the Civil War. Worcestershire was a cavalier county, and a man in Baxter's position was, while the war continued, exposed to annoyance and danger in a place like Kidderminster. He therefore removed to Gloucester, and afterwards settled in Coventry, where he for the most part remained about two years, preaching regularly both to the garrison and the citizens. After the battle of Naseby he took the situation of chaplain to Colonel Whalley's regiment, and continued to hold it till February 1647.

His connection with the Parliamentary army was a very characteristic one. He joined it that he might, if possible, counteract the growth of the sectaries in that field, and maintain the cause of constitutional government in opposition to the republican tendencies of the time. He regretted that he had not previously accepted an offer of Cromwell to become chaplain to the Ironsides, being confident in his power of persuasion under the most difficult circumstances. His success in converting the soldiery to his views does not seem to have been very great, but he preserved his own consistency and fidelity in a remarkable degree. By public disputation and private conference, as well as by preaching, he enforced his doctrines, both ecclesiastical and political, and shrank no more from urging what he conceived to be the truth upon the most powerful officers than he did from instructing the meanest followers of the camp. Cromwell shunned his society; but Baxter having to preach before him after he had assumed the Protectorship, chose for his subject the old topic of the divisions and distractions of the church, and in subsequent interviews not only opposed him about liberty of conscience, but spoke in favour of the monarchy he had subverted. There is a striking proof of Baxter's insight into character in his account of what happened under these circumstances. Of Cromwell he says, "I saw that what he learned must be from himself." It is worthy of notice that this intercourse with Cromwell occurred when Baxter was summoned to London to assist in settling "the fundamentals of religion," and made the memorable declaration in answer to the objection, that

what he had proposed as fundamental "might be subscribed by a Papist or Socinian." "So much the better," was Baxter's reply, "and so much the fitter it is to be the matter of concord."

After the Restoration in 1660 Baxter settled in London. He preached there till the Ejectment Act took effect in 1662, and was employed in seeking for such terms of comprehension as would have permitted the moderate dissenters with whom he acted to have remained in the Church of England. In this hope he was sadly disappointed. There was at that time on the part of the rulers of the church no wish for such comprehension, and their object, in the negotiations that took place, was to excuse the breach of faith which their rejection of all reasonable methods of concession involved. The chief good that resulted from the Savoy Conference was the production of Baxter's *Reformed Liturgy*, a work of remarkable excellence, though it was cast aside without consideration. The same kind of reputation which Baxter had obtained in the country he secured in the larger and more important circle of the metropolis. The power of his preaching was universally felt, and his capacity for business placed him at the head of his party. That he should have been compelled by the activity of party spirit to remain outside the National Church is to be deeply regretted. He had, indeed, been made a king's chaplain, and was offered the bishopric of Hereford, but he could not accept the offer without virtually assenting to things as they were; after his refusal he was not allowed, even before the passing of the Act of Uniformity, to be a curate in Kidderminister, though he was willing to serve that office gratuitously. Bishop Morley even prohibited him from preaching in the diocese of Worcester. The whole case illustrates afresh the vindictive bitterness of ecclesiastical factions in the heat of party contests, and especially in the hour of secular triumph.

From the Ejectment of 1662 to the Indulgence of 1687, Baxter's life was constantly disturbed by persecution of one kind or another. He retired to Acton in Middlesex, for the purpose of quiet study, and was dragged thence to prison on an illegal accusation of keeping a conventicle. He was taken up for preaching in London after the licences granted in 1672 were recalled by the king. The meeting-house which he had built for himself in Oxendon Street was closed against him after he had preached there but once. He was, in 1680, seized in his house, and conveyed away at the risk of his life; and though he was released that he might die at home, his books and goods were distrained. He was in 1684 carried three times to the sessions' house, being scarcely able to stand, and without any apparent cause was made to enter into a bond for £400 in security for his good behaviour.

But his worst encounter was with Judge Jeffreys in May 1685. He had been committed to the King's Bench Prison for his *Paraphrase on the New Testament*, which was ridiculously attempted to be turned into a seditious book, and was tried before Jeffreys on this accusation. The scene of the trial is well known as among the most brutal perversions of justice which have occurred in England. Jeffreys himself acted like an infuriated madman; but there were among his blackguardisms some sparks of intelligence.

Mr Rotheram, one of his counsel, said that Baxter frequently attended divine service, went to the sacrament, and persuaded others to do so too, as was certainly and publicly known; and had, in the book charged against him, spoken very moderately and honourably of the bishops of the Church of England. "Baxter for bishops!" Jeffreys exclaimed, "that's a merry conceit indeed; turn to it, turn to it." Upon this, Rotheram read out:—"That great respect is due to those truly called to be bishops among us," or to that purpose. "Ay," said Jeffreys, "this is your Presbyterian cant—truly called to be bishops—that is himself and such rascals, called to be bishops of Kidderminster and other such places, bishops set apart by such factious, snivelling Presbyterians as himself. A Kidderminster bishop he means."

That was sharp, however coarse; for, putting the case vulgarly, it was "a Kidderminster bishop" that Baxter meant. He was sentenced to pay 500 marks, to lie in prison till the money was paid, and to be bound to his good behaviour for seven years. It was even asserted at the time that Jeffreys proposed he should be whipped at the cart's tail through London. The old man, for he was now seventy, remained in prison for two years.

During the long time of oppression and injury which followed the Ejectment, Baxter was sadly afflicted in body. His whole life was indeed one continued disease, but in this part of it his pain and languor had greatly increased. Yet this was the period of his greatest activity as a writer. He was a most voluminous author, his separate works, it is said, amounting to 168. A considerable proportion of these, including folios and quartos of the most solid description, were published by him while thus deprived of the common rights of citizenship. How he composed them is matter of wonder. They are as learned as they are elaborate, and as varied in their subject as they are faithfully composed. Such treatises as the *Christian Directory*, the *Methodus Theologiæ Christianæ*, and the *Catholic Theology*, might each have occupied the principal part of the life of an ordinary man. One earthly consolation he had in all his troubles; he was attended upon by a loving and faithful wife, whom he had married in the Ejectment year. She was much younger than himself, and had been brought up as a lady of wealth and station; but she adhered to him in all his wanderings, sharing his sufferings, and following him to prison; and she has her reward in that *Breviate of the Life of Mrs Margaret Baxter*, which, while it records her virtues, reveals on the part of her husband a tenderness of nature which might otherwise have been unknown.

The remainder of Baxter's life, from 1687 onwards, was passed in peace and honour. He continued to preach and to publish almost to the end. He was surrounded by attached friends, and reverenced by the religious world. His saintly behaviour, his great talents, and his wide influence, added to his extended age, raised him to a position of unequalled reputation. He died in London on the 8th of December 1691, being seventy-six years old, and was buried in Christ Church. His funeral was attended by a very large concourse of people of all ranks and professions, including churchmen as well as dissenters. A similar tribute of general esteem was paid to him nearly two centuries later, when a statue was erected to his memory at Kidderminster in July 1875. On that occasion clergy of all denominations, among whom the bishop of Worcester and the dean of Westminster were conspicuous, took part in the proceedings.

There are few persons of whom we can form a more distinct conception than we can of Richard Baxter. His face is quite familiar to us. His thin and stooping figure we seem to have seen. We can imagine the glance of his piercing eye. Who has not smiled at the intensity of his argumentative nature? He thought every one was amenable to reason—bishops and levellers included. See him contending with the military sectaries in the church at Chesham, from morning to night, when "he took the reading-pew, and Pichford's cornet and troopers took the gallery." Follow him, undeterred by his former want of success, to the church at Bewdley, where he disputed all day with Mr Tombs about infant baptism. Read his correspondence with Dr John Owen relative to the union of Presbyterians with Independents, in which his eagerness amusingly contrasts with Owen's hesitation. Watch him hour after hour in hand-to-hand controversy with Dr

Gunning at the Savoy Conference, when all the town looked at them as at two boxers in a ring. These are but specimens of other like exhibitions. And yet he was as far as possible from being a quarrelsome man. It was in charity for his opponents that he fought. His pertinacity in contention was the fruit of the sincerity of his aims. He must have been a delightful companion to those who shared his religious or scholastic sympathies. How pleasant and profitable it would have been to witness the intimate intercourse at Acton between him and Sir Matthew Hale! He was at once a man of fixed belief and large appreciation, so that his dogmatism and his liberality sometimes came into collision. There was a universality in his genius which distinguishes him from most other men. His popularity as a preacher was deservedly pre-eminent; but no more diligent student ever shut himself up with his books. He was singularly fitted for intellectual debate, but his devotional tendency was equally strong with his logical aptitude. Some of his writings, from their metaphysical subtilty, will always puzzle the learned; but he could write to the level of the common heart without loss of dignity or pointedness. His *Reasons for the Christian Religion* is still, for its evidential purpose, better than most works of its class. His *Poor Man's Family Book* is a manual that continues to be worthy of its title. His *Saints' Everlasting Rest* will always command the grateful admiration of pious readers. Perhaps no thinker has exerted so great an influence upon Nonconformity as Baxter has done, and that not in one direction only, but in every form of development, doctrinal, ecclesiastical, and practical. He is the type of a distinct class of the Christian ministry,--that class which aspires after scholarly training, prefers a broad to a sectarian theology, and adheres to rational methods of religious investigation and appeal. The rational element in him was very strong. He had a settled hatred to fanaticism. Even Quakerism he could scarcely endure. An infusion of ideal sentiment would have been beneficial to the conduct of his life, as well as to his expositions of truth. The ministers of whom he was the type are to be found in all divisions of the Christian church, but with characteristic modifications. Sometimes their rationalism is most distinctive, sometimes their learning, sometimes their sympathetic feeling. But Baxter excels most of the men he thus represents in his union of those qualities, as well as in the intense sense of religion by which he was actuated. Religion was with him all and in all,—that by which all besides was measured, and to whose interests all else was subordinated.

A good *Life of Baxter*, by the Rev. William Orme, was prefixed to his *Practical Works* (published in 23 volumes); Dr Calamy abridged his *Life and Times*. The abridgment forms the first volume of the account of the ejected ministers, but whoever refers to it should also acquaint himself with the reply to the accusations which had been brought against Baxter, and which will be found in the second volume of Calamy's *Continuation*. Sir James Stephen's interesting paper on Baxter, contributed originally to the *Edinburgh Review*, is reprinted in the second volume of his *Essays*. The best recent estimates of Baxter are those given by Principal Tulloch in his *English Puritanism and its Leaders*, and by Dean Stanley in his address at the inauguration of the statue to Baxter at Kidderminster. But most valuable of all is Baxter's autobiography, called *Reliquiæ Baxterianæ, or Mr Richard Baxter's Narrative of the most memorable Passages of his Life and Times.* It is almost as real as a personal knowledge of its subject could have been. The account he gives at the end of Part I. of the spiritual changes he had undergone will never cease to be regarded as a rare and profoundly interesting instance of faithful self-knowledge, and it has served the cause of Christian charity more, probably, than any treatise ever written on the subject.

There are two testimonies to Baxter's worth which, though they have frequently been quoted, cannot be omitted from any fair notice of him. Dr Barrow said that "his practical writings were never mended, and his controversial ones seldom confuted," and Bishop Wilkins asserted that "if he had lived in the primitive time he had been one of the fathers of the church."

BAYARD, PIERRE DU TERRAIL, CHEVALIER DE, was born, of a noble family, at the chateau Bayard, Dauphiné, in 1476. He served as a page to the duke of Savoy until Charles VIII., attracted by his graceful bearing, placed him among the royal followers under the count de Ligny. As a youth he was distinguished for comeliness, affability of manner, and skill in the tilt-yard. In 1494 he accompanied Charles VIII. into Italy, and was knighted after the battle of Fornova, where he had captured a standard. Shortly afterwards, entering Milan alone in pursuit of the enemy, he was taken prisoner, but was set free without a ransom by Ludovic Sforza. His powers and daring were conspicuous in the Italian wars of this period. On one occasion it is said that, single-handed, he made good the defence of a bridge over the Garigliano against about 200 Spaniards, an exploit that brought him such renown that Pope Julius II. sought to entice him into the Papal service, but unsuccessfully. The captaincy of a company in the royal service was given him in 1508, and the following year he led a storming party at the siege of Brescia. Here his intrepidity in first mounting the rampart cost him a severe wound, which obliged his soldiers to carry him into a neighbouring house, the residence of a nobleman, whose wife and daughters he protected from threatened insult. On his recovery he declined a gift of 2500 ducats, with which they sought to reward him. At this time his general was the celebrated Gaston de Foix, who acted greatly in accordance with his advice, and, indeed, fell at the battle of Ravenna through neglecting it. In 1513, when Henry VIII. of England routed the French at the battle of the Spurs, Bayard, in trying to rally his countrymen, found his escape cut off. Suddenly riding up to an English officer who was resting unarmed, he summoned him to yield, and the knight complying, Bayard in return gave himself up to his prisoner. He was taken into the English camp, but on relating this gallant incident was immediately set free by the king without ransom. On the accession of Francis I. in 1515 he was made lieutenant-general of Dauphiné; and after the victory of Marignano, to which his valour largely contributed, he had the honour of conferring knighthood on his youthful sovereign. When war again broke out between Francis I. and Charles V., Bayard, with 1000 men, held Mézières, a town which had been declared untenable, against an army of 35,000, and after six weeks compelled Nassau to raise the siege. This stubborn resistance saved Central France from invasion, as the king had not then sufficient forces to withstand the imperialists. All France rang with the achievement. Parliament thanked Bayard as the saviour of his country; the king made him a knight of the order of St Michael, and commander in his own name of 100 gens d'armes, an honour till then reserved for princes of the blood. After allaying a revolt at Genoa, and striving with the greatest assiduity to check a pestilence in Dauphiné, Bayard was sent, in 1523, into Italy with Admiral Bonivet, who, being defeated at Rebec, implored him to assume the command and save the army. He repulsed the foremost pursuers, but in guarding the rear at the passage of the Sesia was mortally wounded. He had himself placed against a tree that he might die facing the

enemy, and to Bourbon, who came up and expressed pity for him, he replied, "My lord, I thank you, but pity is not for me, who die a true man, serving my king; pity is for you who bear arms against your prince, your country, and your oath." He expired after repeating the *Miserere*. His body was restored to his friends and interred near Grenoble. Chivalry, deprived of fantastic extravagance, is perfectly mirrored in the character of Bayard. He combined the merits of a skilful tactician with the romantic heroism, piety, and magnanimity of the ideal knight-errant. Even adversaries experienced the fascination of his virtues, and joined in the sentiment that he was, as his contemporaries called him, "Le chevalier sans peur et sans reproche." (*Cf.* Walford's *Chevalier Bayard.*)

BAYAZID, or BAJAZID, a city of Turkish Armenia, in the pashalic of Erzeroum, 50 miles S.S.W. of Erivan, situated on the side of a rugged mountain that forms, as it were, a bastion of the Ala-dagh chain. It contains two churches, three mosques, and a monastery, that of Kara Killeesea, which is famous for the beauty of its architecture, as well as for its antiquity and grandeur. The summit of the mountain is occupied by the ruinous *Ak Serai*, or palace, which was built by Mahmoud Pasha. The Pasha's tomb, a work of considerable richness, is in the neighbouring mosque. The position of the town, on the frontiers of Turkey and Persia and on the high road between Armenia and Azerbijan, gives it a certain importance. It was captured by the Russians in 1828 and again in 1854, when they destroyed the fortifications on their departure. The population, which has decreased greatly within the last forty years, now numbers about 5000. Long. 43° 26′ E., lat. 39° 24′ N.

BAYEUX, formerly the capital of the Bessin, and now the chief town of an arrondissement in the department of Calvados, in France. It is situated in a fruitful valley on the River Aure, 17 miles W.N.W. of Caen. Many of its houses are of considerable antiquity, especially in the Rue St Malo and Rue St Nicholas, one in the former street being a fine specimen of the woodwork of the 15th century. The cathedral is a majestic edifice for the most part of the 12th century, though the crypt probably dates from the time of Odo (1047). There are said to be no fewer than 2976 capitals in its construction, all sculptured differently. Bayeux is the seat of a bishopric, and has tribunals of primary jurisdiction and commerce, a communal college, and an extensive library. The former episcopal palace is now the town-house, and the seminary is turned into barracks. The chief manufactures are linen and cotton goods, hosiery, lace, and pottery. Important fairs are held for the sale of horses and cattle. Under the Romans the town bore the name of Augustodurus, and was the seat of a military establishment. During the Middle Ages it was frequently burnt, and passed from one lordship to another till it was incorporated in the duchy of Normandy. Nothing, perhaps, has done more for its fame than the possession of the Norman tapestry, which is now deposited in the town-house. It consists of a strip of linen 200 feet long by 20 inches wide, worked in coloured worsted, and contains fifty-eight distinct scenes connected with the life of William the Conqueror. Seven colours only are employed, dark and light blue, red, yellow, buff, and dark and light green. In spite of the doubts that have been cast on the date of this tapestry, it seems almost certain that it is contemporaneous with the events it depicts, and it may even possibly be, as tradition would have it, the work of Queen Matilda herself. (See Bruce's *Bayeux Tapestry*, 4to, 1855; Freeman's *Norman Conquest*; Macquoid's *Through Normandy*, 1874.)

BAYLE, PIERRE, author of the famous *Historical and Critical Dictionary*, was born on the 18th November 1647, at Carlat-le-Comte, near Foix, in the south of France. He was educated at first by his father, a Calvinist minister, and was afterwards sent to an academy at Puy-Laurens, where he studied with such assiduity as seriously to injure his health. After a short residence at home he entered a Jesuit college at Toulouse. While there he devoted much of his time to controversial works on theology, and ended by abjuring Calvinism and embracing the Roman Catholic faith. In this, however, he continued only seventeen months, abruptly resuming his former religion. To avoid the punishment inflicted on such as relapsed from the Catholic Church, he withdrew to Geneva, where he resumed his studies, and for the first time became acquainted with the philosophical writings of Descartes. For some years he acted as tutor in various families; but in 1675, when a vacancy occurred in the chair of philosophy at the Protestant university of Sedan, he was prevailed upon to compete for the post, and was successful. In 1681 the university at Sedan was suppressed, but almost immediately afterwards Bayle was appointed professor of philosophy and history at Rotterdam. Here in 1682 he published his famous letter on comets, and his critique of Maimbourg's work on the history of Calvinism. The great reputation achieved by this critique stirred up the envy of Bayle's colleague, Jurieu, who had written a book on the same subject, and who afterwards did all in his power to injure his former friend. In 1684 Bayle began the publication of his *Nouvelles de la République des Lettres*, a kind of journal of literary criticism, which was continued with great success for several years. In 1690 appeared a work entitled *Avis aux Réfugiés*, which Jurieu attributed to Bayle, whom he attacked with the bitterest animosity. After a long quarrel Bayle was deprived of his chair in 1693. He was not much depressed by this misfortune, being at the time closely engaged in the preparation of his great Dictionary, which appeared in 1697. A second edition was called for in 1702. The few remaining years of Bayle's life were devoted to miscellaneous writings, arising in many instances out of criticisms made upon his Dictionary. He died on the 28th December 1706, after some months' suffering from chest disease, which he would not permit to interfere with his literary labours. Bayle's erudition, despite the low estimate placed upon it by Leclerc, seems to have been very considerable. He was an ardent student, and his reading was varied and extensive. As a critic he was second to none in his own time, and even yet one can admire the lightness and delicacy of his touch, and the skill with which he handles his subject. The *Nouvelles de la République des Lettres* was the first thorough-going attempt to popularize literature, and it was eminently successful. The Dictionary, however, is Bayle's masterpiece, and in it appear to perfection his various qualities,—extensive and curious information, fluency of style, and that light sceptical spirit which has became closely associated with his name. Bayle's scepticism is of a peculiar kind. It is not a distrust of the power of human knowledge grounded on a scientific investigation of the nature of thought in itself. It is rather the scepticism of the literary man of the world, who in his reading has encountered so many opposing and well-supported arguments on all subjects, that he feels inclined to hold that no certainty can ever be attained. On this account, perhaps, his sceptical criticism, though it did much to liberate thought from the bonds of authority, has had little influence on pure philosophy. Examples of Bayle's critical mode of investigation may be seen in his articles on the Greek sceptical philosophers, particularly those on Pyrrhonism, Zeno, Carneades, and Chrysippus.

See Des Maizeaux, *Vie de Bayle*; Feuerbach, *Pierre Bayle*, 1838; Damiron, *Philosophie en France au xviiime Siècle*.

BAYONET. See ARMS AND ARMOUR, vol. ii. p. 558.

BAYONNE, probably the ancient *Lapurdum*, *Baiotium civitas*, or *Baioticum*, a first-class fortified city of France, and the capital of an arrondissement, in the department of the Lower Pyrenees. It is well built, and agreeably situated at the confluence of the Nive and Adour, about three miles from the sea. A bar at the mouth of the river, with 13 or 15 feet of water at spring tides and 9 to 11 feet at neaps, formerly prevented large vessels from entering except at high water; but works have been in progress by which the obstruction will be greatly lessened, if not altogether removed. The citadel is one of the finest works of Vauban, and the cathedral is a large and elegant Gothic structure of the 12th century. Bayonne is the seat of a bishopric, and has courts of primary jurisdiction and commerce, an exchange, a mint, a theatre, naval and commercial docks, and schools of commerce and navigation, as well as distilleries, sugar-refineries, and glass-works. It is likewise the centre of the 13th military division, and possesses one of the finest arsenals in France, and a military hospital for 2000 patients. Its export trade is considerable, particularly in grain, wire, fish, chocolate, liqueurs, cream of tartar, hams, rosin, turpentine, and timber. The Nive and Adour divide the town into three nearly equal parts, communicating with each other by bridges. Great Bayonne, which lies on the left bank of the Nive, contains the old castle; Little Bayonne, where the new castle stands, is situated between the Nive and the Adour; and Saint Esprit, formerly a suburb, occupies the right bank of the Adour. The last is inhabited almost exclusively by Jews. Bayonne, though often besieged, has never been taken, and is one of the few places that refused to participate in the massacre of St Bartholomew. The last siege was by the English in 1814, and was interrupted by the news of Napoleon's surrender. The bayonet derives its name from this place, where it is said to have been invented. Population in 1872, 26,335.

See Balasque and Dulaurens, *Études Historiques sur la ville de Bayonne*, 3 vols., which treats of the history down to 1451.

BAZA (the mediæval *Bastiana*), a city of Spain in the province of Granada, situated in a fruitful valley in the Sierra Nevada, not far from the river of its own name. In the time of the Moors it was one of the three most important cities in the kingdom of Granada, carrying on an extensive trade, and numbering no fewer than 50,000 inhabitants. It was captured by the Spaniards in 1489 after a seven months' siege. The city still contains various remains of Moorish architecture, as well as its ancient church, which had been converted into a mosque; and in the neighbouring plain have been discovered from time to time numerous relics of antiquity, both Roman and mediæval. The principal trade of the place is at present in hemp; its population numbers 7270. It is the birthplace of Ribera, the historian of Granada. In 1810 Soult defeated a large Spanish army in the immediate vicinity.

BAZARD, ARMAND, a French socialist, the founder of a secret political society in France, corresponding to the Carbonari of Italy, and a warm adherent of St Simon, was born at Paris in 1791. He took part in the defence of Paris in 1815, and afterwards occupied a subordinate situation in the prefecture of the Seine. About the year 1820 he united some patriotic friends into a society, which was called *Amis de la Vérité*. From this was developed a complete system of Carbonarism, the peculiar principles of which were introduced from Italy by two of Bazard's friends. Bazard himself was at the head of the central body, and, while taking a general lead, contributed extensively to the Carbonarist journal, *L'Aristarque*. An unsuccessful outbreak at Belfort ruined the society, and the leaders were compelled to conceal themselves. Bazard, after remaining for some time in obscurity in Paris, came to the conclusion that the ends of those who wished well to the people would be most easily attained, not through political agitation, but by effecting a radical change in their social condition. This train of thinking naturally drew him towards the socialist philosophers of the school of St Simon, whom he joined. He contributed to their journal, *Le Producteur;* and in 1828 began to give public lectures on the principles of the school, which were well attended. His most important work, however, was the first volume of the *Exposition de la Doctrine de St Simon* (2 vols., 1828–30), by far the best account of that peculiar phase of socialism. The second volume was chiefly by Enfantin, who along with Bazard stood at the head of the society, but who was superior in metaphysical power, and was prone to push his deductions to extremities. The two leaders differed in opinion with regard to the emancipation of women, which Bazard disapproved. An open quarrel took place in 1831, and Bazard found himself almost deserted by the members of the society. He attacked Enfantin violently, and in a warm discussion between them he was struck down by apoplexy. After lingering for a few months he died on the 29th July 1832.

BÁZÍGARS, a tribe of Indians, inhabiting different parts of the peninsula of Hindustán. They are recognised by several appellations, as Bázígars, Panchpíri, Kunjrá, or Nats; they follow a mode of life distinguishing them from the Hindus, among whom they dwell; they abstain from intermixing their families with the Hindus, and from any intercourse by which they can be united. They are dispersed throughout the whole of India, partly in wandering tribes, partly adhering to fixed residences, but the greater proportion lead a nomadic life.

The Bázígars are divided into seven castes; but besides those who are united into sects or castes, there are individuals who wander about endeavouring to pick up a precarious livelihood. Although the Bázígars are distinguished by their manners and customs from the natives of Hindustán, their features do not certainly discriminate them as a separate race. Some of their women are reputed very beautiful, and are thence sought after in those temporary alliances common in the East. The Bázígars more especially distinguished by that name are the most civilized of the whole; they are Mahometans in food, apparel, and religion. The Panchpíri profess no system of faith, in preference adopting indifferently that of any village whither their wanderings may guide them. Some traverse the country as Mahometan fakírs, and live on the chance bounty of devotees; and a particular association among them, of bad repute or abject superstition, has been accused of sacrificing human victims. The chief occupation of the Bázígars seems to consist in feats of address and agility to amuse the public, in which both males and females are equally skilful. The former are extremely athletic, and the women are taught dancing, which, instead of the graceful motions seen in the north, consists principally of a display of lascivious gestures. Most of the men are adroit jugglers, tumblers, and actors. Both males and females pursue a systematic course of debauchery, so that few live beyond forty, and many do not attain their thirtieth year. From the pursuits of the females being productive to their parents, their marriages are deferred to a later period than is usual in India. The females who do not attend the juggling exhibitions of the men, or their feats of activity, practise physic and cupping, and perform a kind of tattooing on the skin of the Hindus of their own sex, called *godná*. The men, besides their usual occupations, collect medical herbs, which are prepared by their wives as curatives, especially of the complaints of their own sex. In this manner, or by the sale of trinkets, they find employment in the towns,

though these occupations afford them but a precarious subsistence. Some tribes also go about exhibiting wild beasts, or offering for sale mats fabricated by themselves. Before the establishment of the British Government in Bengal, the Bázígars were subject to the arbitrary exactions of a tax-gatherer, whom they greatly dreaded, and the apprehension of the renewal of that officer's powers has proved a considerable impediment to investigating their manners and customs.

The Bázígars are supposed to present many features analogous to the gipsies scattered over Europe and Asia, where they subsist as a race distinct from all the other inhabitants of the countries frequented by them. The Bázígars, as well as the gipsies, have a chief or king; each race has a peculiar language, different from that of the people among whom they reside; and the analogy of the languages is so decided, that it is difficult to deny that they have had a common origin. Another resemblance, which has probably been lost in the lapse of time, is supposed to consist in the three-stringed viol introduced into Europe by the jugglers of the 13th century, which is exactly similar to the instrument now used in Hindustán. Disjoined, these analogies may not carry conviction of the identity of the European gipsies with the Indian Bázígars; but, on combining the whole, it does not seem unlikely, that if Asia was their original country, or if they have found their way from Egypt to India, they may also have emigrated farther at a period of remote antiquity, and reached the boundaries of Europe.

BAZZI, GIOVANNI. See SODDOMA.

BDELLIUM, a fragrant gum-resin of a dark-reddish colour, bitter and pungent to the taste. It is closely allied to myrrh, and like it is produced from one or more species of *Balsamodendron*,—the Googul resin, or Indian bdellium, yielded by *B. mukul*, being considered by Dr Birdwood to be the bdellium of Scripture, and the βδέλλιον of Dioscorides. Bdellium is little imported into Europe, but it is extensively used in Indian pharmacy, both human and veterinary; and it is, like myrrh, employed for incense in temples. A variety of the gum-resin known as African bdellium is produced on the East African coast, but nothing is certainly known regarding its botanical source.

BEACHY HEAD, a promontory on the coast of Sussex, between Hastings and Brighton, near which the French defeated the English and Dutch fleet in 1690. It consists of a perpendicular chalk cliff 530 feet high. A lighthouse, with a revolving light 285 feet above high-water mark, was erected in 1828 on the second cliff to the westward, in long. 0° 1′ E., lat. 50° 44′ N.

BEACONSFIELD, a market-town in the county of Buckingham, 23 miles from London, on the road to Oxford. It consists of four streets crossing each other at right angles, and before the opening of the railways was rather a busy place. At one time, indeed, it was the seat of a considerable manufacture of ribbons. The poet Waller and Edmund Burke lived in the neighbourhood, and both are buried in the town. Beaconsfield gave the title of viscountess to the late wife of the Right Hon. B. Disraeli. Population of parish in 1871, 1524.

BEAD, a small globule or ball used in necklaces, and made of different materials, as pearl, steel, garnet, coral, diamond, amber, glass, rock-crystal, and seeds. The Roman Catholics make great use of beads in rehearsing their *Ave-Marias* and *Pater-nosters*, and a similar custom obtains among the religious orders of the East. A string of such beads is called a rosary. Glass beads were used by the Spaniards to barter with the natives of South America for gold when they first established themselves on that continent, and to this day they are a favourite article of traffic with all savage nations. Beads of glass are sent in enormous quantities to Zanzibar, and to all other ports from which a trade with the interior of Africa is carried on, as they form almost the only convenient medium of exchange with the native tribes. The qualities and varieties recognized in the Zanzibar market are said to number more than 400, and the trade there is almost entirely in the hands of the Banyans. Large quantities are also sent to India, the Eastern Archipelago, and the Polynesian Islands; and in the more primitive parts of Europe beads are in considerable demand. Under the name of bugles, a very great quantity of small, mostly cylindrical, beads are used in lace-making, and for the ornamentation of ladies' dresses, the demand in this form fluctuating greatly according to the demands of fashion. Venice is the principal centre of the manufacture of glass beads of all kinds. The exports therefrom during the ten years ending with 1871 amounted to 313,201 quintals, of the value of 61,240,296 Italian lire. In the manufacture of ordinary beads, as conducted at Venice, rods or canes of glass of the colour and quality desired first are drawn out, either pierced or unpierced. The rods may either be of transparent glass, or of opaque coloured enamel glass (*smalti*), or may have complex patterns produced by the twisting of threads of coloured glass through a transparent body, characteristic of Venetian glass. From these rods rounded beads are pinched off, and the more costly kinds, made in imitation of precious stones, &c., are cut and faceted. Imitation pearls, the making of which forms an important part of the bead industry, are blown by the blow-pipe from a milky-white glass. The pearly lustre is communicated by the infiltration of a substance obtained from the scales of the bleak *Leuciscus alburnus*. The more costly imitation pearls receive several coats of the pearly substance, and have weight and solidity added by filling up the interior of the pearl with wax. Gold, silver, and various coloured lustres are frequently substituted for the pearly substance in the manufacture of blown beads.

BEAN, the seed of certain leguminous plants cultivated for food all over the world, and furnished chiefly by the genera *Faba*, *Phaseolus*, *Dolichos*, *Cajanus*, and *Soja*. The common bean, in all its varieties, as cultivated in Britain and on the continents of Europe and America, is the produce of the *Faba vulgaris*. The French bean, kidney bean, or haricot, is the seed of the *Phaseolus vulgaris*; but in India several other species of this genus of plants are raised, and form no small portion of the diet of the inhabitants. From the genus *Dolichos*, again, the natives of India and South America procure beans or pulse, of no small importance as articles of diet, such as the *D. ensiformis*, or sword bean of India, the Lima beans, &c. Besides these there are numerous other pulses cultivated for the food both of man and domestic animals, to which the name beans is frequently given. The common bean is even more nutritious than wheat; and it contains a very high proportion of nitrogenous matter under the form of legumin, which amounts on an average to 24 per cent. It is, however, a rather coarse food, and difficult of digestion, and is chiefly used to feed horses, for which it is admirably adapted. In England French beans are chiefly, almost exclusively, used in the green state; the whole pod being eaten as a table vegetable, or prepared as a pickle. It is wholesome and nutritious; and in Holland and Germany the pods are preserved in salt by almost every family for winter and spring use. The green pods are cut across obliquely, most generally by a machine invented for the purpose, and salted in barrels. When wanted for use they are steeped in fresh water to remove the salt, and broiled or stewed; they form an agreeable addition to the diet at a time when no other vegetable may be had. Under the name of carob beans or locusts, the legume of *Ceratonia siliqua* is cultivated on the shores of the Mediterranean,

and used as food for cattle. The shells of the carob bean contain a large proportion of sugar, and are often consumed as a dainty by children. These beans were formerly supposed to be the locusts eaten by John the Baptist, and hence have been called St John's bread. The Tonka, or Tonquin bean, is the produce of *Dipterix odorata*, a leguminous seed with a fine odour, used in perfumery and largely for scenting snuff. The Calabar ordeal bean is a highly poisonous leguminous seed. There are also several non-leguminous seeds to which the popular name bean is attached. Among these may be mentioned the sacred Egyptian or Pythagorean bean (*Nelumbium speciosum*), and the Ignatius bean (probably *Strychnos multiflora*), a source of strychnine. For the cultivation, &c., of the common bean, see AGRICULTURE, vol. i. p. 360. The ancient Greeks and Romans made use of beans in gathering the votes of the people, and for the election of magistrates. A white bean signified absolution, and a black one condemnation. Beans had a mysterious use in the *lemuralia* and *parentalia*, where the master of the family, after washing his hands three times, threw black beans over his head nine times, continuing to repeat the words, "I redeem myself and my family by these beans."

BEAR, the common name of the *Ursidæ*, a typical family of Plantigrade Mammals, distinguished by their massive bodies, short limbs, and almost rudimentary tails. With the single exception of the Honey Bear, all the species have forty-two teeth, of which the incisors and canines closely resemble those of the purely carnivorous mammals; while the molars, and especially that known as the "carnassial," have their surfaces tuberculated so as to adapt them for grinding vegetable substances. As might have been supposed from their dentition, the bears are truly omnivorous; but most of the family seem to prefer vegetable food, including honey, when a sufficient supply of this can be had. The Grizzly Bear, however, is chiefly carnivorous; while the Polar Bear, in a state of nature, is believed to be almost wholly so. The strength and ferocity of different species and of different individuals of the same species seem to depend largely on the nature of their diet,—those restricted to purely vegetable food showing an approach to that mildness of disposition characteristic of herbivorous animals.

Bears are five-toed, and are provided with formidable claws, but these are not retractile as in the cats, and are thus better fitted for digging and climbing than for tearing. Most of the bears climb trees, which they do in a slow, lumbering fashion, and, in descending, always come hindquarters first. The Grizzly Bear is said to lose this power of climbing in the adult state. In northern countries the bear retires during the winter season into caves and the hollows of trees, or allows the falling snow to cover it, where it remains dormant till the advent of spring, about which time the female usually produces her young. These are born naked and blind, and it is commonly five weeks before they see, or become covered with hair. Before hibernating they grow very fat, and it is by the gradual consumption of this fat—known in commerce as bear's grease—that such vital action as is necessary to the continuance of life is sustained.

The bear family is widely distributed, being found in every quarter of the globe except Australia, and in all climates, from the highest northern latitudes yet reached by man to the warm regions of India and Malaya. In the north-west corner of Africa the single representative of the family found on that continent occurs. Of the remaining species described in Gray's recent monograph of this family, three are European, six American, and eight Asiatic; while one species—the Polar Bear—is common to the Arctic regions of both hemispheres. In addition to these, the best known species are peculiarly rich in varieties. Bears have been recently divided into three groups,—sea bears, land bears, and honey bears.

(1.) Sea bears, of which the Polar or White Bear (*Thalassarctos maritimus*) is the only species known, are distinguished from the other groups by having the soles of the feet covered with close-set hairs,—a beautiful instance of special adaptation to the wants of the creature, the bear being thereby enabled to walk more securely on the slippery ice. In the whiteness of its fur also, it shows such an assimilation in colour to that of surrounding nature as must be of considerable service in concealing it from its prey. The food of the White Bear consists chiefly of seals and fish, in pursuit of which it shows great power of swimming and diving, and a considerable degree of sagacity. It also feeds on the carcases of whales, and on birds and their eggs, and is said to eat berries when these can be had. That it can sustain life on a purely vegetable diet is proved by instances on record of its being fed for years on bread only, in confinement. These bears are strong swimmers, Captain Sabine having found one "swimming powerfully forty miles from the nearest shore, and with no ice in sight to afford it rest." They are often carried on floating ice to great distances, and to more southern latitudes than their own, no fewer than twelve Polar bears having been known to reach Iceland in this way during one winter. The female always hibernates, but the male may be seen abroad at all seasons. In bulk the White Bear exceeds all other members of the family, measuring nearly 9 feet in length, and often weighing 1600 lb.

(2.) Land bears have the soles of the feet destitute of hair, and their fur more or less shaggy. Of these the Brown Bear (*Ursus arctos*,—Ἄρκτος of Aristotle) is found in one or other of its varieties all over the temperate and north temperate regions of the eastern hemisphere, from Spain to Japan. Its fur is usually of a brownish colour, but there are black, blackish-grey, and yellowish varieties. It is a solitary animal, frequenting the wooded parts of the regions it inhabits, and living on a mixed diet of fruits, vegetables, honey, and the smaller animals. In winter it hibernates, concealing itself in some hollow or cavern. It does not seek to attack man; but when baited, or in defence of its young, it shows great courage and strength, rising on its hind legs and endeavouring to grasp its antagonist in an embrace. Bear-baiting, till within comparatively recent times, was a favourite sport throughout Europe, but along with cock-fighting and badger-baiting, has gradually disappeared before a more humane civilization. It was a favourite pastime among the Romans, who imported their bears from Britain, a proof that the animal was then comparatively abundant in that country; indeed, from reference made to it in early Scottish history, the bear does not appear to have been extirpated in Britain before the end of the 11th century. It is now found in greatest abundance in Norway, Russia, and Siberia, where the bear hunt is the favourite sport, and where, when dead, its remains are highly valued. Among the Kamchatkans "the skin of the bear," says a traveller, "forms their beds and their coverlets, bonnets for their heads, gloves for their hands, and collars for their dogs. The flesh and fat are their dainties. Of the intestines they make masks or covers for their faces, to protect them from the glare of the sun in the spring, and use them as a substitute for glass, by extending them over their windows. Even the shoulder-blades are said to be put in requisition for cutting grass." In confinement the Brown Bear is readily tamed; and advantage has been taken of the facility with which it can sustain itself on the hind feet to teach it to dance to the sound of music. It measures 4 feet in length, and is about 2½ feet high.

The American Black Bear (*Ursus americanus*) occurs

throughout the wooded parts of the North American continent, whence it is being gradually driven to make room for man. It is similar in size to the Brown Bear, but its fur is of a soft even texture, and of a shining black colour, to which it owes its commercial value. At the beginning of the present century Black Bears were killed in enormous numbers for their furs, which at that time were highly valued. In 1803 the skins imported into England numbered 25,000, but the imports have since decreased to one-half of that number. They are chiefly used for military accoutrements. This is a timid animal, feeding almost solely on fruits, and lying dormant during winter, at which period it is most frequently killed. It is an object of superstitious reverence to the Indians, who never kill it without apologizing and deploring the necessity which impels them to do so.

The Grizzly Bear (*Ursus ferox*) approaches the Polar Bear in size, while it exceeds that, and all other American mammals, in ferocity of disposition and in muscular strength. It is said to attack the bison, and has been known to carry off a carcase weighing 1000 ℔ for a considerable distance to its den, there to devour it at leisure. It also eats fruit and other vegetables. Its fur is usually of a yellowish brown colour, coarse and grizzled, and of little value commercially, while its flesh, unlike that of other bears, is uneatable even by the Indians. It is found in greatest abundance on the eastern slopes of the Rocky Mountains. The Syrian Bear (*Ursus syriacus*) occurs on Mount Lebanon and throughout Syria, and is probably the species mentioned in Scripture as having destroyed the "forty-and-two children" who mocked Elisha. It is of a dirty yellowish colour, and feeds mainly on vegetables. The Bruang or Malayan Bear (*Helarctos malayanus*) is of a jet black colour, with a white semilunar mark on the chest, and attains a length of 4½ feet. Its food consists almost solely of vegetables and honey, but the latter is its favourite food,—the extreme length and pliability of the tongue enabling it to scoop out the honey-combs from the hollows of trees. It is found in the Malay Peninsula and Islands, and is readily tamed.

(3.) Honey bears are distinguished from the other groups by the absence of two upper incisors, and the very extensile character of the lips. Of these there is but one species, the Sloth or Honey Bear (*Melursus labiatus*). This animal, from its striking outward resemblance to a sloth, was, when first brought to this country, described as a species of *Bradypus*. It is about the size of the Brown Bear, is covered with long, black hair, and is of extremely uncouth aspect. It inhabits the mountainous regions of India, is readily tamed, and is the bear usually exhibited by the Hindoo jugglers. It feeds on fruits, honey, and white ants.

Fossil remains of extinct bears first occur in strata of the Pliocene age. Those of the Great Cave Bear (*Ursus spelæus*), found abundantly in certain caverns of Central Europe and Asia, show that it must have exceeded in size the Polar Bear of the present day. Its remains are also found in similar situations in Britain associated with those of an allied species (*Ursus priscus*).

BEAR LAKE, Great, an extensive sheet of fresh water in the north-west of Canada, between 65° and 67° N. lat., and 117° and 123° W. long. It is of a very irregular shape, has an estimated area of 14,000 square miles, and is upwards of 200 feet above the sea. The Bear Lake River carries its waters into the Mackenzie River.

BEARD. The tradition that Adam was created with a beard (which may be described as bushy rather than flowing), is recorded on ancient monuments, and especially on an antique sarcophagus, which is one of the ornaments of the Vatican. The Jews, with the Orientals generally, seem to have accepted the tradition for a law. The beard was a cherished and a sacred thing. Israel brought it safe out of the bondage of universally shaven Egypt, and the beard was the outward and visible sign of a true man. To rudely touch his beard was to cruelly assail his dignity. Children and other kinsfolk might gently touch it as a sign of love; a fugitive might reverentially raise his hand to it when praying for succour; and he who put his hand on his own beard and swore by it bound himself by the most solemn of oaths, to violate which would render him infamous among his fellow-men. To touch the beard in the allegiance of love established peace and trustfulness between the two parties. When Joab went in to Amasa he took the beard of the latter to kiss him, saying the while, "Art thou in health, my brother?" Therefore it was that Amasa took no heed of the sword in Joab's hand, which Joab at once thrust beneath the other's fifth rib. The Scriptures abound with examples of how the beard and its treatment interpreted the feelings, the joy, the sorrow, the pride, or the despondency of the wearer.

Although the Jews carried their beards with them from their bondage in Egypt, the Egyptians were not at all insensible of the significance of that appendage. They did not despise the type of manhood. Accordingly, on days of high festival they wore false beards, as assertions of their dignity in the scheme of creation, and they represented their male deities with beards "tip-tilted" at the ends. The general reader having laudable curiosity on this matter may be safely referred to the pages of Herodotus,—a writer who had much to say pertinently to the subject, and who, after being maligned as the second father of lies, is now praised for his modesty, and relied on for his trustworthiness.

The modern Mahometans, especially those who have most come in contact with Europeans, have a good deal fallen away from old conservative ideas respecting the beard. Once, this glorious excrescence, as it was held to be, was made, by the followers of Islam, a help to salvation. The hairs which came from it in combing were preserved, broken in two, and then buried. The breaking was a sort of stipulation with some angel who was supposed to be on the watch, and who would look to the safe passage of the consigners of the treasure into the paradise of never-failing sherbet and ever-blooming houris. The first sultan who broke through the orthodox oppression of beardedness was Salim I. (1512–20). This act was a violent shock to the whole body of the faithful, and especially of the Mufti. The very highest priest alone could dare to remonstrate with so absolute a monarch. Salim put aside the remonstrance with a joke. "I have cut off my beard," he said, "in order that my vizier may have nothing to lead me by!" But a crafty minister can find on the face of the most beardless and cruel of despots wherewithal to lead him in the way the minister would have him go. Still, the fact that the Prophet never let razor reap a harvest on his chin, for possession of the hairy produce of which all Islam would have fought with affectionate fury, long made, and still makes, the beard a part of religion. The sultan and the shah, chiefs of the two parties in their church, have pretty fair apologies for beards; but this is far below the bearded glories of the days before the Prophet, when the kings of Persia tied up their bearded plaits with gold thread, and the princes of Nineveh went abroad with beards curled and oiled, like the Assyrian bulls themselves. It has been said that in Asia wars have been proclaimed on alleged grievances connected with shaving. Tartars and Persians, and Chinese and Tartars, are reported to have resorted to sanguinary arbitration on the question of clipping or shaving. Probably they who declared the war were as clever in finding a pretext as the more civilized aggressors of much later days.

If we turn to Europe and begin with classical times, having—

> the wealth of Ormus and of Ind,
> Or where the gorgeous East, with richest hand,
> Showers on her kings barbaric pearl and gold,—

we may remember that the Greeks and Romans once styled as barbarians, or bearded, unshaven savages, all nations who were out of the pale of their own customs and religion. Nevertheless, the young Roman, anxious for beard and moustache, used to apply the household oil to his chin and cheeks, in order to bring thereon that incipient fringe which would entitle him to be called "barbatulus." The full-furnished man was "barbatus." It was not till the beard ceased to be universally worn, and Sicilian barbers set up in Rome (about 300 B.C.), that the Romans began to apply the word, translated "barbarous," to the rude men and manners of the early ages, and of the beard universal. But, after all, we may still see, in old counterfeit presentments, that the fashionable, clipped beard of young Roman "swells" in the last days of the Republic, and of some of the emperors from the time of Hadrian, is not nearly so majestic as the flowing hair depending from the chin of Numa Pompilius. Nero offered some of the hair of his beard to Jupiter Capitolinus, who could have furnished a dozen emperors from his own. Homer, Virgil, Pliny, Plutarch, Strabo, Diodorus, Juvenal, Persius, are among the writers who furnish material for a volume on beards. One Roman emperor, Julian, wrote a work on the subject, which is commonly supposed to be as fierce a denunciation against beards, as King James's *Blast* was against tobacco; but Julian in his *Misopogon*, or *Enemy of the Beard*, descants satirically "with pleasure and even with pride," says Gibbon, "on the length of his nails and the inky blackness of his hands, protests that although the greatest part of his body was covered with hair, the use of the razor was confined to his head alone, and celebrated with visible complacency the shaggy and *populous* beard which he fondly cherished, after the example of the philosophers of Greece." Persius undoubtedly associated wisdom with the beard. He exhausted the whole vocabulary of praise when he designated Socrates by the term *Magister Barbatus*. In this, however, there is less wit than in the rejoinder of the young ambassador to a king, who had expressed his wrath at having a beardless youth sent to him as an envoy. "If," said the latter, "my master had thought you would have laid so much account on a beard, he would have sent you a goat."

The most notable circumstance in the history of the beard among the Greeks is that of its abolition,—in the Macedonian army, at least, for strategic reasons. Alexander the Great abolished the beards of his soldiers, for the sufficient reason that they gave handles to their enemies whereby to lay hold of them. The Macedonian warriors probably obeyed with reluctance; but obedience was as much a matter of course as it was with the Ephori who, by Lacedæmonian law, had to undergo what seemed the ridiculous ceremony of being shaved, merely to show their ready obedience to legal enactment. As they were mortal men, it may be supposed that acquisition of office was happy compensation for the loss of a beard.

Goth is equivalent for the older term of *Barbarian*. One is about as unjust in its application as the other. Gothic rudeness is often illustrated by the case of the "ugly rush" made by the northern warriors into the Capitol, where the conscript fathers sat in silence and fearlessness, waiting events. One of these unlettered soldiers lifted his hand to the beard of an old legislator, who, taking it for insult, smote the Goth to the ground. Let us do the Goth the justice of believing that, awed by the stern mute majesty of the senators, he raised his hand reverentially to the beard. At all events, the taking it with such prompt and painful action was dearly paid for in the swift retaliation which followed.

If the phrase be not too light for use, we would say that as beards existed before barbers, the Europeans, like all other people, were originally a bearded people. The beard is perhaps more general now in Germany than elsewhere in Europe; and Germany affords an example of the longest beard known, out of fairy story, in the person of the painter Johan Mayo, whose beard was so long that when he stood upright it still trailed on the ground; accordingly, he often doubled it up in his girdle. Germany knows him as John the Bearded, just as it does one of its emperors as Frederick Barbarossa; but many nations, ancient and modern, can boast of men and monarchs who have been nicknamed from their beards.

When Peter the Great levied a tax on Russian beards, he was only following a precedent which once existed in England. Noble chins were assessed at a rouble; your commoner chin at a copec. It caused commotion, and there was much compulsory shaving of those who did not pay. Beards are not now valued in Russia. He who wears one seems to acknowledge that he has no very high place in the social scale. On the other hand, beards were highly treasured in Spain till the time of Philip V., who was unable to cultivate one. As was to be expected, this infirmity set the fashion of affecting the infirmity; but beardless dons were wont to exclaim with a sigh, "Since we have lost our beards, we have lost our souls!" Thus, they unconsciously adopted something akin to the superstition of the Roskolniki, a sect of schismatics who obstinately maintained that the divine image resided in the beard. Portugal was not behind Spain in appreciating the beard. When the Portuguese admiral, Jaun de Castro, borrowed a thousand pistoles from the city of Goa, he lent in pledge one of his whiskers, saying, "All the gold in the world cannot equal this natural ornament of my valour." In these modern days one would not think much of the security of such a material guarantee, nor of the modesty of the admiral who might have the face to offer it.

As Spaniards denuded their chins because their king could not grow a beard, so the French grew beards, long after they had gone out of fashion, because their king found it necessary to do so. Francis the First, having wounded his chin, concealed the ugly scar by covering it with a beard; and all loyal chins forthwith affected to have scars to conceal. But when fashion and loyalty were united the beard was carefully tended. It was not as in the time of the idle, helpless, and long haired kings, who were less potential than their chief officers, when the wild, dirty, and neglected beard was a type of that majesty, made up of shreds and patches, which used to be paraded before the people on a springless cart. Three hairs from a French king's beard under the waxen seal stamped on royal letter or charter, were supposed to add greater security for the fulfilment of all promises made in the document itself. In course of time fashion complimented majesty; a certain sort of moustache was called a "royale," and the little tuft beneath the lower lip was known by the term "imperiale." As a rule, the French chin assumed the appearance of that of the king for the time being. The royal portrait reflects a general fashion from which only the disloyal or the indifferent departed. On the subject of shaving, Talleyrand once drew a fine distinction. Rogers asked him if Napoleon shaved himself. "Yes," replied the statesman; "one born to be a king has some one to shave him; but they who acquire kingdoms shave themselves." Tradition has exaggerated accounts of bearded prisoners in the Bastille, but there was an official there whose duty consisted in

keeping the captives without beards. Some years before the Revolution the celebrated lawyer and political writer Linguet was incarcerated there. On the morning after his being locked up, an individual entered his room who announced himself as the barber of the Bastille. "Very well," said the sharp-witted Linguet, "as you are the barber of the Bastille—rasez-la."

Among the men of whom it was said of old that they would be known by their love for one another, the beard has been a cause of much fierce uncharitableness. The Greek Church, advocating the beard, and the Roman Church, denouncing it, were not more forgetful of ever-blessed charity than the Belgian Reformers, the close-shaven of whom wished the bearded members to be expelled as non-Christians. The tradition concerning the Master whom both proposed to follow was logically pleaded by the wearers of beards. As a general rule, in the earlier time, the man who wore his hair short and his beard long, was accounted as at least bearing the guise of respectability,—looking like a priestly personage. There is a series of medals of the popes at Naples, from Clement VII. (1523–34) to Alexander VIII. (1689–91). All these are bearded. Clement's beard is long and dark; Alexander wears beard and moustaches. Perhaps Clement Giulio de' Medici set the fashion. Certain it is that a few years before, his kinsman, Giovanni de' Medici, Leo X. (1513–22), was always close-shaven, and beards were not to be seen on the chin of Leo's clerics and courtiers.

In the 13th century beards are said to have first come into fashion in England. If we may judge from the 15th century brasses in England, few men of distinction enough to be so commemorated wore beards. Hotspur's fop had his "chin new reaped." In the reign of Henry VIII. the fashion had so revived among lawyers that the authorities of Lincoln's Inn prohibited wearers of beards from sitting at the great table, unless they paid double commons; but in all probability this was before that sovereign ordered (1535) his courtiers to "poll their hair," and he let that crisp beard grow which is familiar to us all. Thence came a fiscal arrangement; beards were taxed, and the levy was graduated according to the condition of the wearer. In the Burghmote Book of Canterbury (quoted in *Notes and Queries*) there is the following entry:—"2nd Ed. vi. The Sheriff of Canterbury and *another* paid their dues for wearing beards, 3s. 4d. and 1s. 8d." In the next reign, and in the year 1555, Queen Mary sent four agents to Moscow; all were bearded, but one of them, a certain George Killingworth, was specially distinguished by a beard 5 feet 2 inches long, at sight of which a smile crossed the grim features of Ivan the Terrible himself. George's beard was thick, broad, and yellow; and, after dinner, Ivan played with it, as with a favourite toy. Most of the Protestant martyrs were burnt in their beards. Sir Thomas More, on the other hand, put his out of the way, as he laid his head on the block, with the innocent joke so well known. Elizabeth introduced a new impost with regard to beards. Every beard of above a fortnight's growth was subject to a yearly tax of 3s. 4d. The rate was as heavy as the law authorizing it was absurd. It was made in the first year of her reign, but it proved abortive. Fashion stamped it out, and men laughed in their beards at the idea of paying for them. The law was not enforced, and the Legislature left the heads of the people alone till much later times, when necessity and the costs of war put that tax on hair-powder which even now contributes a few thousands a year to the British Exchequer. The Vandyke beard, pointed (as Charles the First and the illustrious artist, with most cavaliers, wore it), was the most universally worn for a time. Beaumont and Fletcher, in the *Queen of Corinth*, make allusion, doubtless, to a fashion of wearing moustache and beard, common to the reign of the first James as well as that of Charles.

> "His beard
> Which now he puts i' the posture of a T,—
> The Roman T. Your T beard is the fashion,
> And twofold doth express th' enamoured courtier
> As full as your fork-carving traveller."

John Taylor, the water-poet, notices the T beard, and mentions at least a score of the various ways of wearing beards in his time, not forgetting the contemporary proverb, "Beard natural, more hair than wit." Hudibras, in text and notes, affords numerous illustrations of this subject. The general idea that beards did not come back with the monarchy does not seem to be correct, if the old song (date 1660) is to be trusted—

> "Now of beards there be such a company,
> Of fashions such a throng,
> That 'tis very hard to treat of the beard,
> Tho' it be never so long."

Soon after this time, however, the beard in England was everywhere kept down by the razor. At the close of last century the second Lord Rokeby (Mat. Robineau) endeavoured to restore the fashion. "His beard," says a contemporary, "forms one of the most conspicuous traits of his person." But too short a period had elapsed since Lord George Gordon, the hero of "the Riots," had turned Jew and let his beard grow, to allow of any favour being awarded to an appendage which seemed a type of infamy. To the literature of the beard a remarkable addition was made in the present century by James Ward, R.A., the celebrated animal painter. Mr Ward published a *Defence of the Beard*, on Scriptural grounds; he gave eighteen reasons why man was bound to grow a beard, unless he was indifferent as to offending the Creator and good taste; for the artist asserted himself as much as the religious zealot, and the writer asked, "What would a Jupiter be without a beard? Who would countenance the idea of a shaved Christ!" Mr Ward had what the French call "the courage of his opinions," and wore a beard of the most Jupiter-like majesty. Mr Muntz, M.P. for Birmingham, followed the example, but it was not adopted by many others. A new champion, however, appeared in 1860, but on peculiar ground. "Theologos" expressed his view in the title-page of his work, namely,—*Shaving: a breach of the Sabbath, and a hindrance to the spread of the Gospel.* A carrying out of the views of the writer would lead to the full practice which prevailed among the Essenes, who never did on the Sabbath anything whatever that they were in the regular habit of doing on other days. "Theologos" points out that God gave the beard to man as a protection for his throat and chest; and, he adds, with the most amusing simplicity, "Were the beard in any other position its benefit and purpose might be doubted; but situated where it is, no physiologist will dare to deny its intention." Since this naive assertion was made, the beard, but not as a consequence, has grown into favour; and though not universal, it is at least general, and a familiar sight to us all.

There is a disagreeable branch of the subject, demanding only a passing word, namely, bearded women, hermaphroditic creatures, who have occasionally been found in all conditions of life, from princesses in "marble halls" to objects shown in exhibition-rooms or in vans at country fairs.

> —"You should be women,"

says Macbeth,

> "And yet your beards forbid me to interpret
> That you are so."

Sir Hugh Evans expressed the suspicion which attached to a bearded woman, when he said of Falstaff, disguised as Mother Prat, "By yea and no, I think the 'oman is a witch

indeed; I like not when a 'oman has a great peard; I spy a great peard under her muffler." The detestation with which a bearded woman and a red-haired man were visited in France is almost savagely illustrated in the following old lines:—

"Homme roux et femme barbue
De trente pas loin le salue,
Avecque trois pierres au poing,
Pour t'en aider à ton besoing."

(J. DO.)

BÉARN, formerly a small frontier province in the south of France, now included within the department of Basses-Pyrénées, was bounded on the W. by Soule and Lower Navarre, on the N. by Chalosse, Tursan, and Astarac, E. by Bigorre, and S. by the Pyrenees. Its name can be traced back to the town of Beneharnum, which first appears in the Antonine Itinerary. The population is mainly of Basque origin, with possibly a certain mixture of Greek blood from the ancient colonies of that people. The Basque language, in spite of the diffusion of French, is still maintained in the district; and it is asserted that traces of old Hellenic names are not infrequent. Béarn begins first to take rank as a separate viscounty under Louis the Pious. From its first viscounts, who were descended from the dukes of Gascony, it passed about 1134, by failure of the male line, to the Catalonian family of Moncado; and after the people, who were hostile to all connection with Spain, had several times chosen their own leaders, it passed to the family of Foix, from whom it was transmitted through the houses of Grailly and D'Albret to the Bourbons, who, in the person of Henry IV., made it an apanage of the crown of France. It was not till 1620, however, that it was formally incorporated; and even till 1790 it continued to be governed by its own constitution or system of *Fors*, which only exists in the form in which it was drawn up in 1288, though mention is made of it as early as 1080. The parliament of Béarn consisted of two sections, the first composed of the clergy and the nobles, and the second of mayors and councillors (or *jurats*) from forty-two towns or communities. It met every year, and was always presided over by the Bishop of Lescar. A body of commissioners, called the *abrégé des états*, or epitome of parliament, was selected from the members—twelve from the nobles and twelve from the third estate—for the purpose of deciding any business that might demand attention during the time between the regular sessions. The administration of justice devolved in the last resort on a *cour majour*, or greater court, which was changed by Henry D'Albret into a sovereign council under the presidency of the chancellor of Navarre and Béarn, and afterwards, by Louis XIII., into a *parlement* of the ordinary type. Histories of Béarn have been written by Belloy (1608), Marca (1640), D'Olhagaray (1609), Faget de Baure (1818), Mazure (1839).

BEATON, DAVID, archbishop of St Andrews and cardinal, was a younger son of John Beaton of Balfour in the county of Fife, and is said to have been born in the year 1494. He was educated at the universities of St Andrews and Glasgow, and afterwards studied at Paris. His first preferment was the parsonage of Campsie and the chancellorship of the church of Glasgow, to which he was presented in the year 1519 by his uncle James Beaton, then archbishop of Glasgow. When James Beaton was translated to St Andrews he resigned the rich abbacy of Arbroath in his nephew's favour, under reservation of one half of the revenues to himself during his lifetime. The great ability of Beaton and the patronage of his uncle ensured his rapid promotion to high offices in the church and kingdom. He was sent by King James V. on various missions to France, and in 1528 was appointed keeper of the privy seal. He took a leading part in the negotiations connected with the king's marriages, first with Magdalen of France and afterwards with Mary of Lorraine. At the French court he was held in high estimation by King Francis I., and was presented to the bishopric of Mirepoix in Languedoc, to which he is said to have been consecrated on 5th December 1537. On the 20th of December 1538 he was appointed a cardinal priest by Pope Paul III., under the title of St Stephen in the Cœlian Hill. He was the only Scotsman who had been named to that high office by an undisputed right, Cardinal Wardlaw, bishop of Glasgow, having received his appointment from the Antipope Clement VII. On the death of Archbishop James Beaton in 1539, the cardinal was raised to the primatial see of Scotland. He showed his sense of the additional responsibility he had now undertaken by requesting the Pope to relieve him, to some extent, by the nomination of a suffragan or coadjutor in the diocese of St Andrews; and this was effected by the appointment to that office of William Gibson, dean of Restalrig, who received consecration as titular bishop of Libaria.

Beaton was one of King James's most trusted advisers, and is said to have taken a part in dissuading him from his proposed interview with Henry VIII. at York. On the death of James in December 1542 he attempted to assume office as one of the regents for the infant sovereign Mary, founding his pretensions on an alleged will of the late king; but his claims were disregarded, and the Earl of Arran, head of the great house of Hamilton, and next heir to the throne, was raised to the regency. The cardinal was imprisoned by order of the regent, but after some time was set at liberty. He was subsequently reconciled to Arran, and in September 1543 crowned the young queen at Stirling. Soon afterwards he was raised to the highest office under the regent, that of Chancellor of Scotland, and was appointed legate *a latere* by the Pope. The cardinal, in virtue of the latter dignity and of his primatial authority, claimed precedence over Archbishop Dunbar of Glasgow, even within the precincts of the cathedral of St Kentigern. This led to an unseemly brawl between the attendants of the two archbishops, as set forth in a formal complaint made by the cardinal to the Pope, and related at more length and with characteristic glee by Knox. The attention, however, of the cardinal was directed to matters of more importance than disputes with a brother metropolitan.

The two questions which agitated Scotland at this time were the struggle for ascendency between the supporters of English and French influence, and that between the friends of the hierarchy and the teachers of the Reformed opinions,—questions which frequently became complicated in consequence of the assistance given by France to the bishops, and the encouragement which, for political reasons, the king of England secretly gave to the adherents of the Reformation. In this contest the cardinal supported the interests of France, resolutely opposing the selfish intrigues of King Henry and his party, which had for their object the extinction of the ancient independence of the Scottish kingdom and its subjection to the supremacy of England. Had he been content with this he would have won for himself the gratitude of his countrymen; but his evil deeds as an ecclesiastic made them overlook his patriotic exertions as a statesman. During the lifetime of his uncle he had taken his share in the persecuting policy of the hierarchy, and the same line of conduct was still more systematically adopted after his elevation to the primacy. Having won over the regent to his opinions he became more open and severe in his proceedings. The popular accounts of the persecution are no doubt exaggerated, and it sometimes ceased for considerable periods so far as capital punishments were concerned. When the sufferers were of humble rank

general attention was not much directed to them. It was otherwise when a more distinguished victim was selected in the person of George Wishart. This preacher, whose ecclesiastical opinions resembled those of Patrick Hamilton and Hamilton's teacher, Francis Lambert, returned to Scotland after an absence of several years about the end of 1544. His sermons produced a great effect, and he was protected by several of the barons who were leading men in the English faction. These barons, with the knowledge and approbation of King Henry, were engaged in a plot against the cardinal, in which his assassination was contemplated as the speediest mode of removing the chief obstacle to the influence of England. Of the reality of the plot and the intentions of the conspirators there can be no doubt: whether Wishart was aware of these has been a matter of controversy during the present century. There are strong suspicions against him but no sufficient evidence; and all the presumptions which may be drawn from his personal character are entirely in his favour. The cardinal, though ignorant of the details of the plot, perhaps suspecting Wishart's knowledge of it, and in any event desirous to seize one of the most eloquent supporters of the new opinions, endeavoured, with the aid of the regent, to apprehend him, but was baffled in his efforts for some time. He was at last successful in seizing the preacher, and bringing him a prisoner to his castle of St Andrews. On the 28th of February 1546 Wishart was brought to trial within the cathedral church, before the cardinal and other ecclesiastical judges, the regent declining to take any active part. He defended his opinions with temper and moderation; but as he admitted certain of them which were held by his judges to be heretical, he was condemned to death and burnt.

The persecution of Wishart, and the meekness with which he bore his sufferings, produced a deep effect on the mind of the Scottish people, and the cardinal became an object of general dislike. Those who hated him on other grounds were encouraged to proceed with the design they had formed against him. Naturally resolute and fearless, he seems to have undervalued the strength and character of his enemies, and even to have relied on the friendship of some of the conspirators. He crossed over to Angus, and took part in the magnificent ceremonials of the marriage of his illegitimate daughter with the heir of the Earl of Crawford. On his return to St Andrews he took up his residence in the castle. The conspirators, the chief of whom were Norman Leslie, Master of Rothes, and William Kirkaldy of Grange, contrived to obtain admission at daybreak of the 29th of May 1546, and murdered the cardinal under circumstances of horrible mockery and atrocity. The assassination excited very different feelings among the partisans on either side. The zealous adherents of the Church of Rome, as a matter of course, viewed it as a cruel murder aggravated by sacrilege; the most violent of the Protestant party justified and even applauded it. Those who, without any strong feelings either way, disliked the cardinal on account of his arrogance and cruelty, spoke of the deed as a wicked one, but hardly professed to regret the victim. Ignorant of the treasonable designs of his enemies, viewing him as the champion of ecclesiastical supremacy, and attributing to him all the evils of the unsuccessful war with England, they looked upon his death as an advantage to the Scottish kingdom. The men of that age were too much accustomed to such violent deeds to entertain a great abhorrence of assassination, and such feelings and crimes were not confined to the adherents of the Reformation. A few years afterwards Martinuzzi, the cardinal archbishop of Gran, was murdered by the express command of a Roman Catholic prince, Ferdinand, king of the Romans, brother of the Emperor Charles V.

The character of Beaton has already been indicated. As a statesman he was able, resolute, and in his general policy patriotic. As an ecclesiastic he maintained the privileges of the hierarchy and the dominant system of belief conscientiously, but always with harshness and sometimes with cruelty. The immoralities of the cardinal, like his acts of persecution, were exaggerated by his opponents; but his private life was undoubtedly a scandal to religion and the church, and has only the poor excuse that it was not worse than that of most of his order at the time. The authorship of the writings ascribed to him in several biographical notices rests on no better authority than the apocryphal statements of Dempster. (G. G.)

BEATTIE, JAMES, a Scottish poet and writer on philosophy, was born at Laurencekirk on the 25th October 1735. His father, a small farmer and shopkeeper, died when he was very young; but an elder brother took charge of the boy, and observing his aptitude for learning sent him to Marischal College, Aberdeen, where he gained a bursary. In 1753 he was appointed schoolmaster of Fordoun, at the foot of the Grampian hills, amongst splendid scenery, which impressed itself deeply on Beattie's somewhat poetical mind. In 1758 he obtained a situation as under-master in the grammar school, Aberdeen, and two years later he was made professor of moral philosophy at Marischal College. Here he became closely acquainted with Reid, Campbell, Gerard, and others, who formed a kind of literary or philosophical society, in which speculative questions, above all the views of Hume, were canvassed and criticized. In 1770 Beattie published his *Essay on the Nature and Immutability of Truth*, in which he attacked Helvetius and Hume, and advocated the doctrine afterwards familiarly known as that of Common Sense. The work had an astonishing success, and its author, when on a visit to London in 1773, was received with the greatest honour by the king himself. About the same time he received a pension of £200 a year. In 1773 and 1774 he published the first and second parts of *The Minstrel*, which were received with great favour, and gained for the author a fresh accession of popularity. His later writings are partly literary, such as the *Essays*, 1766; *Dissertations*, 1783, partly philosophical; *Evidences of Christianity*, 1781; *Elements of Moral Science*, 1790–93. Beattie was unfortunate in his domestic life. His wife, whom he married in 1767, was afflicted with insanity, a disease which she appears to have inherited from her mother. Two sons, all his family, died just as they were attaining manhood. The elder, James Hay Beattie, a young man of great promise, who at the age of nineteen had been associated with his father in the professorship, died in 1790. The younger brother died in 1796. Beattie never recovered his second blow. His mind was nearly overthrown by it; his spirit was completely broken, and although he still lectured, he neither wrote nor studied. In 1799 he was attacked with palsy, and continued to suffer from that disease for three years. He died on the 18th August 1803. Beattie's fame rests now solely on his poems. The much celebrated *Essay on Truth* is a work of no philosophic ability, and is disfigured by the violent and intemperate language of the author. His other writings on philosophical subjects, such as the *Elements of Moral Science*, are excessively weak, and have fallen into well-deserved oblivion. *The Minstrel*, however, is a work which will always retain a considerable share of popular favour. The ground-plan is simple and well conceived,—to trace the development of poetic genius in a youth from his earliest years up to the time when he becomes able to take his place as a minstrel. There runs through the poem a fine vein of quiet reflection, interspersed with animated descriptions of natural scenery. The versification is smooth

and melodious. (See *Life of Beattie*, by his friend Sir W. Forbes, 1806.)

BEAUCAIRE (*i.e.*, *Bellum Quadrum*, the beautiful square), a town of France, department of Gard, and arrondissement of Nîmes. Lat. 43° 48′ 32″ N., long. 4° 38′ 50″ E. It is situated on the right bank of the Rhone, opposite Tarascon, with which it is connected by a magnificent suspension-bridge of four spans and 1456 feet in length. The town is generally well built, but has no public buildings worthy of notice, and the streets are narrow and crooked. Its ancient castle of Bellicadro is now in ruins. It gives name to the canal which communicates with the sea, and also connects it with the Languedoc canal, forming part of the line of communication between the Rhone and the Garonne. It is also connected with Nîmes and Alais by a railway opened in 1839. The manufactures are few and unimportant. The town derives its celebrity from the great July fair, which has been held here annually since the 13th (or 14th) century, and to which merchants come from all parts of Europe, and even from Persia and Armenia. The extensive meadow, called Magdalen's, on the banks of the Rhone, is set apart for the gathering, and almost every kind of article, whether of convenience or luxury, is there exhibited. Though the fair is now less frequented than formerly, it is said that still as many as 100,000 persons attend. There are stone quarries in the neighbourhood of the town, and the manufacture of linen and woollen stuffs is carried on. Population in 1872, 7858.

Beaucaire occupies the site of the ancient *Ugernum*, and several remains of the Roman city have been discovered, as well as (in 1734) the road that led from Nîmes. It was a fortress in the Middle Ages, and belonged in succession to the counts of Arles, the archbishops of Arles, the counts of Toulouse, and the viscounts of Narbonne. In the 12th century it is frequently mentioned by the troubadours. Presented in 1215 to Simon de Montfort, it was next year taken possession of by Count Raimund VI.; and in 1226 Louis VIII. made himself master of it. In the wars of the League it suffered severely, and in 1632 its castle was destroyed by Richelieu.

BEAUCHAMP, ALPHONSE DE, French historian and man of letters, was born at Monaco in 1767, and died in 1832. In 1784 he entered a Sardinian regiment of marines, but on the outbreak of war with the French Republic, he refused to fight in what he considered an unjust cause, and was imprisoned for several months. After being liberated he took up his residence in Paris, where he obtained a post in one of the Government offices. On the fall of Robespierre, Beauchamp was transferred to the *bureau* of the minister of police, and charged with the superintendence of the press. This situation opened up to him materials of which he made use in his first and most popular historical work, *Histoire de la Vendée et des Chouans*, 3 vols., 1806. The book, received with great favour by the people, was displeasing to the authorities. The third edition was confiscated; its writer was deprived of his post, and in 1809 was compelled to leave Paris and take up his abode in Rheims. In 1811 he obtained permission to return, and again received a Government appointment. This he had to resign on the Restoration, but was rewarded with a small pension, which was continued to his widow after his death.

Beauchamp wrote extensively for the public journals. His historical and biographical works are numerous and important. The best known of them are :—*Histoire de la Conquête du Pérou*, 1807; *Histoire du Brésil*, 1815; *Histoire de la Révolution du Piémont*, 1823; *Vie de Louis XVIII.*, 1821. The *Mémoires de Fouché* have also been ascribed to him.

BEAUHARNAIS, EUGÈNE DE, step-son of Napoleon I., was born at Paris, September 3, 1781. His father, the Vicomte Alexander de Beauharnais, had been a member of the National Convention, and for some time commanded the republican army of the north. His want of success in the field, however, brought him under the suspicion of the Revolutionary leaders; he was tried on a charge of treason, and was executed on 23d June 1794. After the marriage of Napoleon with the Vicomtesse Josephine Beauharnais, her son Eugène accompanied the army of Italy and acted as aide-de-camp to his step-father, by whom he was treated with the greatest affection and favour. He was rapidly promoted; and after the establishment of the empire, was made prince and viceroy of Italy. In 1806 he was adopted by Napoleon. During the great campaign of 1809 he had the command of the Italian army, and by his skilful conduct materially contributed to the success of the emperor. In 1812 he commanded a corps of the grand army; and after the departure of Napoleon and flight of Murat, had the entire charge of the broken French forces. The disastrous campaigns of 1813 and 1814 deprived him of his viceroyalty, and he retired to Munich, the capital of the king of Bavaria, whose daughter he had married in 1806. There he continued to reside, with the title of duke of Leuchtenberg, till his death in 1824.

BEAUMANOIR, PHILIPPE DE, a distinguished writer on French law, was born in the early part of the 13th century, and died in 1296. The few facts known regarding his life are to be gathered from legal documents in which his name occurs. From these it appears that in 1273 he filled the post of *bailli* at Senlis, and in 1280 held a similar office at Clermont. He is also occasionally referred to as presiding at the assizes held at various towns. His great work is entitled *Coutumes de Beauvoisis*, and was first published by De la Thaumassière in 1690. A second edition, with introduction, was published by Beugnot in 1842. It is regarded as one of the best works bearing on old French law, and was frequently referred to with high admiration by Montesquieu.

BEAUMARCHAIS. PIERRE AUGUSTIN CARON, better known by his acquired title DE BEAUMARCHAIS, the most distinguished French comic dramatist next to Molière, and a man of much importance during the pre Revolutionary period, was born at Paris in 1732. His father, who was a watchmaker, brought him up to the same trade. He was an unusually precocious and lively boy, shrewd, sagacious, and, like his sisters, passionately fond of music, and imbued with a strong desire for rising in the world. At the age of twenty-one he invented a new escapement for watches, which was pirated by a rival maker. Young Caron at once published his grievance in the newspapers, and had the matter referred to the Academy of Sciences, who decided in his favour. This affair brought him into notice at court; he was appointed, or at least chose to dub himself, watchmaker to the king, who had called him in to examine Mme. de Pompadour's watch. His handsome figure and cool assurance soon began to make their way at court, where he so earnestly desired to obtain a footing. Nor was it long before his wish was accomplished. The wife of an old court official, conceiving a violent passion for young Caron, persuaded her husband to make over his office to his rival, and on her husband's death, a few months later, married the handsome watchmaker. Caron at the same time assumed the title De Beaumarchais; and four years later, by purchasing the office of secretary to the king, obtained a title of nobility.

While employed at court his musical talents brought him under the notice of the king's sisters, who engaged him to teach them the harp. In this way he obtained access to the best society of the court, and by a fortunate accident was enabled to make use of the princesses' friendship to confer a slight favour on the great banker Paris-Duverney. Duverney testified his gratitude in a most substantial manner; he bestowed shares in several of his speculations upon Beaumarchais, and the latter, whose business talents

were of a high order, soon realized a handsome fortune. In 1764 he took a journey to Spain, partly with commercial objects in view, but principally on account of the Clavijo affair, which was afterwards made famous by the Goezman memoirs, and by Goethe's drama. Four years later he made his first essay on the stage with the sentimental drama *Eugénie*, which was followed after an interval of two years by *Les Deux Amis.* Neither had more than moderate success, and it was clear that, though the author might be unaware of it, his strength did not lie in the grave and sentimental. Meantime the clouds of the first great storm in Beaumarchais's life were gathering round him. He was very generally disliked as an upstart, and there were many ready to seize the first opportunity of hurling him from the position he had attained. Duverney, his great benefactor, died in 1770; but some time before his death a duplicate settlement of the affairs between him and Beaumarchais had been drawn up, in which the former acknowledged himself debtor to the latter for 16,000 francs. Duverney's heir, Count la Blache, a bitter enemy of Beaumarchais, denied the validity of this document, though without directly stigmatizing it as a forgery. The matter was put to trial. Beaumarchais gained his cause, but his adversary at once carried the case before the parliament, and in the early part of 1773 that body was preparing to give its decision on the report of one of its members, M. Goezman. Beaumarchais was well-nigh in despair; ruin stared him in the face; he was looked upon not only with dislike but with suspicion and contempt. Worst of all, he was unable to obtain an interview with Goezman, in whose hands his fate rested. At last, just before the day on which the report was to be given in, he was informed privately that, by presenting 200 louis to Mme. Goezman and 15 to her secretary, the desired interview might take place; if the result should prove unfavourable the money would be refunded. The money was sent and the interview obtained; but the decision was adverse, and 200 louis were returned, the 15 going as business expenses to the secretary. Beaumarchais, who had learned that there was no secretary save Mme. Goezman herself, insisted on restitution of the 15 louis, and the lady, in her passion, denied all knowledge of the affair. Her husband, who seems not to have been cognisant of the transaction at first, and who, doubtless, thought the defeated litigant would be easily put down, at once brought an accusation against him in parliament for an attempt to corrupt a judge. The battle was fought chiefly through the *Mémoires*, or reports published by the adverse parties, and in it Beaumarchais's success was most complete. All his best qualities were drawn forth by the struggle; his wit, energy, and cheerfulness seemed to be doubled; and for vivacity of style, fine satire, and broad humour, his famous *Mémoires* have never been surpassed. Even Voltaire was constrained to envy them. Nor was the effect of the struggle apparent only in Beaumarchais himself. He was attacking the parliament through one of its members, and the parliament was the universally detested body formed by the chancellor Maupeou. The *Mémoires* were, therefore, hailed with general delight; and the author, from being perhaps the most unpopular man in France, became at once the idol of the people. The decision in the case, however, so far as law went, was against him. The parliament condemned him *au blâme,—i.e.*, to civic degradation; but he obtained restitution of his rights within two years, and finally triumphed over his adversary La Blache.

During the next few years his employment was of a somewhat singular nature. He was engaged by the king in secret service, principally to destroy certain scurrilous pamphlets concerning Mme. du Barry, the publication of which had been threatened. His visits to England, on these missions, in which he was very successful, led him to take a deep interest in the impending struggle between the colonies and the mother country. His sympathies were entirely with the Americans; and by his unwearied exertions he succeeded in inducing the French Government to give ample, though private, assistance in money and arms to the insurgent colonists. He himself, partly on his own account, partly as an agent, carried on an enormous traffic with America. During the same period he had laid the foundations of a more enduring fame by his two famous comedies, the best of their class since those of Molière. The earlier, *Le Barbier de Seville*, after a short prohibition, was put on the stage in 1775. The first representation was a complete failure. Beaumarchais had overloaded the last scene with allusions to the facts of his own case and the whole action of the piece was laboured and heavy. But with undaunted energy he set to work, cut down and remodelled the piece in time for the second representation, when it achieved a complete success. The intrigues which were necessary in order to obtain a licence for the second and more famous comedy *Le Mariage de Figaro* are highly amusing, and throw much light on the unsettled state of public sentiment at the time. The play was completed in 1781, but the opposition of Louis XVI., who saw its dangerous tendencies, was not overcome till 1784. The comedy had an unprecedented success. The principal character in both plays, the world-famous *Figaro*, is a completely original conception; and for mingled wit, shrewdness, gaiety, and philosophic reflection, may not unjustly be ranked alongside of the great Tartuffe. To English readers the Figaro plays are generally known through the adaptations of them in the grand operas of Mozart and Rossini; but in France they long retained popularity as acting pieces. Beaumarchais's later productions, the bombastic opera *Tarare*, and the drama *The Guilty Mother*, which was very popular, are hardly worthy of his genius.

By his writings Beaumarchais contributed greatly, though quite unconsciously, to hurry on the events that led to the Revolution. At heart he hardly seems to have been a republican, and the new state of affairs did not benefit him. His popularity had been somewhat lessened by the affairs Bergasse and Mirabeau, and his great wealth and splendid mansion exposed him to the enmity of the envious. A speculation into which he entered, to supply the Convention with muskets from Holland, proved a ruinous failure. He was charged with treason to the Republic, and was obliged for some time to take refuge in Holland and England. His memoirs entitled, *Mes Six Époques*, detailing his sufferings under the Republic, are not unworthy of the Goezman period. His courage and happy disposition never deserted him; he was gay and hopeful up to the time of his death, which took place suddenly in May 1799.

Loménie, *Beaumarchais et son Temps*, 1856; Eng. trans. of the same by H. S. Edwards, 4 vols., 1856. Beaumarchais's works have been published by Gudin, 7 vols., 1809; and by Furne, 6 vols., 1827.

BEAUMARIS (formerly Bornovor, and deriving its present French name of Beau Marais from Edward I.), a borough and market-town of Anglesea, North Wales. It is situated on the Bay of Beaumaris, at the northern entrance of the Menai Straits, in lat. 53° 16′ N., long. 4° 5′ W. The town consists of several streets; and at the extremity of the principal one stands the castle. This fortress was built by Edward I. about 1295. It covers a great extent of ground, but its imposing effect is somewhat lessened by its low position, which was so designed that the fosse might communicate with the sea, so that vessels might unload beneath the walls. The chapel, dedicated to

the Virgin, is a spacious structure, containing several fine monuments. A free school was founded here in 1603. The principal buildings are the town-hall, county hall, prison, custom-house, assembly-room, and national school. Beaumaris has no manufactures and comparatively little trade, but is much frequented as a bathing-place. It unites with Holyhead, Amlwch, and Llangefni in returning a member to parliament. The bay affords good anchorage, having seven fathoms of water at the lowest ebb. Population in 1871, 2291.

BEAUMONT AND FLETCHER

THE critical memoir prefixed by Mr Dyce to the only good and scholar-like edition of Beaumont and Fletcher has summed up once for all, in fulness of perfect order, what little can now be known of their lives. It may suffice here to extract from this complete and careful record a few main facts and necessary dates, taking as little note as need be of any supplementary or hypothetical matters. Six or seven years before the death of his brother in art, John Fletcher was born in December 1579 at Rye in Sussex, and baptized on the 20th of the same month. Richard Fletcher, his father, afterwards queen's chaplain, dean of Peterborough, and bishop successively of Bristol, Worcester, and London, was then minister of the parish in which the son was born who was to make their name immortal. That son was just turned of seven when the dean distinguished and disgraced himself as the spiritual tormentor of the last moments on earth of Mary Stuart. When not quite twelve he was admitted pensioner of Bene't College, Cambridge, and two years later was made one of the Bible-clerks: of this college Bishop Fletcher had been president twenty years earlier, and six months before his son's admission had received from its authorities a first letter of thanks for various benefactions, to be followed next year by a second. Four years later than this, when John Fletcher wanted five or six months of his seventeenth year, the bishop died suddenly of over much tobacco and the displeasure of Queen Elizabeth at his second marriage,—this time, it appears, with a lady of such character as figures something too frequently on the stage of his illustrious son. He left eight children by his first marriage in such distress that their uncle, Dr Giles Fletcher, author of a treatise on the Russian commonwealth which is still held in some repute, was obliged to draw up a petition to the queen on their behalf, which was supported by the intercession of Essex, but with what result is uncertain. From this date we know nothing of the fortunes of John Fletcher, till the needy orphan boy of seventeen reappears as the brilliant and triumphant poet whose name is linked for all time with the yet more glorious name of Francis Beaumont, third and youngest son of Sir Francis Beaumont of Grace-Dieu, one of the justices of the Common Pleas,—born, according to general report, in 1586, but, according to more than one apparently irrefragable document, actually born at least a year earlier. The first record of his existence is the entry of his name, together with those of his elder brothers Henry and John, as a gentleman-commoner of Broadgates Hall, Oxford, now supplanted by Pembroke College. But most lovers of his fame will care rather to remember the admirable lines of Wordsworth on the "eager child" who played among the rocks and woodlands of Grace-Dieu; though it may be doubted whether even the boy's first verses were of the peaceful and pastoral character attributed to them by the great laureate of the lakes. That passionate and fiery genius which was so soon and for so short a time to "shake the buskined stage" with heroic and tragic notes of passion and of sorrow, of scorn and rage and slighted love and jealousy, must surely have sought vent from the first in fancies of a more ardent and ambitious kind; and it would be a likelier conjecture that when Frank Beaumont (as we know on more authorities than one that he was always called by his contemporaries, even in the full flush of his adult fame—"never more than Frank," says Heywood) went to college at the ripe age of twelve, he had already committed a tragedy or two in emulation of *Tamburlaine*, *Andronicus*, or *Jeronymo*. The date of his admission was 4th February 1597; on April 22d of the following year his father died; and on the 3d of November 1600, having left Oxford without taking his degree, the boy of fifteen was entered a member of the Inner Temple, his two brothers standing sponsors on the grave occasion. But the son of Judge Beaumont was no fitter for success at the bar than the son of Bishop Fletcher for distinction in the church: it is equally difficult to imagine either poet invested with either gown. Two years later appeared the poem of *Salmacis and Hermaphroditus*, a voluptuous and voluminous expansion of the Ovidian legend, not on the whole discreditable to a lad of seventeen, fresh from the popular love-poems of Marlowe and Shakespeare, which it naturally exceeds in long-winded and fantastic diffusion of episodes and conceits. At twenty-two Beaumont prefixed to the magnificent masterpiece of Ben Jonson some noticeable verses in honour of his "dear friend" the author; and in the same year (1607) appeared the anonymous comedy of *The Woman-Hater*, usually assigned to Fletcher alone; but being as it is in the main a crude and puerile imitation of Jonson's manner, and certainly more like a man's work at twenty-two than at twenty-eight, internal evidence would seem to justify, or at least to excuse, those critics who in the teeth of high authority and tradition would transfer from Fletcher to Beaumont the principal responsibility for this first play that can be traced to the hand of either. As Fletcher also prefixed to the first edition of *Volpone* a copy of commendatory verses, we may presume that their common admiration for a common friend was among the earliest and strongest influences which drew together the two great poets whose names were thenceforward to be for ever indivisible. During the dim eleven years between the death of his father and the dawn of his fame, we cannot but imagine that the career of Fletcher had been unprosperous as well as obscure. From seventeen to twenty-eight his youth may presumably have been spent in such painful struggles for success, if not for sustenance, as were never known to his younger colleague, who, as we have seen, was entered at Oxford a few months after Fletcher must in all likelihood have left Cambridge to try his luck in London; a venture most probably resolved on as soon as the youth had found his family reduced by the father's death to such ruinous straits that any smoother course can hardly have been open to him. Entering college at the same age as Fletcher had entered six years earlier, Beaumont had before him a brighter and briefer line of life than his elder. But whatever may have been their respective situations when, either by happy chance or, as Mr Dyce suggests, by the good offices of Jonson, they were first brought together, their intimacy soon became so much closer than that of ordinary brothers that the household which they shared as bachelors was conducted on such thoroughly communistic principles as might have satisfied the most trenchant theorist who ever proclaimed, as the cardinal point of his doctrine, a complete and absolute community of bed and board, with

all goods thereto appertaining. But in the year following that in which the two younger poets had united in homage to Jonson, they had entered into a partnership of more importance than this in "the same clothes and cloak, &c.," with other necessaries of life specified by Aubrey. In 1608, if we may trust the reckoning which seems trustworthiest, the twin stars of our stage rose visibly together for the first time. The loveliest, though not the loftiest, of tragic plays that we owe to the comrades or the successors of Shakespeare, *Philaster*, has always been regarded as the first-born issue of their common genius. The noble tragedy of *Thierry and Theodoret* has generally been dated earlier and assigned to Fletcher alone; but we can be sure neither of the early date nor the single authorship. The main body of the play, comprising both the great scenes which throw out into full and final relief the character of either heroine for perfect good or evil, bears throughout the unmistakable image and superscription of Fletcher; yet there are parts which for gravity and steady strength of style, for reserve and temperance of effect, would seem to suggest the collaboration of a calmer and more patient hand; and these more equable and less passionate parts of the poem recall rather the touch of Massinger than of Beaumont. In the second act, for example, the regular structure of the verse, the even scheme of the action, the exaggerated braggardism which makes of the hero a mere puppet or mouthpiece of his own self-will, are all qualities which, for better or for worse, remind us of the strength or the weakness of a poet with whom we know that Fletcher, before or after his alliance with Beaumont, did now and then work in common. Even the Arbaces of Beaumont, though somewhat too highly coloured, does not "write himself down an ass," like Thierry on his first entrance, after the too frequent fashion of Massinger's braggarts and tyrants; does not proclaim at starting or display with mere wantonness of exposure his more unlovely qualities in the naked nature of their deformity. Compare also the second with the first scene of the fourth act. In style and metre this second scene is as good an example of Massinger as the first is of Fletcher at his best. Observe especially in the elaborate narrative of the pretended self-immolation of Ordella these distinctive notes of the peculiar style of Massinger; the excess of parenthetic sentences, no less than five in a space of twenty lines; the classical common-place of allusion to Athens, Rome, and Sparta in one superfluous breath; the pure and vigorous but somewhat level and prosaic order of language, with the use of certain cheap and easy phrases familiar to Massinger as catchwords; the flat and feeble terminations by means of which the final syllable of one verse runs on into the next without more pause or rhythm than in a passage of prose; the general dignity and gravity of sustained and measured expression. These are the very points in which the style of Massinger differs from that of Fletcher; whose lightest and loosest verses do not overlap each other without sensible distinction between the end of one line and the beginning of the next; who is often too fluent and facile to be choice or forcible in his diction, but seldom if ever prosaic or conventional in phrase or allusion, and by no means habitually given to weave thoughts within thoughts, knit sentence into sentence, and hang whole paragraphs together by the help of loops and brackets. From these indications we might infer that this poem belongs altogether to a period later than the death of Beaumont; though even during his friend's life it appears that Fletcher was once at least allied with Massinger and two lesser dramatists in the composition of some play now unknown to men.

Hardly eight years of toil and triumph, of joyous and glorious life, were spared by destiny to the younger poet between the date assigned to the first radiant revelation of his genius in *Philaster* and the date which marks the end of all his labours. On the 6th of March 1616 Francis Beaumont died,—according to Jonson and tradition, "ere he was thirty years of age," but this we have seen to be inconsistent with the registry of his entrance at Oxford. If we may trust the elegiac evidence of friends, he died of his own genius and fiery overwork of brain; yet from the magnificent and masculine beauty of his portrait one should certainly never have guessed that any strain of spirit or stress of invention could have worn out so long before its time so fair and royal a temple for so bright and affluent a soul. A student of physiognomy will not fail to mark the points of likeness and of difference between the faces of the two friends; both models of noble manhood, handsome and significant in feature and expression alike;—Beaumont's the statelier and serener of the two, with clear thoughtful eyes, full arched brows, and strong aquiline nose, with a little cleft at the tip; a grave and beautiful mouth, with full and finely curved lips; the form of face a long pure oval, and the imperial head with its "fair large front" and clustering hair set firm and carried high with an aspect at once of quiet command and kingly observation: Fletcher's a more keen and fervid face, sharper in outline every way, with an air of bright ardour and glad fiery impatience; sanguine and nervous, suiting the complexion and colour of hair; the expression of the eager eyes and lips almost recalling that of a noble hound in act to break the leash it strains at;—two heads as lordly of feature and as expressive of aspect as any gallery of great men can show. That spring of 1616, we may note in passing, was the darkest that ever dawned upon England or the world; for, just forty-eight days afterwards, it witnessed, on the 23rd of April, the removal from earth of the mightiest genius that ever dwelt among men. Scarcely more than a month and a half divided the death-days of Beaumont and of Shakespeare. Some three years earlier by Mr Dyce's estimate, when about the age of twenty-eight, Beaumont had married Ursula, daughter and coheiress to Henry Isley of Sundridge in Kent, by whom he left two daughters, one of them posthumous. Fletcher survived his friend just nine years and five months; he died "in the great plague, 1625," and was buried on the 29th of August in St Saviour's, Southwark; not, as we might have wished, beside his younger fellow in fame, who but three days after his untimely death had added another deathless memory to the graves of our great men in Westminster Abbey, which he had sung in such noble verse. Dying when just four months short of forty-six, Fletcher had thus, as well as we can now calculate, altogether some fourteen years and six months more of life than the poet who divides with him the imperial inheritance of their common glory.

The perfect union in genius and in friendship which has made one name of the two names of these great twin brothers in song is a thing so admirable and so delightful to remember, that it would seem ungracious and unkindly to claim for either a precedence which we may be sure he would have been eager to disclaim. But if a distinction must be made between the Dioscuri of English poetry, we must admit that Beaumont was the twin of heavenlier birth. Only as Pollux was on one side a demigod of diviner blood than Castor can it be said that on any side Beaumont was a poet of higher and purer genius than Fletcher; but so much must be allowed by all who have eyes and ears to discern in the fabric of their common work a distinction without a difference. Few things are stranger than the avowal of so great and exquisite a critic as Coleridge, that he could trace no faintest line of demarcation between the plays which we owe mainly to Beaumont

and the plays which we owe solely to Fletcher. To others this line has always appeared in almost every case unmistakable. Were it as hard and broad as the line which marks off, for example, Shakespeare's part from Fletcher's in *The Two Noble Kinsmen*, the harmony would of course be lost which now informs every work of their common genius, and each play of their writing would be such another piece of magnificent patchwork as that last gigantic heir of Shakespeare's invention, the posthumous birth of his parting Muse which was suckled at the breast of Fletcher's as a child of godlike blood might be reared on the milk of a mortal mother—or in this case, we might sometimes be tempted to say, of a she-goat who left in the veins of the heaven-born suckling somewhat too much of his nurse Amalthæa. That question however belongs in any case more properly to the study of Shakespeare than to the present subject in hand. It may suffice here to observe that the contributions of Fletcher to the majestic temple of tragedy left incomplete by Shakespeare show the lesser workman almost equally at his best and at his worst, at his weakest and at his strongest. In the plays which we know by evidence surer than the most trustworthy tradition to be the common work of Beaumont and Fletcher, there is indeed no trace of such incongruous and incompatible admixture as leaves the greatest example of romantic tragedy—for *Cymbeline* and the *Winter's Tale*, though not guiltless of blood, are in their issues no more tragic than *Pericles* or the *Tempest*—an unique instance of glorious imperfection, a hybrid of heavenly and other than heavenly breed, disproportioned and divine. But throughout these noblest of the works inscribed generally with the names of both dramatists we trace on every other page the touch of a surer hand, we hear at every other turn the note of a deeper voice, than we can ever recognize in the work of Fletcher alone. Although the beloved friend of Jonson, and in the field of comedy his loving and studious disciple, yet in that tragic field where his freshest bays were gathered Beaumont was the worthiest and the closest follower of Shakespeare. In the external but essential matter of expression by rhythm and metre he approves himself always a student of Shakespeare's second manner, of the style in which the graver or tragic part of his historical or romantic plays is mostly written; doubtless, the most perfect model that can be studied by any poet who, like Beaumont, is great enough to be in no danger of sinking to the rank of a mere copyist, but while studious of the perfection set before him is yet conscious of his own personal and proper quality of genius, and enters the presence of the master not as a servant but as a son. The general style of his tragic or romantic verse is as simple and severe in its purity of note and regularity of outline as that of Fletcher's is by comparison lax, effusive, exuberant. The matchless fluency and rapidity with which the elder brother pours forth the stream of his smooth swift verse gave probably the first occasion for that foolish rumour which has not yet fallen duly silent, but still murmurs here and there its suggestion that the main office of Beaumont was to correct and contain within bounds the over-flowing invention of his colleague. The poet who while yet a youth had earned by his unaided mastery of hand such a crown as was bestowed by the noble love and the loving "envy" of Ben Jonson was, according to this tradition, a mere precocious pedagogue, fit only to revise and restrain the too liberal effusions of his elder in genius as in years. Now, in every one of the plays common to both, the real difficulty for a critic is not to trace the hand of Beaumont, but to detect the touch of Fletcher. Throughout the better part of every such play, and above all of their two masterpieces, *Philaster* and *The Maid's Tragedy*, it should be clear to the most sluggish or cursory of readers that he has not to do with the author of *Valentinian* and *The Double Marriage*. In those admirable tragedies the style is looser, more fluid, more feminine. From the first scene to the last we are swept as it were along the race of a running river, always at full flow of light and buoyant melody, with no dark reaches or perilous eddies, no stagnant pools or sterile sandbanks; its bright course only varied by sudden rapids or a stronger ripple here and there, but in rough places or smooth still stirred and sparkling with summer wind and sun. But in those tragic poems of which the dominant note is the note of Beaumont's genius a subtler chord of thought is sounded, a deeper key of emotion is touched, than ever was struck by Fletcher. The lighter genius is palpably subordinate to the stronger, and loyally submits itself to the impression of a loftier spirit. It is true that this distinction is never grave enough to produce a discord: it is also true that the plays in which the predominance of Beaumont's mind and style is generally perceptible make up altogether but a small section of the work that bears their names conjointly; but it is no less true that within this section the most precious part of that work is comprised. Outside it we shall find no figures so firmly drawn, no such clearness of outline, no such cunning of hands as we recognize in the three great studies of Bellario, Evadne, and Aspatia. In his male characters, as for instance in the parts of Philaster and Arbaces, Beaumont also is apt to show something of that exaggeration or inconsistency for which his colleague is perhaps more frequently and more heavily to blame; but in these there is not a jarring note, not a touch misplaced; unless, indeed, a rigid criticism may condemn as unfeminine and incongruous with the gentle beauty of her pathetic patience the device by which Aspatia procures herself the death desired at the hand of Amintor. This is noted as a fault by Mr Dyce; but may well be given for the sake of the magnificent scene which follows, and the highest tragic effect ever attained on the stage of either poet. That this as well as the greater part of those other scenes which are the glory of the poem is due to Beaumont might readily be shown at length by the process of comparison. The noble scene of regicide, which it was found expedient to cancel during the earlier years of the Restoration, may indeed be the work of Fletcher; but the part of Evadne must undoubtedly be in the main assigned to the more potent hand of his fellow. There is a fine harmony of character between her naked audacity in the second act and her fierce repentance in the fourth, which is not unworthy a disciple of the tragic school of Shakespeare; Fletcher is less observant of the due balance, less heedful of the nice proportions of good and evil in a faulty and fiery nature, compounded of perverse instinct and passionate reaction. From him we might have had a figure as admirable for vigour of handling, but hardly in such perfect keeping as this of Beaumont's Evadne, the murderess-Magdalen, whose penitence is of one crimson colour with her sin. Nor even in Fletcher's Ordella, worthy as the part is throughout even of the precious and exquisite praise of Lamb, is there any such cunning touch of tenderness or delicate perfume of pathos as in the parts of Bellario and Aspatia. These have in them a bitter sweetness, a subtle pungency of mortal sorrow and tears of divine delight, beyond the reach of Fletcher. His highest studies of female character have dignity, energy, devotion of the heroic type; but they never touch us to the quick, never waken in us any finer and more profound sense than that of applause and admiration. There is a modest pathos now and then in his pictures of feminine submission and slighted or outraged love; but this submission he is apt to make too servile, this love too dog-like in its abject devotion to retain that tender reverence which so many generations of readers have paid to the sweet memories of

Aspatia and Bellario. To excite compassion was enough for Fletcher, as in the masculine parts of his work it was enough for him to excite wonder, to sustain curiosity, to goad and stimulate by any vivid and violent means the interest of readers or spectators. The single instance of noble pathos, the one scene he has left us which appeals to the higher and purer kind of pity, is the death of the child of Hengo in *Bonduca*,—a scene which of itself would have sufficed to enrol his name for ever on the list of our great tragic poets. To him we may probably assign the whole merit of that fiery and high-toned tragedy, with all its spirit and splendour of national and martial passion; the conscious and demonstrative exchange of courtesy between Roman and Briton, which is one of the leading notes of the poem, has in it a touch of overstrained and artificial chivalry characteristic of Fletcher; yet the parts of Caratach and Pœnius may be counted among the loftiest and most equal of his creations. But no surer test or better example can be taken of the distinctive quality which denotes the graver genius of either poet than that supplied by a comparison of Beaumont's *Triumph of Love* with Fletcher's *Triumph of Death*. Each little play, in the brief course of its single act, gives proof of the peculiar touch and special trick of its author's hand: the deeper and more delicate passion of Beaumont, the rapid and ardent activity of Fletcher, have nowhere found a more noticeable vent for the expression respectively of the most tender and profound simplicity of quiet sweetness, the most buoyant and impatient energy of tragic emotion.

In the wider field of their comic or romantic drama it is yet easier to distinguish the respective work of either hand. The bias of Fletcher was towards mixed comedy; his lightest and wildest humour is usually crossed or tempered by an infusion of romance; like Shakespeare in this one point at least, he has left no single play without some touch on it of serious interest, of poetic eloquence or fancy, however slight and fugitive. Beaumont, evidently under the imperious influence of Ben Jonson's more rigid theories, seems rather to have bent his genius with the whole force of a resolute will into the form or mould prescribed for comedy by the elder and greater comic poet. The admirable study of the worthy citizen and his wife, who introduce to the stage and escort with their applause *The Knight of the Burning Pestle* through his adventurous career to its untimely end, has all the force and fulness of Jonson's humour at its best, with more of freshness and freedom. In pure comedy, varied with broad farce and mock heroic parody, Beaumont was the earliest as well as the ablest disciple of the master whose mantle was afterwards to be shared among the academic poets of a younger generation, the Randolphs and Cartwrights who sought shelter under the shadow of its voluminous folds. The best example of the school of Jonson to be found outside the ample range of his own work is *The Scornful Lady*, a comedy whose exceptional success and prolonged popularity must have been due rather to the broad effect of its forcible situations, its wealth and variety of ludicrous incidents, and the strong gross humour of its dialogue, than to any finer quality of style, invention, or character. It is the only work of Beaumont and Fletcher which a critic who weighs the meaning of his words can admit to be as coarse as the coarsest work of Ben Jonson. They are prone, indeed, to indulge elsewhere in a wanton and exuberant licence of talk; and Fletcher, at least, is liable to confuse the shades of right and wrong, to deface or efface the boundary lines of good and evil, to stain the ermine of virtue and palliate the nakedness of vice with the same indecorous and incongruous laxity of handling. Often, in mere haste to despatch the business of a play, to huddle up a catastrophe or throw out some particular scene into sharp and immediate relief, he will sacrifice all seemliness and consistency of character to the present aim of stage effect, and the instant impression of strong incident or audacious eloquence. His heroines are too apt to utter sentiments worthy of Diana in language unworthy of Doll Tearsheet. But in this play both style and sentiment are throughout on a lower level, the action and emotion are of a baser kind than usual; the precept of Aristotle and the practice of Jonson have been so carefully observed and exaggerated that it might almost be said to offer us in one or two places an imitation not merely of the sorrier but of the sorriest qualities of human nature; and full as it is of spontaneous power and humorous invention, the comedy extolled by the moral Steele (with just so much of reservation as permits him to deprecate the ridicule cast upon the clerical character) is certainly more offensive to artistic law and æsthetic judgment by the general and ingrained coarseness of its tone, than the tragi-comedy denounced by the immoral Dryden as exceeding in licence his own worst work and that of his fellow playwrights; an imputation, be it said in passing, as groundless as the protest pleaded on their behalf is impudent; for though we may hardly agree with the uncompromising panegyrist who commends that play in particular to the approval of "the austere scarlet" (remembering, perhaps, that Aristophanes was the chosen bedfellow of Chrysostom), there is at least no such offence against art or taste in the eccentricity of its situations or the daring of its dialogue. The buoyant and facile grace of Fletcher's style carries him lightly across quagmires in which a heavier-footed poet, or one of slower tread, would have stuck fast, and come forth bemired to the knees. To Beaumont his stars had given as birthright the gifts of tragic pathos and passion, of tender power, and broad strong humour; to Fletcher had been allotted a more fiery and fruitful force of invention, a more aerial ease and swiftness of action, a more various readiness and fulness of bright exuberant speech. The genius of Beaumont was deeper, sweeter, nobler than his elder's: the genius of Fletcher more brilliant, more supple, more prodigal, and more voluble than his friend's. Without a taint or a shadow on his fame of such imitative servility as marks and degrades the mere henchman or satellite of a stronger poet, Beaumont may fairly be said to hold of Shakespeare in his tragedy, in his comedy of Jonson; in each case rather as a kinsman than as a client, as an ally than as a follower: but the more special province of Fletcher was a land of his own discovering, where no later colonist has ever had power to settle or to share his reign. With the mixed or romantic comedy of Shakespeare it has nothing in common except the admixture or alternation of graver with lighter interest, of serious with humorous action. Nothing is here of his magic exaltation or charm of fairy empire. The rare and rash adventures of Fletcher on that forbidden track are too sure to end in pitiful and shameful failure. His crown of praise is to have created a wholly new and wholly delightful form of mixed comedy or dramatic romance, dealing merely with the humours and sentiments of men, their passions and their chances; to have woven of all these a web of emotion and event with such gay dexterity, to have blended his colours and combined his effects with such exquisite facility and swift light sureness of touch, that we may return once and again from those heights and depths of poetry to which access was forbidden him, ready as ever to enjoy as of old the fresh incomparable charm, the force and ease and grace of life, which fill and animate the radiant world of his romantic invention. Neither before him nor after do we find, in this his special field of fancy and of work, more than shadows or echoes of his coming or departing genius. Admirable as are his

tragedies already mentioned, rich in splendid eloquence and strong in large grasp of character as is the Roman history of *The False One*, full of interest and vigour as is the better part of *Rollo Duke of Normandy*, and sublime in the loveliness of passion as is the one scene of perfect beauty and terror which crowns this latter tragedy, Fletcher may claim a yet higher and more special station among his great dramatic peers by right of his comic and romantic than by right of his tragic and historic plays. Even in these he is more a romantic than a tragic poet. The quality of his genius, never sombre or subtle or profound, bears him always towards fresh air and sunshine. His natural work is in a midday world of fearless boyish laughter and hardly bitter tears. There is always more of rainbow than of storm in his skies; their darkest shadow is but a tragic twilight. What with him is the noon of night would seem as sunshine on the stage of Ford or Webster. There is but one passage in all these noble plays which lifts us beyond a sense of the stage, which raises our admiration out of speech into silence, tempers and transfigures our emotion with a touch of awe. And this we owe to the genius of Beaumont, exalted for an instant to the very tone and manner of Shakespeare's tragedy, when Amintor stands between the dead and the dying woman whom he has unwittingly slain with hand and tongue. The first few lines that drop from his stricken lips are probably the only verses of Beaumont or Fletcher which might pass for Shakespeare's even with a good judge of style—

"This earth of mine doth tremble," &c.

But in Fletcher's tragedy, however we may be thrilled and kindled with high contagious excitement, we are never awed into dumb delight or dread, never pierced with any sense of terror or pity too deep or even deep enough for tears. Even his Brunhalts and Martias can hardly persuade us to forget for the moment that "they do but jest, poison in jest." A critic bitten with the love of classification might divide those plays of Fletcher usually ranked together as comedies into three kinds: the first he would class under the head of pure comedy, the next of heroic or romantic drama, the third of mixed comedy and romance; in this, the last and most delightful division of the poet's work the special qualities of the two former kinds being equally blended and delicately harmonized. The most perfect and triumphant examples of this class are *The Spanish Curate*, *Monsieur Thomas*, *The Custom of the Country*, and *The Elder Brother*. Next to these, and not too far below them, we may put *The Little French Lawyer* (a play which in its broad conception of a single eccentric humour suggests the collaboration of Beaumont and the influence of Jonson, but in style and execution throughout is perfect Fletcher), *The Humorous Lieutenant* (on which an almost identical verdict might be passed), *Women Pleased*, *Beggars' Bush*, and perhaps we might add *The Fair Maid of the Inn;* in most if not in all of which the balance of exultant and living humour with serious poetic interest of a noble and various kind is held with even hand and the skill of a natural master. In pure comedy *Rule a Wife and Have a Wife* is the acknowledged and consummate masterpiece of Fletcher. Next to it we might class, for comic spirit and force of character, *Wit without Money*, *The Wildgoose Chase*, *The Chances*, and *The Noble Gentleman*,—a broad poetic farce to whose overflowing fun and masterdom of extravagance no critic has ever done justice but Leigh Hunt, who has ventured, not without reason, to match its joyous and preposterous audacities of superlative and sovereign foolery with the more sharp-edged satire and practical merriment of *King and no King*, where the keen prosaic humour of Bessus and his swordsmen is as typical of the comic style in which Beaumont had been trained up under Ben Jonson as the high interest and graduated action of the serious part of the play are characteristic of his more earnest genius. Among the purely romantic plays of Fletcher, or those in which the comic effect is throughout subordinate to the romantic, *The Knight of Malta* seems most worthy of the highest place for the noble beauty and exaltation of spirit which informs it with a lofty life, for its chivalrous union of heroic passion and Catholic devotion. This poem is the fairest and the first example of those sweet fantastic paintings in rose-colour and azure of visionary chivalry and ideal holiness, by dint of which the romance of more recent days has sought to cast the glamour of a mirage over the darkest and deadliest "ages of faith." The pure and fervent eloquence of the style is in perfect keeping with the high romantic interest of character and story. In the same class we may rank among the best samples of Fletcher's workmanship *The Pilgrim*, *The Loyal Subject*, *A Wife for a Month*, *Love's Pilgrimage*, and *The Lover's Progress*,—rich all of them in exquisite writing, in varied incident, in brilliant effects and graceful or passionate interludes. In *The Coxcomb* and *The Honest Man's Fortune*—two plays which, on the whole, can hardly be counted among the best of their class—there are tones of homelier emotion, touches of a simpler and more pathetic interest than usual; and here, as in the two admirable first scenes between Leucippus and Bacha, which relieve and redeem from contempt the tragic burlesque of *Cupid's Revenge*, the note of Beaumont's manner is at once discernible.

Even the most rapid revision of the work done by these great twin poets must impress every capable student with a sense of the homage due to this living witness of their large and liberal genius. The loss of their names from the roll of English poetry would be only less than the loss of the few greatest inscribed on it. Nothing could supply the want of their tragic, their comic or romantic drama; no larger or more fiery planet can ever arise to supplant or to eclipse the twin lights of our zodiac. Whatever their faults of shortcoming or excess, there is in their very names or the mere thought of their common work a kind of special and personal attraction for all true lovers of high dramatic poetry. There is the glory and grace of youth in all they have left us; if there be also somewhat too much of its graceless as well as its gracious qualities, yet there hangs about their memory as it were a music of the morning, a breath and savour of bright early manhood, a joyous and vigorous air of free life and fruitful labour, which might charm asleep for ever all thought or blame of all mortal infirmity or folly, or any stain of earth that may have soiled in passing the feet of creatures half human and half divine while yet they dwelt among men. For good or for evil, they are above all things poets of youth; we cannot conceive of them grown grey in the dignity of years, venerable with the authority of long life, and weighted with the wisdom of experience. In the Olympian circle of the gods and giants of our race who on earth were their contemporaries and corrivals, they seem to move among the graver presences and figures of sedater fame like the two spoilt boys of heaven, lightest of foot and heart and head of all the brood of deity. Shakespeare may have smiled as Jonson may have nodded approval of their bright swift work, neither of these great elders grudging his praise to the special charm which won for it a preference during one generation at least even over their own loftier and weightier verse; and indeed the advance in natural ease, in truth and grace of dialogue, is alike manifest whether we turn to such of their comic characters as Valentine and Don John, Rutilio and Monsieur Thomas, from the Truewit of Jonson or even from the Mercutio of Shakespeare; the one too stiff with classic starch, the

other too full of mere verbal catches and forced conceits, to persuade us that either can in any age have fairly represented the light free talk and facile humour of its youth. In another field than this Beaumont and Fletcher hold as high and secure a station of their own as any poet of their race. In perfect workmanship of lyrical jewellery, in perfect bloom and flower of song-writing, they equal all compeers whom they do not excel; the blossoms of their growth in this kind may be matched for colour and fragrance against Shakespeare's, and for morning freshness and natural purity of form exceed the finest grafts of Jonson. *The Faithful Shepherdess* alone might speak for Fletcher on this score, being as it is simply a lyric poem in semi-dramatic shape, to be judged only as such, and as such almost faultless; but in no wise to be classed for praise or blame among the acting plays of its author, whose one serious error in the matter was the submission of his Dryad to the critical verdict of an audience too probably in great part composed of clowns and satyrs far unlike the loving and sweet tongued sylvan of his lovely fancy. And whether we assign to him or to Beaumont the divine song of melancholy (*mæstius lacrymis Simonideis*), perfect in form as Catullus and profound in sentiment as Shelley, which Milton himself could but echo and expand, could not heighten or deepen its exquisite intensity of thought and world alike, there will remain witness enough for the younger brother of a lyric power as pure and rare as his elder's.

The excess of influence and popularity over that of other poets usually ascribed to the work of Beaumont and Fletcher for some half century or so after their own time has perhaps been someweat overstated by tradition. Whatever may have been for a season the fashion of the stage, it is certain that Shakespeare can show two editions for one against them in folio; four in all from 1623 to 1685, while they have but their two of 1647 and 1679. Nor does one see how it can accurately or even plausibly be said that they were in any exact sense the founders of a school either in comedy or in tragedy. Massinger, for some years their survivor, and in some points akin to them as a workman, cannot properly be counted as their disciple; and no leading poet of the time had so much in common with them as he. At first sight, indeed, his choice of romantic subject and treatment of foreign stores, gathered from the fertile tale-tellers of the south, and ranging in date from Boccaccio to Cervantes, may seem to mark him out as a member of the same school; but the deepest and most distinctive qualities of his genius set it far apart from theirs; though undoubtedly not so far that any discrepancy or discord should impair the excellence or injure the keeping of works in which he took part with Fletcher. Yet, placed beside theirs, the tone of his thought and speech seems by comparison severe as well as sober, and sad as well as severe. Their extravagant and boyish insanity of prostrate royalism is not more alien from his half pensive and half angry undertone of political protest than his usually careful and complete structure of story from their frequently lax and slovenly incoherence of character or plot, than his well composed and proportioned metre from their lighter and looser melodies, than the bitter insistence and elaborate acrimony of his judicial satire on hypocrisy or oppression from the gaiety or facility of mood which suffers them in the shifting of a scene to redeem their worst characters by some juggler's trick of conversion at the last moment allowed them to wind up a play with universal reconciliation and an act of oblivion on all hands. They could hardly have drawn with such steady skill and explicit finish an Overreach or a Luke; but the strenuous and able work of Massinger at its highest point of success has no breath in it of their brighter and more immediate inspiration. Shirley, on the other hand, may certainly be classed as a pupil who copied their style in water-colour; his best tragedy and his best comedy, *The Traitor* and *The Lady of Pleasure*, might pass muster undetected among the plays of Fletcher, and might fairly claim to take rank above the lowest class of these. In the finest work of Middleton we recognize an almost exact reproduction of Fletcher's metrical effects,—a reverberation of that flowing music, a reiteration of those feminine final notes. In his later tragi-comedies, throughout his masterpiece of *Women beware Women*, and in the noble scenes which make up the tragic or serious parts of *The Changeling* or *The Spanish Gipsy*,—wherever, in a word, we find the admirable but unequal genius of this poet at its best—we find a likeness wholly wanting in his earlier and ruder work, which undoubtedly suggests the influence of Fletcher. Other instances of imitation, other examples of discipleship, might perhaps be found among lesser men of the next generation; but the mass of succeeding playwrights began in a very short time to lower the style and debase the scheme of dramatic poetry; and especially to loosen the last ties of harmony, to deface the very form and feature of tragic verse. In Shirley, the last and least of those in whom the lineal blood of the old masters was yet discernible, we find side by side with the fine ancestral indications of legitimate descent exactly such marks of decadence rather than degeneracy as we might have anticipated in the latest heir of a long line which began with the rise of Marlowe, " sun of the morning," in the highest heaven of our song, to prepare a pathway for the sun. After Shakespeare there was yet room for Beaumont and Fletcher; but after these and the other constellations had set, whose lights filled up the measure of that diviner zodiac through which he moved, there was but room in heaven for the pallid moonrise of Shirley; and before this last reflex from a sunken sun was itself eclipsed, the glory had passed away from our drama, to alight upon that summit of epic song whence Milton held communion with darkness and the stars. (A. C. S.)

BEAUNE, the chief town of an arrondissement in France, in the department of Côte d'Or, situated on the River Bourzeoise, twenty-three miles S.S.W. of Dijon, on the railway from Paris to Lyons. The town is of poor appearance, but has several buildings of interest, such as the churches of Nôtre Dame and Saint Pierre, both of the 12th century, the hospital, founded by Nicholas Rollin in 1443, and the belfry of the old town-house. Of more modern erection are the public baths, the theatre, the communal college, and the library. In the 18th century there were no fewer than seven monastic buildings in the town besides a Bernardine abbey, a Carthusian convent, and a society of priests engaged in educational pursuits. Beaune enjoys considerable commercial prosperity as the principal seat of the Burgundian wine-trade; it also manufactures cloth, cutlery, and leather, and has dye-works, flour-mills, and distilleries. Population in 1871, 10,415.

Beaune appears as a fortified place as early as the 7th century, and for some time was the capital of a separate duchy. United to Burgundy in 1227, it became the first seat of the Burgundy parliament, or *Jours Généraux*, and was the residence of several of the dukes. On the death of Charles the Bold, it sided with his daughter, but was besieged and taken by Louis XI. in 1478. It suffered severely in the wars of the League, prospered in the reign of Henry IV., and was greatly injured by the revocation of the Edict of Nantes

BEAUSOBRE, ISAAC DE, a learned Protestant writer, of French origin, was born at Niort in 1659, and after studying theology at the Protestant Academy of Saumur, was ordained at the age of twenty-two. He was forced into Holland to avoid the execution of a sentence condemning him to make the *amende honorable* for having broken the royal signet, which was put upon the door of a church of the reformers to prevent the public profession of their religion. He went to Berlin in 1694, and was made chaplain to the king of Prussia, and counsellor of the royal consistory. He died in 1738, aged seventy-nine, after having published several works, among which may be mentioned—(1.) *Défense de la Doctrine des Réformés, sur la Providence, sur la Prédestination, sur la Grâce, et sur l'Eucharistie* (Magdeburg, 1694–8); (2.) A translation of the New Testament, with Notes, jointly with M. Lenfant (1718), much esteemed among Protestants; (3.) *Dissertation sur les Adamites de Bohéme*, a curious work; (4.) *Histoire Critique de Manichée et du Manichéisme*, 2 tom. 4to (Amst., 1734–9), a very learned and valuable work, discussing, as Gibbon observes, "many deep questions of Pagan and Christian theology, and forming a rich treasury of facts and opinions;" (5.) Several dissertations in the *Bibliothèque Britannique*. Beausobre had strong sense with profound erudition, and was one of the best writers of his time, and he preached as he wrote, with spirit and ability.

BEAUVAIS, a town of France, capital of an arrondissement in the department of Oise, situated in 49° 26′ N. lat. and 2° 14′ E. long., about 45 miles N. of Paris, in a valley at the junction of the Avelon and the Therain. The town is irregularly built, but possesses several edifices of historical and architectural interest. Chief among these is the cathedral of Saint Pierre, begun in 1225, continued at intervals till the 16th century by various ambitious projectors, and still incomplete. Its stained glass windows are both ancient and beautiful, though they are rivalled by those of Saint Étienne, another of the older churches in the town. Contiguous to the cathedral is a *basilica* of the 6th century, one of the oldest buildings of the kind in France. The episcopal palace, now used as a court-house, was built in the 16th century. Among the secular buildings are the town-house, dating from 1754, the college, which was formerly an Ursuline convent, a library with upwards of 15,000 volumes, a natural history museum, a theatre, a hospital, and barracks. The industry of Beauvais comprises, besides the weaving of tapestry, which dates from 1664, the manufacture of velvet and various kinds of cotton and woollen goods, leather, and earthenware. An extensive trade is carried on in grain and wine, and the products of the industrial establishments. Beauvais was known to the Romans as *Cæsaromagus*, and took its present name from the Gallic tribe of the *Bellovaci*, whose capital it was. In the 9th century it was erected into a countship, which about 1013 passed to the bishops of Beauvais, who ultimately became peers of France. In 1346 the town had to defend itself against the English, who again besieged it in 1433. The siege which it suffered in 1472 at the hands of the Duke of Burgundy was rendered famous by the heroism of the women, under the leadership of Jeanne Hachette, whose memory is still celebrated by a procession on the 14th of October (the feast of Ste Angadrême), in which the women take precedence of the men. Population in 1871, 15,542.

BEAVER, the English name of a genus of Mammals belonging to the order *Rodentia*, the two known species of which are among the largest members of that group. Both beavers, European and American, measure about 2 feet in length, exclusive of the tail, which is about 10 inches long, and are covered with the fur to which they owe their chief commercial value. This consists of two kinds of hair,—the one close-set, silky, and of a greyish colour; the other much coarser and longer, and of a reddish brown. Beavers are essentially aquatic in their habits, never travelling by land unless driven to it by necessity. Their hind feet are webbed to the nails, and in swimming those only are used, the front legs remaining motionless by the side. They differ from all other rodents in possessing a broad horizontally flattened tail, somewhat oval in form and covered with scales, which they use as an aid to their progress through the water, and not as a trowel for plastering their mud houses as was formerly supposed. The front incisor teeth in each jaw have a sharp chisel-like edge, and are so formed as to preserve this through life. They consist of an outer layer of orange-coloured enamel, and a broad inner layer of a softer substance. As the creature gnaws, the softer material is worn away more rapidly than the enamel, which thus protrudes in a sharp ridge. There is a continuous growth at the roots of those teeth to repair the constant waste that goes on at the cutting edge, so that should one of the incisors be destroyed, the opposite tooth, meeting with no check to its enlargement, will grow to an enormous length; and beavers have been found in which this abnormal growth had proved fatal by preventing the other teeth from coming together. The enamel is exceedingly hard; and, until superseded by English files, those teeth, fixed in wooden handles, were used by the North American Indians in carving their weapons of bone. The question whether the American and European beavers are the same or different species, has given rise to some controversy; but it is now generally conceded, chiefly on anatomical grounds, that they are distinct, although in outward appearance they are almost identical.

The European Beaver (*Castor fiber*) was at one time an inhabitant of the British Isles, having been found, according to Pennant, in certain Welsh rivers as late as the 12th century, while fossil remains of it occur in various parts of the country. In Scandinavia beavers are now extinct,—the last known specimen having been killed in 1844. Isolated pairs are still occasionally met with on the banks of the Rhone, the Weser, and the Elbe; and a considerable number are to be found in one of the parks belonging to the emperor of Austria, on the banks of the Danube, where they are strictly preserved. They also occur, though sparingly, in Russia and Poland, in the streams of the Ural Mountains, and in those which flow into the Caspian Sea. They are said to live in burrows on the banks of rivers, like the common water rat, and to show little of the architectural instinct so conspicuous in the American species; this, however, is probably more owing to unfavourable external conditions than to want of the faculty, for there is at least one well-authenticated instance of a colony of beavers, on a small stream near Magdeburg, whose habitations and dam were exactly similar to those found in America.

The American Beaver (*Castor canadensis*) extends over that part of the American continent included between the Arctic circle and the tropic of Cancer; owing, however, to the gradual spread of population over part of this area, and still more to the enormous quantity of skins that, towards the end of last century and the beginning of the present, were exported to Europe, numbering about 200,000 annually, this species was in imminent danger of extirpation. More recently the employment of silk and of the fur of the South American Coypu in the manufacture of hats so lessened the demand for beaver skins that the trapping of these animals became unprofitable; and being thus little sought after for many years, they have again become abundant in such of their old haunts as have not yet been occupied by man, so that the trade in beaver

skins has now nearly attained its former proportions. Solitary beavers, always males, and known as "old bachelors," or idlers, are found inhabiting burrows similar to those seen in Europe. These are generally found in the neighbourhood of new townships, and are supposed to be individuals that have remained after the colony had broken up, or that from some cause or another have been expelled from the society of their fellows. The American Beaver, however, is essentially social, inhabiting lakes, ponds, and rivers, as well as those narrow creeks which connect the lakes together. They generally, however, prefer flowing waters, probably on account of the advantages afforded by the current for transporting the materials of their dwellings. They also prefer deepish water, no doubt because it yields a better protection from the frost. When they build in small creeks or rivers, the waters of which are liable to dry or to be drained off, instinct leads them to the formation of dams. These differ in shape according to the nature of particular localities. Where the water has little motion the dam is almost straight; where the current is considerable it is curved, with its convexity towards the stream. The materials made use of are drift wood, green willows, birch, and poplars; also mud and stones intermixed in such a manner as must evidently contribute to the strength of the dam; but there is no particular method observed, except that the work is carried on with a regular sweep, and that all the parts are made of equal strength. "In places," says Hearne, "which have been long frequented by beavers undisturbed, their dams, by frequent repairing, become a solid bank, capable of resisting a great force both of ice and water; and as the willow, poplar, and birch generally take root and shoot up, they by degrees form a kind of regular planted hedge, which I have seen in some places so tall that birds have built their nests among the branches." Their houses are formed of the same materials as the dams, with little order or regularity of structure, and seldom contain more than four old, and six or eight young beavers. It not unfrequently happens that some of the larger houses have one or more partitions, but these are only posts of the main building left by the sagacity of the builders to support the roof, for the apartments, as some call them, have usually no communication with each other except by water. The beavers carry the mud and stones with their fore-paws, and the timber between their teeth. They always work in the night, and with great expedition. They cover their houses late every autumn with fresh mud, which, freezing when the frost sets in, becomes almost as hard as stone, and thus neither wolves nor wolverines can disturb their well-earned repose.

The favourite food of the American Beaver is the plant called *Nuphar luteum*, which bears a resemblance to a cabbage stalk, and grows at the bottom of lakes and rivers. They also gnaw the bark of birch, poplar, and willow trees. But during the bright summer days which clothe even the far northern regions with a luxuriant vegetation, a more varied herbage, with the addition of berries, is consumed. When the ice breaks up in spring they always leave their embankments, and rove about until a little before the fall of the leaf, when they return again to their old habitations, and lay in their winter stock of wood. They seldom begin to repair the houses till the frost sets in, and never finish the outer coating till the cold becomes pretty severe. When they erect a new habitation they fell the wood early in summer, but seldom begin building till towards the end of August.

The flesh of the American Beaver is usually eaten by the Indians and the Canadian voyageurs; and when roasted in the skin it is esteemed a delicacy. It is said to taste like pork. The *castoreum* of the beaver is a substance contained in two pyriform sacs, situated near the organs of reproduction, of a bitter taste, and slightly fœtid odour, at one time largely employed as a medicine for derangement of the nervous system, as hysteria, &c., but now little used. Fossil remains of both beavers are found in the Tertiary beds of the continents still inhabited by them, accompanied in each case by remains of an extinct species. The latter appear from their remains to have been much larger than those now existing.

BECCAFUMI, DOMENICO, was a distinguished painter of the school of Siena at the beginning of the 16th century. In the early days of the Tuscan republics Siena had been in artistic genius, and almost in political importance, the rival of Florence. But after the great plague in 1348 the city declined; and though her population always comprised an immense number of skilled artists and artificers, yet her school did not share in the general progress of Italy in the 15th century. About the year 1500, indeed, Siena had no native artists of the first importance; and her public and private commissions were often given to natives of other cities. But after the uncovering of the works of Raphael and Michel Angelo at Rome in 1508, all the schools of Italy were stirred with the desire of imitating them. Among those accomplished men who now, without the mind and inspiration of Raphael or Michel Angelo, mastered a great deal of their manner, and initiated the decadence of Italian art, several of the most accomplished arose in the school of Siena. (See articles PERUZZI and SODDOMA.) Among these was Domenico, born about 1488, of a peasant, one Giacomo di Pace, who worked on the estate of a well-to-do citizen named Lorenzo Beccafumi. Seeing some signs of a talent for drawing in his labourer's son, Lorenzo Beccafumi took the boy into his service and presently adopted him, causing him to learn painting from masters of the city. Known afterwards as Domenico Beccafumi, or by the nickname of Mecarino, signifying the littleness of his stature, the peasant's son soon gave proof of extraordinary industry and talent. In 1509 he went to Rome and steeped himself in the manner of the great men who had just done their first work in the Vatican. Returning to his native town, Beccafumi quickly gained employment and a reputation second only, if second, to Soddoma. He painted a vast number both of religious pieces for churches and of mythological decorations for private patrons, many of which are still to be seen where they were executed. But the work by which he will longest be remembered is that which he did for the celebrated pavement of the cathedral of Siena. For a hundred and fifty years the best artists of the state had been engaged laying down this pavement with vast designs in *commesso* work,—white marble, that is, engraved with the outlines of the subject in black, and having borders inlaid with rich patterns in many colours. From the year 1517 to 1544 Beccafumi was engaged in continuing this pavement. He made very ingenious improvements in the technical processes employed, and laid down multitudinous scenes from the stories of Ahab and Elijah, of Melchisedec, of Abraham, and of Moses. These are not so interesting as the simpler work of the earlier schools, but are much more celebrated and more jealously guarded. Such was their fame that the agents of Charles I. of England, at the time when he was collecting for Whitehall, went to Siena expressly to try and purchase the original cartoons. But their owner would not part with them, and they are now the property of the cathedral works. The subjects have been engraved on wood, by the hand, as it seems, of Beccafumi himself, who at one time or another essayed almost every branch of fine art. He made a triumphal arch and an immense mechanical horse for the procession of Charles V. on his entry into Siena. In his later days, being a solitary liver and con-

tinually at work, he is said to have accelerated his death by over-exertion upon the processes of bronze-casting. He died in 1551. (Vasari, ed. Lemonnier, x. 176–197; Ugurgieri, *Pompe Sanese;* G. Milanesi, *Documenti*, &c.)

BECCARIA, CESAR BONESANA, MARQUIS, a celebrated writer on the principles of jurisprudence and national economy, was born at Milan in the year 1735. He was educated in the Jesuit College at Parma, and showed at first a great fondness and aptitude for mathematics. The study of Montesquieu seems to have directed his attention towards economical questions; and his first publication (in 1762) was a tract on the derangement of the currency in the Milanese states, with a proposal for its remedy. Shortly after, in conjunction with his friends the Verris, he formed a literary society, and began to publish a small journal, in imitation of the *Spectator*, called *Il Caffè*. In 1764 Beccaria published his brief but justly celebrated treatise *Dei Delitti e delle Pene* ("On Crimes and Punishments"). The weighty reasonings of this work were expounded with all the additional force of a clear and animated style. It pointed out distinctly and temperately the grounds of the right of punishment, and from these principles deduced certain propositions as to the nature and amount of punishment which should be inflicted for any crime. The book had a surprising success. Within eighteen months it passed through six editions. It was translated into French by Morellet in 1766, and published with an anonymous commentary by Voltaire. An English translation appeared in 1768, and other countries followed the example. Many of the reforms in the penal codes of the principal European nations are traceable to Beccaria's treatise. In November 1768 the marquis was appointed to the chair of public law and economy, which had been founded expressly for him at the Palatine College of Milan. His lectures on political economy, which are based on strict utilitarian principles, are in marked accordance with the theories of the English school of economists. They are published in the collection of Italian writers on political economy (*Scrittori Classici Italiani*, vols. xi. and xii.) In 1771 Beccaria was made a member of the supreme economic council; and in 1791 he was appointed one of the board for the reform of the judicial code. In this post his labours were of very great value. He died in 1793. A notice of his life will be found prefixed to his lectures, referred to above.

BECCARIA, GIOVANNI BATTISTA, a distinguished electrician and practical astronomer, was born at Mondovi on the 2d of October 1716, and entered the religious order of the Pious Schools in 1732. He became professor of experimental physics, first at Palermo and then at Rome, and was appointed to a similar situation at Turin in 1748. He was afterwards made tutor to the young princes de Chablais and de Carignan, and continued to reside principally at Turin during the remainder of his life. In May 1755 he was elected a fellow of the Royal Society of London, to which he afterwards communicated several papers relating to his favourite pursuits. He died on the 27th of May 1781. Beccaria's name is associated with no great discovery in physical science; but he did much, both in the way of experiment and exposition, to spread abroad the researches of Franklin and others in the science of electricity. His own experiments, which were skilfully conducted, demonstrated a number of curious facts bearing on the relations of electricity to meteorological phenomena, to chemical action, and to some other points which have been since more thoroughly investigated. His principal work was the treatise *Dell' Elettricismo Artificiale e Naturale*, 1753, which was translated into English in 1776. He also contributed a number of papers to the *Philosophical Transactions*. In 1759 he was commissioned to measure an arc of the meridian in the neighbourhood of Turin. The result, which he published in the *Gradus Taurinensis*, 1774, is not now considered perfectly correct.

BECCLES, a market-town and municipal borough, in the county of Suffolk, on the right bank of the River Waveney, 32 miles N.N.E. of Ipswich. It consists of several streets, is well built, and contains a fine old parish church, enlarged and repaired in 1859, several dissenting chapels, a free school, founded in the reign of James I. a free grammar school, a handsome town-hall, a custom-house, and a corn exchange. Malting is carried on to some extent; and by means of the river, which is navigable from Yarmouth, a considerable trade in coals and produce is carried on. The incorporation of the town dates from 1584. Population in 1871, 4844.

BECERRA, GASPAR, a distinguished Spanish painter and sculptor, was born at Balza in 1520. He studied at Rome, it is said under Michel Angelo, and assisted Vasari in painting the hall of the Concelleria. He also contributed to the celebrated anatomical plates of Valverde. After his return to Spain he was extensively employed by Philip II., and decorated many of the rooms in the palace at Madrid with frescoes. He also painted altar pieces for several of the churches, most of which have been destroyed. His fame as a sculptor almost surpassed that as a painter. His best work was a magnificent figure of the Virgin, which was destroyed during the French war. Becerra died in 1570. The most competent judges assign to him the chief share in the establishment of the fine arts in Spain.

BÊCHE-DE-MER, or TREPANG, an important food luxury among the Chinese, Japanese, and other Eastern peoples, connected with the production of which a very considerable commerce exists in the Eastern Archipelago, the coasts of New Guinea, and generally on the coral reefs of the Pacific. It consists of several species of echinoderms, generally referred to the genus *Holothuria;* but very many varieties, widely distributed in Eastern seas, are prepared and sold in Chinese and Japanese markets. The creatures, which exist on coral reefs, have bodies from 6 to 15 inches long, shaped like a cucumber, hence a name they receive,—sea cucumbers. The skin is sometimes covered with spicules or prickles, and sometimes quite smooth, and with or without "teats" or ambulacral feet disposed in rows. Five varieties are recognized in the commerce of the Pacific Islands, the finest of which is the "brown with teats," which are worth, at the place of their preparation, £30 per ton. The large black, which come next in value, bring £25 per ton; the small black £20, red bellied £15, and white £12. The finest of these sell for as much as £100 per ton in China, where they are used in the gelatinous soups, which form an important article of food in that empire. The preparation of the creatures when caught is very simple. They are boiled for about twenty minutes, after which they are split up and gutted, when they are ready for drying. The drying is conducted in large sheds on hurdles placed above a brisk fire. The dried Bêches-de-mer being very hygrometric, it is necessary that they be immediately packed up and shipped on the conclusion of the drying process; and unless they are thoroughly dry decomposition sets in rapidly and destroys the entire cargo.

BECHER, JOHANN JOACHIM, a celebrated chemist, born at Spire in 1635. His father, a Lutheran clergyman, died while he was very young, and the boy was compelled to support himself by teaching. He was a diligent student, and acquired a very extensive acquaintance with chemistry and allied sciences. In 1666, after having travelled through some parts of Europe, he was made professor of medicine at Mentz. He then removed to Munich, where he superintended the magnificent laboratory. His somewhat turbulent and unbending disposition obliged him to leave Bavaria, and he proceeded to Vienna, where he gained

the friendship of Zinzendorf. He was made member of the council of commerce, and proposed various commercial schemes to the Austrian Government. He soon quarrelled with Zinzendorf; and about 1678 we find him at Haarlem. After a short time he visited England and Scotland, inspecting their mines. He died in 1682, it is said at London. He wrote many works, the principal of which are—(1), *Physica Subterranea*, which was printed at Leipsic in 1703 and 1739, in 8vo, with a small treatise by E. Stahl, entitled *Specimen Becherianum*; (2), *Experimentum chymicum novum*, 8vo; (3), *Character pro Notitia Linguarum universali*; (4), *Institutiones Chymicæ, seu Manuductio ad Philosophiam Hermeticam*, 4to; (5), *Institutiones Chymicæ, seu Œdipus Chemicus*, 12mo; (6), *Experimentum novum ac curiosum de Miniaria arenaria perpetua*, &c. In some respects he anticipated Stahl, whose phlogistic theory is an extension of what he says. He was also the discoverer of boracic acid.

BECHWANA, or BETJUANA, the name of a nation extending over a large tract of the interior of South Africa, lying between 22° and 28° S. lat. and 22° and 29° E. long. There are remains as well as traditions indicating that they once occupied lands further to the south and north of their present boundaries. The country is bounded on the W. by what may be called the southern Sahara; on the E. by the Limpopo, and on the N. by the Matebele, a tribe which escaped the power of the Chaka, the bloody chief of the Zulus. The country, though hilly and undulating, abounds in grassy plains and considerable forests of acacia. Trees, however, are scarce, as the grass is generally burned off every year; and the young wood is thus not allowed time to grow. The natives also, in order to get fresh garden ground and obtain branches to raise their houses and make fences, are constantly destroying trees, and thus increasing the dryness and sterility of the country. It is evident, from the dry beds of what were once rivers and from remains of ancient forests, that, at an early period, the country must have been abundantly watered. From the many cattle folds and walls of defence scattered over the country, and ruins of ancient towns, it is also evident that at that period stone-dykes were very common.

The number of the Bechwana has been variously estimated, and according to some amounts to more than 200,000. Their language is copious, with but few slight dialectic differences, being entirely free of the Hottentot elements found in the Kaffre and Zulu. The power of the language which, like the Kaffre and Zulu, belongs to the Ba-nta family, formerly unwritten, may be conceived when it is known that, besides elementary and educational works, the whole of the Bible has been translated into it and is now read by thousands.

The Bechwana are divided into numerous tribes, all independent of each other, and each governed by its own chiefs and councillors. The names of some of the principal tribes are Batlapee, Barolong, Bangwaketse, Bakhatla, Bakuena, Bamangwato, and Batauana, the last living near the lake Ngami, first visited by Dr. Livingstone. There are numerous minor divisions, with laws and customs very similar. With the exception of the Balala (the poor inhabiting the country), they are not nomadic, but live in towns of considerable size, containing from 5000 to 40,000. Doubtless, their former warlike habits had the tendency to induce them to congregate for security; for latterly they live, for the sake of agriculture and pasturage, in many formerly uninhabited places.

Though from time immemorial they had been engaged in constant strife with each other, and thus inured to warfare, they were no match for the warlike Kaffre and butchering Zulu and Matebele. Since the introduction of Christianity among the Bechwana, their clannish strifes have ceased; and, being a people of industrious habits, and acute observers of whatever may increase their property and comfort, they go in great numbers to Cape Colony and other parts where they can obtain labour and wages, being prized as servants. This enables them to return enriched to their homes in a few years.

The government of the Bechwana may be said to be both monarchical and patriarchal, and of a comparatively mild character, the king, as chief, seldom exercising his individual authority independent of his councillors and subordinate chiefs. They have their public assemblies (parliaments), but only when circumstances, chiefly in reference to war, require. These are generally characterized by great freedom of speech, and sometimes the king's shortcomings are unsparingly dealt with. All is taken in good part, and there is no interruption of the speaker occupying the arena. The king generally closes the meeting with a long speech, referring to the subjects which each speaker had either supported or condemned, not forgetting to endeavour to clear his own character of any imputation. These public assemblies are now of very rare occurrence.

The Bechwana are well formed, dark brown or bronze, and the majority handsome and not assimilated to the negro type. In most the lower part of the face projects, but the skull exhibits no difference from the European type, and many have broad high foreheads, while there is nothing to be seen like the bent-out legs of the negro. The lips are generally thicker than in Europeans, and many have the nostrils wider. The hair is not wool, but simply hair curled and frizzled. They possess the knowledge of smelting iron and copper ore, and make hoes for husbandry, spears, battle-axes, tools, and a great variety of ornaments, chiefly of brass and other alloys. They prepare the skins of animals, and fabricate a variety of utensils. Agriculture and house-building (in which more skill and labour are required than with African huts in general, the houses being always round and admirably adapted to resist high and stormy winds) are the work of the women, while the men make the garments, hunt, and go to war when required.

The wealth of the Bechwana consists in their cattle, which they tend with the greatest care, manifesting a shrewd discrimination of localities and pasture suited to oxen, sheep, and goats. Living in a warm climate, they require few garments; but, though to a European they appear scantily dressed, both sexes are strictly decent, and are disgusted by the comparative nudity of the Kaffre and Matebele. Circumcision is practised, and for that purpose youths are selected from 10 to 13 years of age; these retire from the towns, the place in which they are being considered sacred till the season of seclusion, a month or more, is over, when they are allowed to return to their friends, and are looked on as men ready to go to war. The people have many ceremonies and superstitions, believing in the influence of witchcraft and charms, but no one of these has the most remote reference to religion. They have no knowledge whatever of idols, or anything intended to represent an invisible power, and consequently have nothing of a religious character. They do not possess a vestige of worship. With regard to a divine Being their ideas are vague in the extreme. The name *morimo*, from *mo*, a personal pronoun, and *rimo*, from *gorimo* (above), instead of being applied to something or some one heavenly—the Creator, Upholder, and Ruler of all—is applied to something that does harm, that inflicts death, or, according to some, a noxious creature that sometimes emerges from a hole to do mischief. So little do the natives care about it, that it never enters into their minds to have recourse to a charm, or anything of a fetish character, to ward off the influence it might be thought to possess. They never allow their thoughts to pierce beyond the moment of death, which is to them the finale of man's existence. Among some of the interior nations there is a belief in the manes of dead kings of note, but not of the commonalty. Dr. Moffat was once present when Moselekatse, the king of the Matebele, in a meeting in the midst of his nobles, in the dark, consulted the spirit of Machobane, his long deceased father. Whatever worship the Bechwana of old may have had, they have none now, not even of any of the animals—the fish, crocodile, monkey, &c.—from which some of the tribes are named. They have a superstitious dread of some things, which, in most if not in all cases, originates with the rainmaker. This is a notable character among all the interior tribes, and possesses supreme influence over the native mind. He has only to speak and it is done, whatever his orders may be. He pretends to give medicine to the clouds, and has recourse to all sorts of tricks and demands on his impatient dupes in order to gain time. Very frequently, when all fails, he falls a sacrifice to their wrath.

The country of the Bechwana south of the tropic of Capricorn is healthy, and admirably suited for pulmonary complaints. The temperature ranges from zero to 105°, and when it exceeds this, as it sometimes does, heavy thunderstorms follow, and not unfrequently hail falls of great size. The principal products are a variety of species of millet (*Holcus Sorghum*), kidney beans, pumpkins, water melons, sweet reed, &c.

The resources and capabilities of the country are small. Hitherto the exports have been principally ostrich feathers, ivory, and cattle; but the first two are become very scarce since the introduction of the horse and rifle. The elephant is now found principally in the regions where the tsètse fly abounds, and where horses cannot live, while the ostrich betakes itself to the deserts. (R. M.)

BECK, or BEEK, DAVID, an eminent portrait painter, born in 1621, at Arnheim in Guelderland. He was trained by Vandyck, from whom he acquired the fine manner of pencilling and sweet style of colouring peculiar to that great master. He possessed likewise that freedom of hand and readiness, or rather rapidity of execution, for which Vandyck was so remarkable, insomuch that when King Charles I. observed the expeditious manner of Beck's painting, he exclaimed, "Faith! Beck, I believe you could paint riding post." He was appointed portrait-painter and chamberlain to Queen Christina of Sweden, and he executed portraits of most of the sovereigns of Europe to adorn her gallery. He lived in the highest favour with his royal mistress, and with difficulty obtained a short leave of absence from her court. He died soon after (1656) at the Hague, not without suspicion of having been poisoned.

BECKER, WILHELM ADOLF, a classical archæologist of distinction, was born at Dresden in 1796. He was at first destined for a commercial life, but was, in 1812, sent to the celebrated school at Pforta, whence, in 1816, he passed to the University of Leipsic. Here he had the good fortune to study under the famous Hermann. After holding subordinate posts at Zerbst and Meissen, he was, in 1836, appointed extraordinary professor of classical archæology at Leipsic; and six years later he was raised to the professorship of antiquities in the same university. He died at Meissen in September 1846. The works by which Becker is most widely known are the *Gallus, oder römische Scenen aus der Zeit des Augustus*, 1838, and the *Charicles, oder Bilder altgriechischen Sitte*, 1840. The author shows not only a complete mastery of Greek and Roman antiquities, but a very happy faculty of imparting life to the dry bones of the science. Both works have been translated into English. Perhaps more useful for scholars is the great *Handbuch der röm. Alterthümer*, 5 vols. (1843–64), completed after Becker's death by Marquardt, and of which a second and enlarged edition is now in course of publication.

BECKET, or À BECKET, THOMAS. See À BECKET, vol. i. p. 31.

BECKFORD, WILLIAM, an English author, the son of Alderman Beckford, who was noted for his manly reply to George III. on the presentation of an address from the city of London, was born in 1761. At the age of nine he inherited a large fortune from his father; and in early life he travelled in Italy, Sicily, Spain, and Portugal, and resided some time near Cintra, where he had a princely residence. He afterwards returned to England, and after selling his old house of Fonthill began to build a magnificent residence there, on which he expended in about eighteen years the sum of £273,000. This, together with its splendid library and pictures, he sold to Mr Farquhar in 1822; but soon after one of the towers, 260 feet high, fell, destroying part of the villa in the ruins. Beckford, however, began the erection of another lofty structure on Lansdowne-hill, near Bath, where he continued to reside till his death in 1844. He was a powerful and original writer. His first work, *Biographical Memoirs of Extraordinary Painters*, which appeared in 1780, was a slight sarcastic *jeu d'esprit*. In 1784 he published in French the singular tale entitled *History of the Caliph Vathek*, which soon afterwards appeared in English, and has taken its place as one of the finest productions of richly luxuriant imagination. In 1834 his first Continental tour appeared under the title of *Letters from Italy, with Sketches of Spain and Portugal*, a work never, perhaps, surpassed for striking description and refined sarcasm. His latest production, published in 1835, was entitled *Recollections of an Excursion to Alcobaza and Batallia in* 1794. All these works exhibit cultivated taste and a remarkable power of vivid description. He left two daughters, the eldest of whom was married to the 10th duke of Hamilton.

BECKMANN, JOHANN, the author of the *History of Inventions*, was born in 1739 at Hoya in Hanover, where his father was postmaster and receiver of taxes. His mother, who was left a widow before he was seven years of age, sent him to school at Stade; and in 1759 he repaired to the University of Göttingen with the intention of studying theology, which, however, he soon abandoned in favour of natural science. The death of his mother in 1762 having deprived him of his former means of support, he accepted, at the offer of Busching, the professorship of natural history in the Lutheran Academy, St Petersburg. This office he soon relinquished, and journeyed through Sweden, where he inspected the manner of working the mines, and formed the acquaintanceship of Linnæus at Upsala. In 1766 he was appointed professor at Göttingen. There he lectured on various arts and on political and domestic economy, and was in the habit of leading his students into the workshops that they might acquire a practical as well as a theoretical knowledge of different processes and handicrafts. While thus engaged he determined to trace the history and describe the present condition of each of the arts and sciences on which he was lecturing, being perhaps incited by the *Bibliothecæ* of Haller. But even Beckmann's industry and ardour were unable to overtake the amount of study necessary for this task. He therefore confined his attention to several practical arts and trades; and to these labours we owe his *Notices on the History of Discoveries in the Common Arts of Life*,—a work in which he relates the origin, history, and recent condition of the various machines, utensils, &c., employed in trade and for domestic purposes. In 1772 Beckmann was elected a member of the Royal Society of Göttingen, and he contributed valuable scientific dissertations to its proceedings until 1783, when he withdrew from all further share in its work. After having been admitted into almost all the learned societies of Germany, and after having impressed on the minds of his numerous students a tendency to pursuits of practical utility, Beckmann died on the 3d of February 1811. His works display great natural sagacity, as well as profound and varied research. Besides the *History of Inventions* he wrote an interesting, but unfinished, *History of the Earliest Voyages made in Modern Times*, and produced editions of a work ascribed to Aristotle, of the *Wonderful Histories* of Antigonus Carystius, and of Marbodius's *Treatise on Stones*. These editions display a rare union of physical knowledge with philological learning. Beckmann was a man of extreme modesty; and his candour and sincerity, as well as his affability to those who studied under him, were acknowledged with one consent by his colleagues and his scholars.

BEDARRIEUX, a town of France, in the department of Hérault, situated on the River Orb, with a station on the branch railway from Béziers to Graissesac. It is a neat and well-built town, and carries on a variety of industries, among the most important of which are the weaving of cotton and woollen cloth and the manufacture of hats, paper, leather, and oil; while at Clairac in the neighbourhood there are glass-works and a copper-foundry. Most of the produce is exported to Africa and the Levant. Not far from the town there is a thermal establishment open all the year round. In the end of the 18th century the population was only 250; in 1872 it was 8985.

BEDDOES, THOMAS, a physician and scientific writer, was born at Shiffnall, in Shropshire, 13th April 1760.

From his infancy he was remarkable for his love of books. His father, who was a tanner, wished him to follow the same calling; but, mainly through his grandfather's recognition of his abilities, he was educated for one of the learned professions. After studying at Bridgnorth grammar school and Plymhill, in Staffordshire, he entered, when about sixteen years of age, at Pembroke College, Oxford. There he proved himself an excellent linguist, while especially devoting himself to science. Having taken his bachelor's degree at twenty-one, he studied at London for the medical profession under Sheldon. In 1783 he became master of arts, and in 1784 he removed to Edinburgh, where he remained about three years. In 1784 he published a translation of Spallanzani's *Dissertations on Natural History*, and in 1785 produced a translation, with original notes, of Bergman's *Essays on Elective Attractions*. He took his degree of doctor of medicine at Oxford in 1786, and, after visiting Paris, where he became acquainted with Lavoisier, was appointed reader in chemistry at Oxford University. His lectures there attracted large and appreciative audiences; but his advocacy of the French Revolution exciting a clamour against him, he resigned his readership in 1792, and took up his abode with a friend at Ketley, in Shropshire. While resident there he published *Observations on the Nature of Demonstrative Evidence*, in which he maintains that geometry is founded on experiment, and the *History of Isaac Jenkins*, a story which powerfully exhibits the evils of drunkenness, and of which 40,000 copies are reported to have been sold. He endeavoured for many years subsequently to realize his project of a pneumatic institution, in which the efficacy of certain gases in curing diseases could be tested. While working for this object he was assisted by the father of Maria Edgeworth, Richard Lovell Edgeworth, one of whose daughters became his wife in 1794. He was ultimately enabled, by the liberality of Wedgwood, to establish the proposed institution (1798), and was fortunate in securing as its superintendent Mr (afterwards the famous Sir Humphrey) Davy, who had already given proofs of uncommon endowments, and many of whose discoveries were made in its laboratory. Among the first results of the pneumatic institution was the discovery of the chemical properties of nitrous oxide, in regard to which, as in many other cases, Beddoes showed himself over-sanguine and speculative. The original aim of the institution was gradually abandoned; it became an ordinary sick-hospital, and was relinquished by its projector in the year before his death, which occurred in 1808. Beddoes was a man of great powers and wide acquirements, which he directed to noble and philanthropic purposes. He strove to effect social good by popularizing medical knowledge, a work for which his vivid imagination and glowing eloquence eminently fitted him. In his manner of theorizing he considerably resembled his contemporary, the once celebrated Erasmus Darwin. Besides the writings mentioned above, he was the author of *Political Pamphlets* (1795–97), a popular *Essay on Consumption* (1779), which won the admiration of Kant, an *Essay on Fever* (1807), and *Hygeia, or Essays Moral and Medical* (1807). A life of Beddoes by Dr John E. Stock was published in 1810.

BEDDOES, Thomas Lovell, a modern English dramatist of peculiar and almost unique genius, was the son of the preceding, and was born at Clifton, 20th July 1803. He received his education at the Charter House, and subsequently at Pembroke College, Oxford, at both of which places he displayed a rugged independence of character, combined with eccentricity of demeanour and an aversion to the ordinary course of study. While still an undergraduate, he published his *Bride's Tragedy*, a piece less characterized by originality than his subsequent performances, and altogether in the taste of the Elizabethan revival of the day initiated by the publication of Lamb's *Specimens*. The notice it obtained from Barry Cornwall and other representatives of this school, encouraged him to devote himself altogether to the cultivation of dramatic poetry; and he speedily produced a number of superb fragments, ranging down from the ambitious but unfinished sketches for tragedies to be entitled *Torrismond* and *The Second Brother*, to short descriptive passages of a few lines each, unsurpassed for originality of conception and condensed force. His genius, unfortunately, though highly poetical, was in no respect dramatic; he entirely lacked the power of constructing a plot and deducing character from action; and his endeavours to achieve a complete work proved abortive until 1829, when the strangely fascinating but fantastic and incoherent drama of *Death's Jest-Book, or The Fool's Tragedy*, was laboriously put together from a series of abortive attempts. By this time Beddoes had become a resident in Germany, and a zealous student of physiology, which, by affording another outlet for that intense curiosity respecting the mysteries of life and death which had hitherto been the mainspring of his poetical efforts, greatly contributed to repress the external manifestations of his genius. Dissatisfaction with his tragedy, which he never cared to publish during his lifetime, and the gradual disuse of his native language, conspired to reduce him to silence. He led for several years an unsettled life on the Continent, devoted to anatomical research, and actively participating in liberal and democratic movements in Germany and Switzerland, until his death in 1849 from the effects of an accident. His literary remains were published in 1851 by his friend Mr Kelsall, with a most interesting memoir, and copious selections from his graphic and striking correspondence, which is distinguished by all the characteristics of his verse. Beddoes is a poet for poets, and few other readers will enjoy him. He is "of imagination all compact;" his works scarcely contain a single passage of purely subjective feeling. He is, perhaps, the most concrete poet of his day; the most disposed to express sentiment by imagery and material symbolism. In this he resembles Keats, and may be termed a Gothic Keats, the Teutonic counterpart of his more celebrated contemporary's Hellenism. The spirit of Gothic architecture seems to live in his verse, its grandeur and grotesqueness, its mystery and its gloom. His relation to the Elizabethan dramatists, moreover, is nearly the same as that of Keats to the Elizabethan pastoral poets; but the resemblance is one of innate temperament: he borrowed nothing, either from his Elizabethan precursors or the chief objects of his admiration among his contemporaries, Keats and Shelley. The want of constructive power which mars his dramas is even more prejudicial to his lyrics; but some few songs, where the right key-note has been struck from the first, rank among the most perfect in our language. The leading features of Beddoes's personal character were uncompromising independence, sterling integrity, and a thorough disdain for the opinion of the world. His life was entirely devoted to ideal aims, and his tastes were of the most simple and philosophic character. The asperity of his demeanour repelled strangers, but he was highly valued by the few whose intimacy he condescended to encourage.

BEDE, Beda, or Bæda (commonly called The Venerable Bede), the father of English history, the most learned Englishman and most eminent writer of his age, was born about the year 673, in the neighbourhood of Monkwearmouth, in the N.E. of the county of Durham. The story of his life is told by himself at the conclusion of his most famous and most important work: "Thus much of the Ecclesiastical History of Britain, and more especially of the English

nation, as far as I could learn either from the writings of the ancients, or the tradition of our ancestors, or of my own knowledge, has, with the help of God, been digested by me, Bede, the servant of God, and priest of the monastery of the blessed apostles Peter and Paul, which is at Wearmouth and Jarrow; who being born in the territory of that same monastery, was given, at seven years of age, to be educated by the most reverend Abbat Benedict, and afterwards by Ceolfrid; and spending all the remaining time of my life in that monastery, I wholly applied myself to the study of Scripture; and, amidst the observance of regular discipline, and the daily care of singing in the church, I always took delight in learning, teaching, and writing. In the nineteenth year of my age I received deacon's orders; in the thirtieth, those of the priesthood. . . . From which time, till the fifty-ninth year of my age, I have made it my business, for the use of me and mine, to compile out of the works of the venerable Fathers, and to interpret and explain according to their meaning these following pieces" (a list of his writings follows). The two associated monasteries here mentioned were founded by Benedict Biscop on the lands between the Wear and the Tyne granted to him by King Ecgfrith. This learned and pious abbot was "the first person who introduced in England constructors of stone edifices, as well as makers of glass windows" (Will. of Malmesb.) But a greater honour attaches to him as having collected in his visits to Rome a large quantity of valuable books, which, deposited in the noble buildings he erected, had much to do with the extensive learning of his celebrated pupil. Bede, after three years at Wearmouth, removed with the Abbot Ceolfrid to the newly-founded Jarrow monastery, where he pursued to the close of his life those studies in every department of literature and science within his reach, the results of which we have in his numerous works.

Bede's industry was marvellous, alike in acquiring and in communicating his stores of knowledge. Besides the usual manual labours of the monastery, the duties of the priest, and his additional occupation as a teacher, he succeeded in writing upwards of forty distinct treatises, which together form what may be looked upon as an early encyclopædia. Of these treatises twenty-five are on Biblical subjects, including commentaries on most of the books of the Old and New Testament and the Apocrypha. The remainder consist of lives of saints and martyrs; lives of the *Abbats of this Monastery;* his *Ecclesiastical History of our Island and Nation;* treatises on *The Nature of Things*, astronomy, chronology, arithmetic, medicine, philosophy, grammar, rhetoric, poetry, music; together with a *Book of Hymns*, and a *Book of Epigrams in heroic or elegiac verse.* While exhibiting little original thought or discovery, except in his historical works, and partaking of the credulity of his time, Bede excels in good judgment, and in thoroughly digesting and clearly arranging and expounding, in simple Latin, what he gathered in his wide range of reading in classical and theological authors. His Biblical works are principally made up of extracts from the Fathers, especially from St Augustine—his interpretations following the allegorical mode of the Middle Ages, as suggested by his own declaration: "He who knows how to interpret allegorically will see that the inner sense excels the simplicity of the letter, as apples do leaves." The scientific treatises are founded on the Bible, and the science of the ancients as contained in such writers as Pliny. Bede's historical works, on the other hand, and especially his great historical work, are remarkable for the patience indicated in the search after all trustworthy sources of information, for his careful statement of these various sources, for the sincerity and love of truth manifest throughout, and for the pleasant artlessness with which the story is told.

In the pursuit of knowledge Bede declined the dignity of abbot; for, he said, "the office demands household care, and household care brings with it distraction of mind, which hinders the prosecution of learning." But his reputation as a scholar, combined with "aptness to teach," made very famous the school of Jarrow, where it is recorded 600 monks, besides strangers from a distance, were at one time in attendance. The influence and authority of the modest teacher on Tyneside were acknowledged throughout the West of Europe, of which Northumbria became now for a period the literary centre. By the renown of its schools, its libraries, and its learning, chiefly represented by him, that kingdom had some recompense for the height of military glory it had reached in Bede's youth, and from which it had recently fallen at Nechtansmere. Pope Sergius, by a letter to Ceolfrid, sought Bede's presence and counsel at Rome, but it is almost certain the invitation was not acted upon. In another way, we can scarcely doubt, he efficiently helped the Papal court. Born about ten years after Rome gained her final victory over Iona at the Synod of Whitby, and four years after Theodore arrived at Canterbury to complete the ecclesiastical conquest, the character and writings of Bede must have strengthened the dominion of the hierarchy in the North of England. His positive efforts may have been confined to his three treatises on the time of celebrating Easter—one of the main questions in dispute. But indirectly, his historical works had the same tendency, exalting, as they do, the missionaries from Italy, while not ignoring the zealous labours of the followers of Columba. In himself, too, the people of Northumbria, the scene of contest, beheld one who brought honour to them as a fellow-countryman,—honour for which, at the same time, they were indebted to the now dominant church that had given him his training and opportunities of study. History, confirmed by the evidence of his writings, is loud in praise of Bede's humble piety as well as his learning. A long letter of his pupil Cuthbert has been preserved, giving a simple and touching account of his death, which probably took place in 735. Though "he suffered in his stomach, and drew his breath with pains and sighs," he was full of thanksgiving and rejoicing, singing psalms, conversing with his pupils, and dictating an Anglo-Saxon translation of the Gospel according to John. He was buried in the church at Jarrow, but his bones were stolen by a monk from Durham and placed beside those of St Cuthbert. There they continued until the middle of the 12th century, when they were enclosed in a splendid shrine by Bishop Pudsey. This shrine was demolished and the relics scattered in the reign of Henry VIII., there only remaining now at Durham the Latin inscription, which concludes with the well-known line—

"Hac sunt in fossa Bedæ venerabilis ossa."

The origin of the title "Venerable" cannot be traced, but it appears as early as 836; and succeeding ages have gladly owned the justness of the appellation. For centuries his theological and educational works held a high position as authorities and even as text-books. The chief monument of his labours and erudition is his *Ecclesiastical History*, which gives us the most and the best of our knowledge of the history of England until 731, four years before his death.

Bede's works were published in 6 vols. fol., Paris, 1544, 1545, 1554, editions now rare; 8 vols. fol., Basel, 1563, and Cologne, 1612 and 1688; 12 vols. 8vo, with English translation, edited by Dr Giles, London, 1843-44. MSS. of the *History* are at Cambridge and Brit. Mus. Alfred translated it into Anglo-Saxon. Other translations are by Stapelton, 1565; John Stevens, 1723; and W. Hurst, 1814. Stevens's translation improved, edited by Giles, is published along with the *Anglo-Saxon Chronicle*, in Bohn's Antiquarian Library, 1847. All the historical works translated by Stevenson form part of vol. i. of *The Church Historians of England*, 1853-54.

BEDELL, William, bishop of Kilmore and Ardagh, in Ireland, was born at Black Notley, in Essex, in 1570. He was educated at Cambridge, took orders, and after leaving the university, settled for some years as clergyman in Bury St Edmunds. He was then appointed chaplain to Sir H. Wotton, English ambassador at Venice In that town Bedell remained for eight years, acquiring great reputation as a scholar and theologian. He translated the *Book of Common Prayer* into Italian, and was on terms of closest friendship with Sarpi (Fra Paolo), the famous historian of the Council of Trent. In 1615, some time after his return to England, he was appointed to the rectory of Horningsheath, in Suffolk, which he held for twelve years. He was then called to the provostship of Trinity College, Dublin, and relinquished that office after two years for the united bishoprics of Kilmore and Ardagh. As bishop he won the respect and love of his people by the uprightness and purity of his conduct. He set himself diligently to reform the abuses of his diocese, and personally undertook the duties generally discharged by the bishop's lay chancellor. In 1641, when the Protestants were being massacred in the Irish rebellion, Bedell's house was not only left untouched, but became the place of refuge for many fugitives. In the end, however, the rebels insisted upon the dismissal of all who had taken shelter in his house, and on the bishop's refusal he was seized and imprisoned with some others in the ruined castle of Loughboughter. Here he was detained for several weeks, and when released, rapidly sank from the effects of exposure on his weakened constitution. He died on the 7th February 1642. His life was written by Burnet.

BEDFORD, the county town of Bedfordshire, a municipal and parliamentary borough and market-town, situated in a fertile vale on both sides of the River Ouse, which is here crossed by a handsome stone bridge of five arches. It is 50 miles N.W. of London, and has excellent railway accommodation as well as a navigable river. It is a station on the main line of the Midland Railway. The town consists chiefly of one long wide street, intersected by smaller ones at right angles. It is well built, and numerous villas and small streets have been erected on the west side since the opening of the Midland main line in 1868. It has five parish churches, four of which contain architectural features of interest. St Paul's has lately undergone considerable restoration, and the tower and spire have been rebuilt. St Peter's has been enlarged, but the ancient tower remains, in which are to be seen examples of Saxon work. St Mary's has a fine Norman tower, but the remainder of the church has at different times been restored. St John's has also been restored, but the original tower remains. St Cuthberts is a recent erection in the Norman style. A district church, dedicated to the Holy Trinity, was opened in 1841. There are also Independent, Methodist, Baptist, Roman Catholic, and other chapels. Bedford, in proportion to its size, has more public endowments than any other place in the kingdom, for which it is chiefly indebted to Sir W. Harper, Lord Mayor of London in 1561, who founded here a free school, and conveyed for its support, and for portioning poor maidens, a piece of ground in London, the surplus, if any, to be given to the poor. This ground has gradually risen in value so as now to produce nearly £14,000 annually. It supports grammar, modern, preparatory, and other schools. Formerly much of this large endowment was appropriated to eleemosynary purposes, which did not tend to the elevation of the character of the people; but since the enactment of a scheme of the Endowed Schools Commission in 1874, the whole amount is expended upon the schools, except a small proportion for the endowment of forty-five alms-houses. The grammar school has eight exhibitions of £70 per annum each, at Oxford, Cambridge, or Dublin. Among the public buildings are the schools, the shire-hall, the jail, the infirmary, the county library and assembly rooms, and the new corn exchange. The commercial prosperity of this town is greatly aided by the works of the Messrs Howard and others, for the manufacture of agricultural implements, &c. There are also manufactures of straw and lace in the neighbourhood. Bedford is governed by a mayor, six aldermen, and eighteen councillors; and it sends two members to parliament. It is exceptionally well provided with sanitary appliances, having a new complete system of sewerage and water-works; and the sewage is conveyed to a farm about a mile from the town and utilized at once for growing crops of grass, roots, and corn. Population in 1871, 16,850.

BEDFORD LEVEL, the name given to a flat district on the eastern coast of England, comprising the greater part (amounting to 450,000 acres) of the marshy district called the *Fens*, the whole Isle of Ely in Cambridgeshire, and a portion of the north of that county, 30,000 acres of Suffolk, 63,000 acres of Norfolk, 57,000 of Huntingdon, about 8000 of Northamptonshire, and the south-eastern portion of Lincolnshire. The extent of the whole tract is 60 miles in length, from Milton in Cambridge to Toynton in Lincoln; its breadth is about 40 miles, from Peterborough in Northampton to Brandon in Suffolk. The boundary on three sides is irregular, giving it something of a horse-shoe shape, with the opening terminated by the sea on the north.

This district obtained its present name from the agreement of Francis earl of Bedford, the principal landholder, and thirteen other adventurers, with Charles I. in 1634, to drain the level, on condition of receiving 95,000 acres of the reclaimed land. The district has within historic times undergone remarkable changes. In the time of the Romans it was a dense forest, which, as a stronghold of the Britons, those invaders destroyed. It then became a swamp, through which the lazy waters of the Ouse, the Welland, the Nene, and Wisbeach, crept to the sea. In the 13th century the sea here, as in other parts of N.W. Europe, burst its boundaries, and the inundated land became a pestilential swamp. The first attempt to drain this morass seems to have been made in the year 1436, and embankments and ditches were formed at a great expense. These, however, were swept away during the ensuing winter by the flooding of the River Ouse. Another partial attempt at drainage was made by Bishop Moreton in the reign of Henry VII., but this also proved a failure. An Act was passed in the 44th year of Queen Elizabeth for effecting its reclamation; but the first effectual attempt at reclaiming it was not made until 1634, as already mentioned, and many embankments and canals were constructed at various intervals at an expense above one million sterling. Three years after the agreement of the earl of Bedford and his partners with the king, after an outlay of £100,000 on the part of the company, the contract was annulled, on the fraudulent plea that the works were insufficient; and an offer was made by King Charles to undertake its completion on condition of receiving 57,000 acres in addition to the amount originally agreed on. This unjust attempt was frustrated by the breaking out of the civil war; and no further attempt at drainage was made till 1649, when the Parliament reinstated the earl of Bedford's successor in his father's rights. After an additional outlay of £300,000, the adventurers received 95,000 acres of reclaimed land, according to the contract, which, however, fell far short of repaying the expense of the undertaking. In 1664 a royal charter was obtained to incorporate the company, which still exists, and carries on the concern under a governor, 6 bailiffs, 20 conservators, and a commonalty, each of whom must possess 100 acres of land in the level, and has a voice in the election of officers. The conservators must each possess not less than 280 acres, the governor and bailiffs each 400 acres. The original adventurers had allotments of land according to their interest of the original 95,000 acres; but Charles II., on granting the charter, took care to secure to the crown a lot of 12,000 acres out of the 95,000, which, however, is held under the directors, whereas the allotments are not held in common, though subject to the laws of the corporation. The level was divided in 1697 into three parts, called the North, Middle, and South Levels—the second being separated from the others by the Nene and Old Bedford rivers.

Since then extensive works have at different times been carried on to complete the drainage of this district; but the most effectual are under the Acts of 1827 and 1829, for "Improving the outfall of the Nene," "The Navigation of the Wisbeach," and "The Embanking of the Salt Marshes between the canal called Kinderley Cut and the sea." Vessels of 200 to 300 tons burden can now

come up to the town of Wisbeach at all tides, and those of from 500 to 800 tons at spring tides. The draining of the lower lands, which, like the Dutch *Polders*, are below low-water mark, was carried on by windmills, but these have now been almost superseded by steam-engines; in the North Level the drainage is effected by sluices. As the result of these extensive operations, the level now abounds in rich pasture and corn lands.

For Map, see Northampton.

BEDFORDSHIRE, one of the south midland counties of England, surrounded by the counties of Buckingham, Northampton, Huntingdon, Cambridge, and Hertford. It is the fourth smallest county, containing only 295,509 acres or 461 square miles. Its extreme length from north to south is about 47 miles, and its width 21 miles. The great Ouse, which flows through the county eastward, is navigable from Bedford to the sea at King's Lynn. The Midland and Great Northern Railways intersect the county, also the Bletchley and Cambridge branch of the London and North-Western. The surface of the county is for the most part level, but the northern half is undulating, with a subsoil generally of boulder-clay and Oxford-clay. A fine tract of land south of Bedford is bounded by a range of lower-greensand running east and west, presenting beautiful woodland scenery, parallel to which, along the Hertfordshire border, the Chiltern chalk range rises to 500 feet above the sea-level and 400 feet above the level of Bedford. The country is generally devoted to corn-growing, but the Ouse valley has a large breadth of rich pasturage, and all along the west side of the Great Northern railway is a sandy loam, on which onions, potatoes, and market produce are grown. Agricultural implement and other engineering works employ about 1000 hands at Bedford and Luton; while the female industry of the county is pillow-lace, and in the south straw-plait. The plait is made up, chiefly at Dunstable and Luton, into hats and bonnets, which are exported to all parts of the world. Luton is the most populous town in the county, slightly exceeding the county town of Bedford. The county rate assessment is £585,840, and the expenditure in 1873 was £11,802. The county belongs to the diocese of Ely, and coincides with the archdeaconry of Bedford. It contains 9 hundreds and 124 parishes. It is in the Norfolk circuit, and assizes are held twice a year. A court of quarter-sessions sits at Bedford, and the petty sessional divisions are seven. Two members are returned to parliament for the county and two for the town of Bedford. The titles derived from the county are that of duke to the house of Russell, and of baron of Bletsoe to the family of Lord St John, and the largest landowners are the duke of Bedford and Mr Whitbread of Southill. The most distinguished residence in the county is Woburn Abbey (duke of Bedford), near the town of that name. It was formerly a Cistercian abbey, granted at the Reformation by Henry VIII. to the family of Russell, the fourth duke of which house erected the present edifice. It is a very grand and capacious pile, situated in an extensive park, and is furnished with a large and valuable collection of paintings and statues. Luton Hoo is also an extensive mansion, which was reconstructed and improved for the third earl of Bute by the brothers Adam. A library, 146 feet in length, furnished with a valuable collection of books, and a large selection of paintings of some of the first masters, chiefly of the Italian school, are its distinguishing ornaments. Besides these there are other mansions which are highly deserving of notice, especially that of Mr Whitbread at Southill; Wrest Park, belonging to the Dowager Countess Cowper; Hawnes House, to the Rev. Lord John Thynne; Sutton, to Sir John M. Burgoyne; and Oakley House, to the marquis of Tavistock.

There are a general infirmary and fever hospital at Bedford; near Arlesey is the Three Counties Lunatic Asylum (for Beds, Herts, and Hunts) provided for 685 patients; at Carlton is the juvenile county reformatory; at Kempston the county school (300 boys), also the Military Brigade Depôt. Connected with the county are the militia (18th Light Infantry), the duke of Manchester's cavalry volunteer corps, and the rifle volunteers.

The population of the county stood at the four last decennial enumerations as follows:—

Year.	Males.	Females.	Total.	Houses.
1841,	52,190	55,746	107,936	21,964
1851,	59,941	64,537	124,478	25,461
1861,	63,940	71,347	135,287	28,314
1871,	69,046	77,211	146,257	32,099

In the year 1871 the number of agricultural labourers was 15,962, of straw-plaiters 23,508 (90 per cent. being females), and of lacemakers 6051, all females. The towns and their populations in 1871 were as follows:—Luton, 17,317; Bedford, 16,850; Leighton-Buzzard, 4696; Dunstable, 4558; Biggleswade, 4244.

When the Romans landed in Britain Bedfordshire formed a portion of the district of the Cattieuchlani, whose sovereign or chief, Cassibelenus or Cassivelaunus, commanded the united forces which opposed Julius Cæsar. When, in the year 310, the Emperor Constantine ruled the whole island, and divided it into five provinces, Bedfordshire was included in the third division called *Flavia Cæsariensis*, and remained so till the final abandonment of Britain by the Romans. Under the Saxon heptarchy it formed part of the kingdom of Mercia, until with the rest of the island it was united to the kingdom of the West Saxons, which was divided by Alfred into counties, hundreds, and tythings, when this county first received its present name.

There are many remains of Roman, Saxon, and Norman antiquities. Traces of a Roman station are to be seen at Sandy near Potton, and at Maiden-Bower near Dunstable. Leighton-Buzzard, or Beaudesert, is supposed to have been a Roman camp. The ancient Icknield and Watling Streets passed through the county; and the remains of both may be definitely traced, as well as of some others constructed by the Romans.

BEDNOR, a town of Hindustán, in the territories of the Rájá of Mysore, situated in 13° 50′ N. lat., and 75° 6′ E. long. In 1645 the seat of government of the Rájás of Ikeri was transferred to this place; as the inhabitants of the former capital removed with the court, Bednor became a city of great importance, containing, it is said, 20,000 houses, besides huts. It was taken and plundered by Haidar Alí in 1763, who ordered it to be called Haidarnagar. It is still, however, known by its original name of Bednor. At that time it was estimated at 8 miles in circumference. In 1783 it surrendered to a British detachment under General Matthews, but being shortly after invested by Tipu Sultán, the garrison capitulated on condition of safe conduct to the coast. Tipu violated the stipulation, put General Matthews and the principal officers to death, and imprisoned the remainder of the force. At Tipu's death it contained 1500 houses, besides huts. The district of Bednor is situated on the summit of that range of hills, the Western Gháts, which overlooks the provinces of Canara and Malabar. In consequence of its elevation above the sea, and the steepness of the mountain chain, which rises like a wall to the height of 4000 or 5000 feet, the clouds of the south-west monsoon are here intercepted, and their contents precipitated on the table-land in deluges of rain, which continue for six months in the year, and are extremely favourable to vegetation. Its products are pepper, betel-nut, cardamums, and sandal wood. Cattle of small size are also bred. The imports are salt, rice, cocoa-nuts, oil, turmeric, and cotton cloths.

BEDOUINS, the portion of the Arab race that live in the desert in tents. See ARABIA, vol. ii. p. 246, *ff*.

BEE

THE bee, from its singular instincts, its active industry, and the useful products resulting from its labours, has, from the remotest times, attracted general attention and interest. No nation upon earth has had so many historians as this remarkable class of insects. The patience and sagacity of the naturalist have had an ample field for exercise in the study of the structure, physiology, and domestic economy of bees; their preservation and increase have been objects of assiduous care to the agriculturist; and their reputed perfection of policy and government have long been the theme of admiration, and have supplied copious materials for argument and allusion to the poet and the moralist in every age. It is a subject that has been celebrated by the muse of Virgil, and illustrated by the philosophic genius of Aristotle. Cicero and Pliny record that Aristomachus devoted sixty years to the study of these insects; and Philiscus is said to have retired into a remote wood, that he might pursue his observations on them without interruption. A very great number of authors have written express treatises on bees; periodical works have been published relating exclusively to their management and economy; and learned societies have been established for the sole purpose of conducting researches on this subject.

In so complicated a branch of natural history, correct observation and induction require laborious and long-continued efforts. But, on the subject of bees, the inquirer after truth had, besides, many obstacles to encounter from the very general diffusion of errors, which had been transmitted without due examination from one author to another. The history of the opinions of successive writers sufficiently proves how gradual and slow has been the growth of an accurate knowledge of these insects,—what is now known being the result of the persevering labours of ages. The accumulation of curious and interesting facts, indeed, which has accrued from the researches of Swammerdam, Maraldi, Reaumur, Schirach, Huber, Dzierzon, and Von Siebold, constitutes almost a new science. It will therefore be proper, in this place, to give a connected and systematic account of the natural history of the bee; and the principal features of internal conformation will be described along with the particular functions. Our descriptions will apply, more especially, to the common and best-known species, the *Apis mellifica*, which is the one particularly prized on account of the rich products it affords.

We shall begin with a brief account of the different sorts of bees inhabiting the hive, and of the respective offices of each; we shall then proceed to consider their comparative physiology, including the leading particulars relating to the functions of their various organs, sensitive powers, instincts, secretions, and diseases. We shall also explain the theory of parthenogenesis and the impregnation of queens, and shall follow the bees in their different labours, from the period when the swarm has settled in a new habitation,—detailing the complex structure of their combs, their curious processes of architecture, and the pains they bestow on rearing their progeny, and in sending forth new swarms; and, in the last place, we shall notice the best systems of modern bee-keeping, and give some account of hives and apiarian implements.

The leading feature in the natural history of bees, and one which distinguishes them from almost all other insects, is their singular distribution into three different kinds, constituting to all appearance so many different modifications of sex. The drone (fig. 1), which is characterized by a thicker body, a round head, a more flattened shape, and more obtusely terminated abdomen, within which are contained the male organs of generation, is undoubtedly the male of the species. It is distinguished also by the absence of a sting, and by the humming noise that accompanies its flight. The queen-bee (fig. 2), which is unequivo-

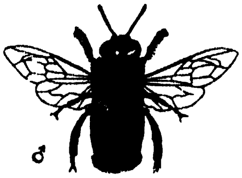

FIG. 1.—Drone.

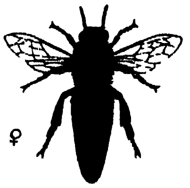

FIG. 2.—Queen-Bee.

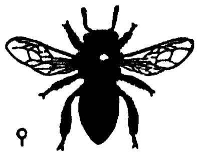

FIG. 3.—Worker Bee.

cally recognized as a female, is larger than any of the others, has the abdomen of greater length, and is provided with a sting and two ovaria of considerable size. The worker bees (fig. 3) compose the third class, and are distinguished by the smallness of their size, their lengthened proboscis, the peculiar structure of their legs and thighs, which are adapted to the collection of certain materials obtained from vegetables, and by the apparent absence of every trace of generative organs,—we say *apparent*, because, as will be shown, rudiments of ovaria do exist, which, however, are not perceptible without a very minute and careful dissection. Till recently the worker bees were regarded as devoid of sex, and were accordingly termed *neuters*. It is their function to perform all the laborious offices for the community, to construct the interior of their habitation, to explore the country in search of nourishment and other materials, to collect and bring them to the hive, and apply them to different purposes, to attend upon the queen, and supply all her wants, to defend the hive from the attacks of depredators, and to carry on hostilities against the various enemies of the tribe. The life of the queen is chiefly engrossed with the duties of laying eggs. The drones producing neither wax nor honey, and depending on the rest for their subsistence, are idle spectators of the others' labours. They appear to be formed only for the momentary but important duty of impregnation, since they perish when this purpose is accomplished. There is commonly only one perfect queen existing at a time within each hive, and she usually appears to be treated by all the other bees with every mark of affection and of deference. The number of workers is very different in different hives; sometimes there are only a few thousands; at other times from twenty to forty, or even fifty thousand. The drones, even in the spring, seldom compose more than one-thirtieth or one-fortieth of the whole; and, at other seasons, there are none to be found in the hive when a fertile queen is present. In order to form some estimate of the number of bees which can occupy a certain space, Hunter counted what number of drowned bees could be contained in an alehouse pint, and found it to be 2160; so that if a swarm were to fill two quarts, their numbers would be nearly 9000. Reaumur, with the same view of ascertaining their numbers, employed the more accurate method of weighing them; he found that a collection, weighing one ounce, consisted of 336 bees, and, therefore, that 16 ounces, or one pound, would consist of 5376 bees.

Notwithstanding the difference in conformation, instincts, and offices between the queen-bee and the workers, it is now established on the most incontrovertible evidence that they both originally proceed from the same kind of egg or larva, which is capable of being converted, according to

circumstances, either into a worker or a queen. It has been proved that the former, although exhibiting no appearance of sexual organs on a superficial examination, are in reality females, and have the rudiments of these organs, which, however, not being developed, are incapable of exercising their proper functions, although it sometimes happens that they become sufficiently so to enable a worker to lay unfecundated eggs. It may be remarked that the idea of the worker bees being radically females had been suggested long ago by Dr Warder in his *Monarchy of Bees*, in which he terms them "True Amazons;" but no attention had been paid to his opinion. The real merit of this great discovery, which affords a key to a multitude of hitherto inexplicable facts, unquestionably belongs to Schirach. When first announced to the world it was received with suspicion by the greater number of naturalists, and with complete incredulity by others. It was, indeed, at variance with the whole tenor of the observations of Swammerdam, Maraldi, and Reaumur. Wilhelmi, the brother-in-law of Schirach, though an eye-witness of the experiments from which this theory had been deduced, for a long time refused to admit the doctrine, but at length became one of its most strenuous supporters. It is noticed in a vein of sarcastic ridicule by John Hunter in his otherwise excellent paper on bees in the *Philosophical Transactions*. Needham wrote a *Memoir* for the Imperial Academy of Brussels in 1777 for the express purpose of refuting it, and he then inveighs in strong language against those naturalists who had deigned to give it the least countenance. Bonnet, after exercising a laudable scepticism, and making a diligent inquiry, in which he displays a genuine spirit of philosophy, yielded a reluctant assent. But the truth of the doctrine has since been placed beyond the reach of controversy by a multiplied series of observations and experiments in different parts of Europe and America.

Nutrition. In considering the physiology of the bee, the first function that claims our notice is that of nutrition. The food of bees is principally of two kinds, namely, the fluid secretions of vegetables contained in the nectaries of the flowers, and the dust of the anthers, which has been termed by botanists the pollen, but which, when collected by the bees, has received a variety of appellations, such as farina, bee-bread, &c. Occasionally, however, we find bees feeding upon other saccharine substances besides honey, such as honey-dew, syrup, &c.

Organs for collecting food. The organs by which they collect food are extremely complex, comprising instruments adapted to the reception of liquid aliment as well as those fitted for the division of solid materials. Reaumur has given a most elaborate description of these organs, and corrects some errors into which Swammerdam had fallen. For the purpose of taking up fluids, bees are provided, in common with all hymenopterous insects, with a long and flexible proboscis or **Proboscis.** trunk, which may be considered as a lengthened tongue, though, strictly speaking, it is formed by a prolongation of the under lip. It is not tubular, as Swammerdam had supposed, but solid throughout; and the minute depression at its extremity is not the aperture of any canal through which liquids can be absorbed. The trunk of the bee performs strictly the office of a tongue, and not that of a tube for suction; for when it takes up honey or any other fluid aliment, the under or the upper surfaces are more immediately applied to it, and rolled from side to side, and the bee thus licks up what adheres to it, while the extremity of the trunk is frequently not applied at all to the substance taken up. The trunk is supported on a pedicle, which admits of being bent back or propelled forwards, and thus can retract or stretch out the trunk to a considerable extent. Protection is given to it by a double sheath; the external part consisting of two scales furnished by the expansion of one of the portions of the labial palpi, and the internal formed by the prolongation of the two external portions of the jaw. The whole member thus consists of five principal parts, on which account Fabricius termed it *lingua quinquefida*.

Mandibles. For the purpose of mechanically dividing solid materials, the mouth is furnished with two strong mandibles and four palpi; they are but little employed in eating, but are of great use in enabling the insect to seize and break down hard substances for other purposes. In the worker bee all these parts are of larger dimensions than in the other kinds. The teeth are two in number, and have the form of concave scales with sharp edges; they are fixed to the ends of the jaws, and play horizontally as in other insects. Reaumur describes and delineates a large aperture above the root of the proboscis, which is so surrounded with fleshy parts as not to be readily seen unless the proboscis be extended and bent downwards. This he considers as the mouth or orifice of the gullet; on the upper side of which, and of course opposite to the root of the proboscis, a small fleshy and pointed organ is seen, which he regards as the tongue, assisting in the deglutition of the food. Through this orifice, it is presumed, all the aliment, whether liquid or solid, passes; the former being conveyed to it by the trunk, which, by its contractile power, presses forward the fluids it has collected between itself and the inner sheath, and the latter being received directly after its comminution by the teeth, behind which it is situated. Latreille, however, whose authority is great on a point of this nature, thinks that Reaumur has deceived himself with regard to such an aperture, and disbelieves its existence. He conceives that the food simply passes on by the sides of the tongue, finding its way from thence into the œsophagus and so on to the stomach.

Stomachs. The bee has two stomachs. The first is a large transparent membranous bag, pointed in front and swelling out into two pouches behind. It performs an office in some respects analogous to that of the crop in birds; for it receives and retains for a time the fluid of the nectaries, which does not appear to differ in any respect from honey. Hunter observes that whatever time the contents of this reservoir may be retained he never found them altered so as to give the idea of digestion having taken place. The coats of this reservoir are muscular, by which means it is capable of throwing up the honey into the mouth, so that it is regurgitated into the honey cells or imparted to other bees. None of it ever passes out from the extremity of the trunk as Swammerdam had believed. For the purpose of digestion a second stomach is provided, which takes its origin from the middle of the two posterior lobes of the former, and is of a lengthened cylindrical shape. Its communication with the intestine is not direct, but takes place by a projecting or inverted pylorus, thickest at its most prominent part, with a very small opening in the centre, of a peculiar construction. This inward projecting part is easily seen through the coats of the reservoir, especially if full of honey. A similar kind of structure takes place at the communication of the first with the second stomach, and having the properties of a valve, must effectually prevent all regurgitation from the latter into the former.

Collection of pollen. The pollen, or fertilising dust of flowers, is collected by the bees for the purpose of feeding the young. It is stored in the cells until required, and then partly digested by the nurses with honey, and a kind of chyle formed of it. When natural pollen cannot be obtained the bees will eagerly take farina, either of rye, chestnuts, or pease, as a substitute, which appears to answer the same purpose. The bees, by means of the pencil of hair which grows on the tarsi, first collect a certain quantity of pollen, and then

knead it together into a ball, and place it in the space situated at the middle joint or tibia of the hinder leg, which has been termed the basket. This portion of the leg is smooth and concave, somewhat like the bowl of a spoon, with stout hairs of moderate length rising from its left edge and nearly straight. Other hairs on the right side are much longer and are curved, rising up with a high arch and crossing more than half the width of the hollow, making a large basket-like enclosure for a load of pollen. In order to gather large quantities at once, the bees are sometimes observed to roll their bodies on the flower, and then brushing off the pollen which adheres to them with the feet, form it into two masses, which they dispose of as before mentioned; and it is said that in moist weather, when the particles of pollen cannot be readily made to adhere, they return to their hive dusted all over with pollen, which they then brush off with their feet. The part in Nature's economy thus unconsciously performed by the bee in common with other insects is most important. By this means the pollen is carried from flower to flower, or from the stamens to the pistils, and plants are made fertile which without such aid would often remain barren.

Wax. It was long the received opinion that wax was but a modification of pollen, which required for this conversion only a slight pressure and a kind of kneading by the feet of the bees. But it has been completely proved, by the researches of Duchet, Hunter, and Huber, that wax is a secretion from the abdomen of the bee, and that it depends not at all on the pollen which the insect may consume (indeed, it is doubtful if it consumes any), but on the quantity of honey or other saccharine substance which it receives into its stomach. The first light thrown on this subject was in a letter of Wilhelmi to Bonnet in 1768, in which he says that wax, instead of being ejected by the mouth, exudes from the rings which enclose the posterior part of the body. Of this we may satisfy ourselves by drawing out the bee from the cell in which it is working with wax, by means of the point of a fine needle; and we may perceive, in proportion as the body is elongated, that the wax will make its appearance under the rings in the form of small scales. Duchet, in his *Culture des Abeilles*, gives a full statement of the principal circumstances attending the production of wax, which he very justly ascribes to the conversion of honey into this substance in the body of the bee. These facts appear to have been entirely overlooked till the subject was again brought forward by Hunter, in his paper in the *Philosophical Transactions* for 1792. Huber was engaged in prosecuting his inquiries on this subject at the same period with Hunter, and discovered, in 1793, the existence of regular receptacles or pouches, from the coats of which the wax is secreted, and within which it accumulates till its edges raise the scales, and become apparent externally. These plates of wax are withdrawn by the bee itself, or some of its fellow-labourers, and are applied in a manner hereafter to be described.

Huber has shown, by a series of well-conducted experiments, that, in a natural state, the quantity of wax secreted is in proportion to the consumption of honey, but that an equal or even greater quantity will be formed if the bee be fed on a solution of sugar in water. Warmth and rest promote this process of secretion; for the bees, after feeding plentifully on saccharine food, hang together in a cluster without moving, for several hours, at the end of which time large plates of wax are found under the abdominal rings. This happened when bees were confined and restricted from any other sort of nourishment, whilst those that were fed on pollen and fruits alone did not produce any wax. In the second volume of Huber's *Nouvelles Observations sur les Abeilles*, he describes minutely the anatomy of the pouches or receptacles for the wax, which are parts peculiar to the working bees, being totally absent in the males and queens. The cavities are lined with a membrane, which presents a number of folds, forming an hexagonal net-work, not unlike the appearance in the second stomach of ruminant quadrupeds, and evidently destined to perform the office of secretion.

Poison. Among the secretions peculiar to the bee, the poison which is poured into the wounds made by the sting deserves to be noticed. It is said to owe its mischievous efficacy to certain pungent salts. If a bee is provoked to strike its sting against a plate of glass, a drop of poison will be discharged; and if this is placed under a microscope, the salts may be seen to concrete, as the liquor dries, into clear, oblong, pointed crystals. **Sting.** The sting consists of a finely-pointed tubular instrument, open along the whole length of its upper surface, this opening being closed by two slender horny barbs each having about ten serrations on its outer edge. These barbs are not projected in advance of the sting as usually described, neither are they within the sting, but complete its outer tubular surface, down the centre of which the poison is injected from a little bag at the root of the sting. The serrations prevent the worker bee from withdrawing its sting from an enemy; and, consequently, it is torn from the body, with a portion of the intestines, causing the death of the bee.

Functions of respiration. Respiration is effected by means totally different from those which are usual in the higher classes of the Animal Kingdom. As the blood, or fluid corresponding to the blood, cannot be presented to the air in any separate organ, the air must be conducted to the blood wherever such a fluid is met with. For this purpose tracheæ, or air-tubes, having several external openings or spiracles, are made to ramify like arteries, and are distributed in an infinite number of branches to every part of the body. The condition of a hive of bees in which many thousand individuals, full of animation and activity, are crowded together in a confined space, having no communication with the external air but by means of a very small aperture in the lowest part, which aperture is frequently obstructed by a throng of bees passing in and out during sultry weather, would without some precautions be of all possible conditions the one least favourable to life. Bees cannot exist in an impure atmosphere any more than creatures of a larger growth. **Ventilation of the hive.** And on examining the air of a populous hive it is found scarcely to differ in purity from the surrounding atmosphere. The means by which this is effected observation has shown is by the rapid vibration of the bees' wings, a certain number being told off to imitate the action of flying, for which purpose they fasten themselves with their feet to the floor of the hive, so that the whole effect of that impulse which, were they at liberty, would carry them forwards with considerable velocity is exerted on the air, which is therefore driven backwards in a powerful current. Some bees occasionally perform these ventilating motions on the outside of the hive, near the entrance, but a still greater number are employed in this office within doors. Sometimes twenty are thus occupied at once, and each bee continues its motions for a certain time, occasionally for nearly half an hour, and is then relieved by another, which takes its place. So rapid a motion of the wings is thus produced that they cannot be seen except at the two extremities of the arc of vibration, which is at least one of 90°. This is the occasion of that humming sound which is constantly heard from the interior of the hive when the bees are in a state of activity. The immediate cause of these actions is probably some impression made on their organs by the presence of vitiated air, for a bee may be made to ventilate itself by placing near it substances which have to it an unpleasant odour.

The connection between an active respiration and a high

Temperature of the hive.

temperature is remarkably exemplified in bees, among which, in consequence of their collecting together in large numbers, the heat is not readily dissipated, and admits also of being easily ascertained by the thermometer. Hunter found it to vary from 73° to 84° Fahr.; and Huber observed it on some occasions to rise suddenly from about 92° to above 104°.

Sensitive powers.

The physiology of the external senses in a class of animals of a nature so remote from our own species must necessarily be very imperfectly understood by us. The infinite diversity of character presented by the different tribes of insects, as well as of other animals, naturally suggests the idea that external objects produce on their sentient organs impressions widely different from those which they communicate to ourselves. The notions we form of their senses must not only be liable to great inaccuracy, but may often be totally inadequate representations of the truth. A finer organisation and more subtile perceptions would alone suffice to extend the sphere of their ordinary senses to an inconceivable degree, as the telescope and the microscope have with us extended the powers of vision. But they possess in all probability other organs appropriated to unknown kinds of impressions, which must open to them avenues to knowledge of various kinds to which we must ever remain total strangers. Art has supplied us with many elaborate modes of bringing within our cognizance some of the properties of matter which nature has not immediately furnished us with the means of detecting. But who will compare our thermometers, spectroscopes, or hygrometers, however elaborately constructed, with those refined instruments with which the lower orders of animals, and particularly insects, are so liberally provided?

Functions of the antennæ.

The antennæ, which are so universally met with in this class of animals, are doubtless organs of the greatest importance in conveying impressions from without. Their continual motion, the constant use which is made of them in examining objects, the total derangement in the instincts of those insects which have been deprived of them, point them out as exquisite organs of sense. To impressions of touch arising from the immediate contact of bodies they are highly sensitive, but their motions evidently show that they are affected by objects at some distance. They are, no doubt, alive to all the tremulous movement of the surrounding air, and probably communicate perceptions of some of its other qualities. Composed of a great number of articulations, they are exceedingly flexible, and can readily embrace the outline of any body that the bee wishes to examine, however small its diameter. Newport, in a paper published in the *Transactions of the Entomological Society*, says he is convinced from experiments that the antennæ are auditory organs; and that however varied may be their structure, they are appropriated to the perception and transmission of sound. The majority of modern physiologists and entomologists coincide in this view, and the weight of authority in favour of it is certainly very great, comprising as it does Sulzer, Scarpa, Schneider, Borkhausen, Bonsdorf, Carus, Straus-Durckheim, Oken, Burmeister, Kirby and Spence, Lespès, and Hicks. Nevertheless, other eminent entomologists, as, for instance, Lyonet, Küster, Robineau-Desvoidy, Vogt, and Erichson, regard these organs as the seat of smell. The question may be considered as yet undetermined, and it is possible that they are the organs of some sense of which we know nothing, and which we consequently cannot describe. It is by these instruments that the bee is enabled to execute so many works in the interior of the hive, from which the light must be totally excluded. Aided by them it builds its combs, pours honey into its magazines, feeds the larvæ, and ministers to every want which it appears to discover and judge of solely by the sense of touch. The antennæ appear also to be the principal means employed for mutual communication of impressions. The different modes of contact constitute a kind of language which seems to be susceptible of a great variety of modifications, capable of supplying every sort of information for which they have occasion.

Vision.

The sense residing in the antennæ appears to be on many occasions supplementary to that of vision, which in bees, as in other insects, is less perfect than in the larger animals. During the night, therefore, they are chiefly guided in their movements by the former of these senses. In full daylight, however, they appear to enjoy the sense of vision in great perfection. A bee alights unerringly on the flowers in search of nectar or pollen, and as truly at its own hive's entrance on its arrival there. When returning from the fields to its hive it seems to ascertain the proper direction by rising with a circular flight into the air; it then darts forward with unfailing precision, passing through the air in a straight line with extreme rapidity, and never failing to alight at the entrance of its own hive, though whether its course be determined by vision alone we are unable to say.

Perceptions of temperature.

Their perceptions of heat and cold are extremely delicate. The influence of the sun's rays excites them to vigorous action. Great cold will reduce them to a state of torpor, and inferior degrees of cold are unpleasant to them; a temperature of 40° Fahr. will so benumb a bee as to deprive it of the power of flight, and it will soon perish unless restored to a warmer atmosphere. When, however, bees are in the usual winter's cluster in the hive, they will bear a very great degree of cold without injury. In America hives often stand where the external temperature is as low as 20° below zero, and from the condensed vapour within the hive, the bees may be found in a solid lump of ice, and yet, with returning spring, they awake to life and activity. The degree of cold which bees can endure has not been ascertained, though it is no doubt considerable. They survive the winter in many cold parts of Russia, in hollow trees, without any attention being paid to them; and there hives are frequently made of the bark of trees, which does not afford a very complete protection from the effects of frost. Many bees which are thought to die of cold in winter die in reality of famine or damp. A rainy summer and cold autumn often prevent their laying in a sufficient store of provisions; and the hives should, therefore, be carefully examined in the after-part of the season, and the amount of food ascertained. Mr White judiciously observes, that bees which stand on the north side of a building whose height intercepts the sun's beams all the winter will waste less of their provisions than others which stand in the sun; for, coming forth seldom, they eat little, and yet are as forward in the spring to work and swarm as those which had twice as much honey left with them the preceding autumn. They show by their conduct that they are sensible of changes in the state of the weather for some time before we can perceive such alterations. Sometimes when working with great assiduity they will suddenly desist from their labours, none will stir out of the hive, while all the workers that are abroad hurry home in crowds, and press forward so as to obstruct the entrance of the hive. Often, when they are thus warned of the approach of bad weather, we can distinguish no alteration in the state of the atmosphere. Gathering clouds sometimes produce this effect on them; but perhaps they possess some species of hygrometrical sense unconnected with any impression of vision. Huber supposes that it is the rapid diminution of light that alarms them, for if the sky be uniformly overcast they proceed on their excursions, and even the first drops of a shower do not make them return with any great precipitancy.

Taste and smell.

Their taste is, perhaps, the most imperfect of their senses. They use scarcely any discrimination in the collection of honey from different flowers. They are not repelled by the scent or flavour of such as are extremely offensive to our organs, and scruple not to derive supplies from such as are highly poisonous. In some districts in America it is well known that honey acquires in this way very deleterious properties. The qualities of honey are observed to vary much according to the particular situation from which it is obtained. In their selection of flowers they are guided by the quantity of honey they expect to meet with, and in no respect by its quality. That gathered from ivy blossoms in England is sometimes so bitter and nauseous as to be useless for our eating, although the bees consume it readily. But their smell must be sufficiently acute to enable them to discover honey at great distances, and in concealed situations direct experiment has indeed proved this to be the case. Huber found that they proceeded immediately towards boxes which contained honey concealed from view; and such, in fact, is the situation of the fluid of the nectaries in flowers. Some odours, and especially all kinds of smoke, are highly obnoxious to them; and this is also the case with ammonia and other volatile chemical agents, upon receiving the impression of which they immediately set about ventilating themselves in the usual manner. The odour of the poison of their sting produces similar effects, exciting them to immediate rage and hostility. It has been observed that bees recognize the presence of a stranger in their hive by the smell; and in joining two stocks into one, if the bees are united without precautions, a battle will probably ensue. To obviate this bee-keepers are in the practice of strongly scenting both families by means of peppermint, tobacco smoke, or other strong-smelling agent; this overpowering the bees' natural scent, they are unable to distinguish their own party from the intruders, and peace is insured. The sense of vision does not appear to aid them, for where Ligurians are added to common black bees the effect is the same, although in colour the two varieties are very different. In the introduction of an alien queen to a stock it is also usual to imprison the new sovereign within the hive which she is to rule until she has acquired the peculiar scent of her future subjects, who will then make no objections to her, while had she been at once set at liberty she would probably have met her death.

Although it is clear that insects possess the power of smell, yet the particular organ of this sense has never been accurately ascertained, and the opinions of naturalists have been much divided on the subject. These opinions have been supported more by arguments drawn from the analogy of what happens in other classes of animals than by direct experiment on insects themselves. We know that in all animals respiring by means of lungs, the organs of smell are placed at the entrance of the air-passages; and it has often been concluded that in like manner the stigmata, or the orifices of the air-tubes, are the seat of this sense in insects. Huber's opinion was that in the bee this sense resides in the mouth itself, or in its immediate vicinity. Here, indeed, would be its proper station if this faculty be intended, as we may reasonably suppose it to be, to apprise the individual of the qualities of the food prior to its being eaten. When the mouth of a bee was plugged up with paste, which was allowed to dry before the insect was set at liberty, it remained quite insensible to the same odours to which it had before manifested the strongest repugnance.

Hearing.

It is generally supposed that bees possess the sense of hearing. The common practice of making a loud noise by drums and kettles in order to attract a swarm is founded on this supposition. But the evidence is by no means conclusive, for we find that they are not disturbed by a loud clap of thunder, or by the report of a gun, or by any other noise that may happen to arise round them. Sir John Lubbock, who has made a great many observations in this direction, says that he could never find them take notice of any sound he made even when it was close to them. He tried them with a violin, dog whistle, shrill pipe, and set of tuning forks, also by shouting, &c., close to their heads, but in spite of his utmost efforts the bees took no notice, not even by a twitch of the antennæ showing they heard. It is, however, certain that they are capable of emitting a variety of sounds which appear expressive of anger, fear, satisfaction, and other passions; and it would seem that they are even capable of communicating certain emotions to one another in this manner. Huber observed that the young queens not yet liberated from their cocoons set forth a peculiar piping sound, and this is answered by the old queen, who apparently must hear the note of her aspiring rival.

A certain cry or humming noise from the queen will strike with sudden consternation all the bees in the hive, and they remain for a considerable time motionless and stupified. Hunter has noticed a number of modulations of sound emitted by bees under different circumstances, and has instituted an inquiry concerning the means employed by them in producing these sounds; for an account of this see his paper in the *Philosophical Transactions.*

Instinct.

If the function of sensation in insects be involved in doubt and obscurity, the knowledge of those more interior faculties, which are the springs of voluntary action, is hid in still deeper mystery. Buffon refuses to allow bees any portion of intelligence, and contends that the actions we behold, however admirably they are directed to certain ends, are in fact merely the results of their peculiar mechanism. Other philosophers, such as Reaumur and Brougham (*Works*, vol. vi.), have gone into the opposite extreme, and have considered them as endued with extraordinary wisdom and foresight, as animated by a disinterested patriotism, and as uniting a variety of moral and intellectual qualities of a higher order. The truth, no doubt, lies between these overstrained opinions; but it is nevertheless extremely difficult to decide in what degree these respective principles operate in the production of the effects we witness. The term *instinct* should properly be regarded, not as denoting a particular and definite principle of action, whose operation we can anticipate in any new or untried combination of circumstances, but as expressive of our inability to refer the phenomena we contemplate to any previously known principle. Thus the actions which an animal performs in obedience to the calls of appetite are not properly said to be instinctive; nor can the term be applied to actions which are the consequence of acquired knowledge, and of which the object is with certainty foreseen by the agent. But when an animal acts apparently under a blind impulse, and produces effects useful to itself or to the species, which effects it could not have previously contemplated as resulting from those actions, it is then customary to say that it is under the guidance of instinct, that is, of some unknown principle of action. It will be proper, therefore, to keep this distinction in view in judging of the voluntary actions of the lower animals.

In no department of natural history is it more necessary to be aware of the proper import of the term instinct, than in studying the phenomena presented by the bee; for nowhere is it more difficult to discriminate between the regular operation of implanted motives and the result of acquired knowledge and habits. The most striking feature of their history, and the one which apparently lays the foundation for those extraordinary qualities which raise them above

the level of other insects, is the disposition to social union. It may in general, indeed, be remarked, that animals which associate together so as to form large communities, display a higher degree of sagacity than those which lead a solitary life. This is especially observable among insects. The spider and *Formica leonis* may exhibit particular talents, or practise particular stratagems in the pursuit and capture of their prey; but their history is limited to a single generation, and embraces none of those interesting relations which exist between individuals composing the gregarious tribes, such as the ant, the wasp, and the bee. Among these we trace a community of wants and desires, and a mutual intelligence and sympathy, which lead to the constant interchange of good offices, and which, by introducing a systematic division of labour, amidst a unity of design, leads to the execution of public works on a scale of astonishing magnitude. The attachment of bees to their hive, which they defend with a courage and self-devotion truly admirable, their jealousy of intruders, their ready co-operation in all the labours required for the welfare of the community, their tender care of their young, the affection and homage which they bestow on their queen, imply qualities such as we could hardly persuade ourselves could animate a mere insect, on which we are in the habit of proudly looking down as placed in one of the lowest orders of created beings.

We shall content ourselves at present with these general observations, as the instances which serve to illustrate their moral and intellectual character belong properly to the history of the different processes they follow in the construction of their combs, the hatching and rearing of their progeny, and the mode of conducting their migrations. To these subjects, therefore, we shall now proceed; and in order to present the most connected and complete account of their economy, we shall begin the history from the period when a new swarm has just occupied a hive, and when all the arrangements for their habitation, and the construction of the cells in which their eggs and provisions are to be deposited, are yet to be effected.

Preparation of the hive.

The first care of the worker bees, on their settlement in their new abode, is to clean it out thoroughly. While one set of bees is thus employed, another is distributed about the country in order to procure the proper materials for blocking up the small holes and chinks of the hive, and for laying a firm foundation for the edifice which is to be constructed within it. The substance which is principally employed in this preliminary stage is *propolis*, a species of glutinous resin, of an agreeable aromatic odour, and reddish-brown colour, in process of time becoming darker, and acquiring a firmer consistence. According to the analysis of Vauquelin (*Mém. Soc. Agricult. Departem. Seine*), it is composed chiefly of resin, with a small proportion of wax, and of acid and aromatic principles. It is soluble in alcohol, ether, and oils, both fixed and volatile, and tinges the solvent of a beautiful red colour. Cadet has since ascertained in it the presence of benzoic and gallic acids. Reaumur had not been able to discover from what plants the bees collect this substance. Riem asserts that it is chiefly from pines and other trees of the fir kind. The observations of Huber have assisted in the solution of this question. On placing branches of the wild poplar tree before the hive, he found that the bees eagerly seized upon the varnish which exudes from the buds; and examining the chemical properties of this varnish, he identified it with the propolis with which the inside of the hive is lined.

Propolis.

The propolis adheres so strongly to the legs and feet of the bee which has collected it, that it cannot be detached without the assistance of its fellow-labourers. For this purpose the bee that is loaded presents its legs to the workers in the hive, which carry off with their jaws this adhesive substance, and immediately apply it, while yet ductile, all round the interior of the hive, and particularly over all the projecting parts; hence its name, of Greek derivation, signifying *before the city*. In like manner all the foreign bodies that are introduced into the common habitation and are too heavy for removal are covered over with this resinous substance. If a snail, for instance, should happen to introduce itself into the hive, after despatching it with their stings, they encrust it over with propolis.

Construction of the combs.

The next object of their labours is the construction of the combs, the future receptacles for the eggs with which the queen is pregnant and which are now to be laid. The material employed is wax; and the bees, for the purpose of secreting this, are actively employed in collecting honey. When they have filled their crops with honey they hang together in a thick cluster from the top of the hive, and thus remain in a state of inactivity for a considerable period, during which time the secretion of wax is proceeding. It may be seen collected in laminæ under the abdominal scales, whence it is removed by the hind legs of the bee, transferred to the fore legs, and from thence taken up by the jaws. In this operation they are often assisted by their companions, who even sometimes directly seize upon the wax from under the abdomen of those who are before them. When a sufficient quantity of material has thus been collected together, the process of building is commenced; but in order to understand the subsequent operations it is necessary to have a correct idea of the form of the cells which compose the combs. We shall, therefore, proceed to give some account of the structure when it has attained its perfect state.

Forms of the combs.

The combs of a bee-hive are formed in parallel vertical strata, each of which is about an inch in thickness, the distance between the surfaces of adjoining strata being about half an inch, a space which allows for the passage of the bees over both surfaces. The combs generally extend the whole breadth of the hive, and nearly the whole length from the top to the bottom. They consist of thin partitions which enclose hexagonal cells, opening on both surfaces of the comb and closed by a partition which is common to those on both sides, and occupies the middle distance between the two surfaces. This partition is not, however, a plane, but is composed of a collection of rhombs. Three and sometimes four of these rhombs incline to one another at a certain angle from the bottom of each cell, which thus has the shape of a flattened pyramid, of which the base is towards the mouth of the cell. The geometric form of each individual cell is therefore a hexagonal prism, terminated by a trihedral pyramid, the three sides of which are rhombs which meet at the apex by their obtuse angles, and, forming oblique angles with the sides of the prism, truncate a portion of these, and convert them from rectangles, which they would be in a regular prism, into trapeziums. Of the two angles of these trapeziums adjoining the base of the pyramid one must be acute and the other obtuse, the acute angle of one trapezium being next to the acute angle of the adjoining trapezium, and the obtuse angle being in like manner next to another obtuse angle of the preceding trapezium; so that in going round the base we meet with pairs of acute and of obtuse angles alternately succeeding each other. The two adjoining acute angles of the trapezium are adjoining to two of the terminal rhombs which here present their acute angles, so that at these points a solid angle of four planes is formed, all the angles being acute. Each pair of obtuse angles of the trapezia, on the other hand, are adjacent to the obtuse angle of one of the rhombs only, thus composing a solid angle of three planes of which the angles are all obtuse; and these two kinds of solid angles succeed one another

alternately all round the base of the pyramid, there being three of each kind and six in all. The axis of each cell coincides not with the axis of the cell on the opposite surface, but with one of its angles; so that each of the three obtuse angles at the base of the terminal pyramid corresponds to the central parts of three of the cells on the opposite side, and each of the sides of the pyramid which closes a cell on one side contributes in part to the enclosing of three of the cells on the opposite side. We may easily satisfy ourselves that such is the case by piercing the centres of each of the three planes which close the bottom of a cell with a pin, when on turning the comb the three pins will be found to have passed into three different cells on the opposite side.

Geometric properties of the cells.

A structure of this kind is obviously the one of all others calculated to afford the greatest space for each cell with the same quantity of materials. It is easy to perceive, in the first place, that in a plane surface, when a number of small spaces are to be divided by partitions, the hexagonal form is the one which comprehends the largest space compatible with the extent of the lines which enclose them; for the equilateral triangle, the square, and the regular hexagon, are the only regular forms that admit of being joined together in the same plane without leaving interstices; and the proportion of the area to the periphery in every polygon increases as the figure consists of a greater number of sides, and is, therefore, greater in the hexagon than in either of the other two. The truth of this proposition was perceived by Pappus; and even its application to the subject of the honeycomb was made by that ancient geometrician. But the determination of the form and inclination that should be given to the partitions that close the bottom of the cells, and which may, of course, belong equally to those on both sides of the comb, is a problem much more complicated and difficult of solution. It has exercised the skill of several modern mathematicians of great eminence. Reaumur proposed to König, pupil of the celebrated Bernouilli, and an expert analyst, the solution of the problem:—To find the construction of a hexagonal prism terminated by a pyramid composed of three equal and similar rhombs (and the whole of given capacity), such that the solid may be made with the least possible quantity of materials;—which in other words was asking him to determine the angles of the rhombs that should cut the hexagonal prism so as to form with it the figure of the least possible surface, since the hexagon being given, this decided both their dimensions and their intersections with the sides of the cell. Maraldi had previously measured the angles of the rhombus and found them to be 109° 28′ and 70° 32′ respectively; but König was not aware of this until after he had solved the problem, and assigned 109° 26′ and 70° 34′ as the angles, when he had sent him the *Memoirs of the Academy of Science for* 1712, containing Maraldi's paper; and König was equally surprised and pleased to find how nearly the actual measurement agreed with the result of his investigation. The measurement of Maraldi is correct, and the bees have, with rigorous accuracy, solved the problem, for the error turns out to be in Konig's solution. The construction of cells, then, is demonstrated to be such that no other that could be conceived would take so little material and labour to afford the same room.

Boscovich, who has also given a solution of the same problem, supposes that the equality of inclination of the planes gives greater facility to the construction of the comb, and might, therefore, be a motive of preference, independently of the greater economy of wax. Maclaurin has offered a solution of this problem, and has demonstrated by simple geometry, that the most advantageous form is that which results from the supposed equality of the three plane angles forming the solid angles at the base. He estimates the saving of wax by partition so constructed, above what would be required for a flat partition, at one-fourth of the wax which would be wanted to complete the truncated sides of the cells, so as to form them into rectangles. L'Huillier, in the *Memoirs of the Berlin Academy*, has given a demonstration which is remarkable for its simplicity, and for its involving none but elementary propositions; he values the economy of wax at $\frac{1}{51}$ of the whole wax employed. Le Sage, as appears from the life of that philosopher by Professor Prevost, has shown that this celebrated problem reduces itself to the finding of the angle at which two planes with a given inclination (such as 120°) can be cut by a third plane, so as to make all the angles resulting from the section equal to one another.

But a more essential advantage than even the economy of wax results from this structure, namely, that the whole fabric has much greater strength than if it were composed of planes at right angles to one another; and when we consider the weight they have to support when stored with honey, pollen, and the young brood, besides that of the bees themselves, it is evident that strength is a material requisite in the work.

Buffon's theory of the formation of the combs.

It has often been a subject of wonder how such diminutive insects could have adopted and adhered to so regular a plan of architecture, and what principles can actuate so great a multitude to co-operate, by the most effectual and systematic mode, in its completion. Buffon has endeavoured to explain the hexagonal form by the uniform pressure of a great number of bees all working at the same time, exerted equally in all directions in a limited space; and illustrates his theory by supposing a number of similar cylinders compressed together, and taking the form of hexagonal prisms by the uniform expansion of each. The analogy of the forms produced by the law of crystallization,—of the figures assumed by various organs in the animal and vegetable world, such as the skin of the bat, and the inner coat of the second stomach of ruminant quadrupeds,—is also adduced by this captivating but superficial writer in support of his argument. But however plausible this theory may at first sight appear, it will not stand the test of a serious examination. The explanation he has attempted applies no further than to the inclination of the sides of the cells; but he did not take into account, perhaps from not having studied the subject mathematically, the inclinations and forms of the planes which close each cell, and so curiously conspire on both sides to serve a similar office, while they at the same time accurately fulfil a refined geometrical condition. But it is sufficient confutation of the whole theory to show, that it is directly at variance with the actual process employed by the insects in the construction of their combs.

It might be supposed that bees had been provided by nature with instruments for building of a form somewhat analogous to the angles of the cells; but in no part, either of the teeth, antennæ, or feet, can any such correspondence be traced. Their shape in no respect answers to that of the rhombs, which are constructed by their means, any more than the chisel of the sculptor resembles the statue which it has carved. The shape of the head is indeed triangular, but its three angles are acute, and are different from that of the planes of the cells. The form of the plates of wax, as they are moulded in the pouches in which this substance is secreted, is an irregular pentagon, in no respect affording a model for any of the parts which compose the honeycomb. Hunter, observing that the thickness of the partition was nearly equal to that of the scale of wax, thought that the bees apply these scales immediately to the formation of the partition, by merely cementing them together. Reaumur, notwithstanding the use of glass hives, had not been able to discover the mystery of their process

of architecture, but inferred, from what he saw, that the wax was rejected from the stomach in the form of a white frothy liquor. No naturalist, indeed, prior to Huber, had been able to follow these insects in their labours, on account of their crowding together in a thick mass while they are building; but the expedients resorted to by that philosopher have unfolded the whole process, which he has given with great detail in the second volume of his *Observations sur les Abeilles*. Huber witnessed the whole of their actions, and saw that each bee drew out, with its hind feet, one of the plates of wax from under the scale where it was lodged, and carrying it to the mouth in a vertical position, turned it round, so that every part of its edge was made to pass in succession under the cutting edge of the jaws; it was thus soon divided into very small fragments, while at the same time a frothy liquor was poured upon it from the tongue, so as to form it into a perfectly plastic mass. This liquor gave the wax a whiteness and opacity which it did not possess originally, and rendered it at the same time tenacious and ductile. A quantity of wax thus prepared for use is accumulated, and applied to further the work in the manner we are presently to describe.

But, in considering the process by which the comb is formed, a circumstance should be pointed out, which seems not to have been particularly noticed by any author except Huber, and yet it is one of essential importance in studying this process of architecture, namely, that the cells in the outside row on each side are of a form very different from those of the subsequent rows. As they take their origin from a plane surface, two of the sides necessary to complete the hexagon are cut off by this plane, so that the general form of the orifice is pentagonal; and the bottom of the cells on one side is composed of two equal rhombs only, and on the other side of two trapezoidal planes, with one rhomb. Such a modification of shape was necessary, in order to prepare the way for the regularly-formed cells which were to follow.

The foundations of the combs are laid by the bees raising a solid block or plate of wax of a semicircular form. In this they scoop out a small vertical channel, of the size of an ordinary cell. The sides of this channel are then strengthened by additions of wax. On the opposite side two other channels are formed, one on each side of the plane opposite to the former channel. The extremities of these channels, which at first present a curved outline, are then fashioned into straight walls, forming an angle at each vertex. The bottom of each cell being thus sketched out, the design is completed by raising walls round the sides. Different bees generally work on the opposite sides at the same time, and appear to have some perception of the thickness of the partitions, and of the situation of the opposite walls, in which they are perhaps guided by slight prominences, occasioned by the depressions which correspond to them on the other side; and they scrape off the wax in those places where its thickness is greatest, that is, where the bees on the other side had accumulated materials. In this way, then, in constructing the successive rows, the axis of each cell will be found to occupy the most retiring parts of the partition, and will be opposite to the junction of three of the opposite cells.

Soon after the bees have completed the foundations, and constructed a few of the cells of the central comb, they begin two others, one on each side, at the proper distance, and in this manner continue to form others in succession, in proportion as the former are advanced. Their object at first seems to be to extend the surface of the work so as to admit of the greatest possible number of workers being employed at one and the same time. In this way, then, the work proceeds from all points at once, new cells being begun before the former are completed, so that the whole comb, while it is in progress of construction, has a semi-lenticular shape, broader at the top, and tapering below and towards the sides. It extends downwards, however, more rapidly than in any other direction, and its surfaces do not become parallel to each other till the last stage of the building process. When this is completed, the whole is further strengthened by an additional coating of propolis round the margin of all the cells; and the junctions of every plane, both of the sides and bottoms of the cells, are also soldered together by a lining of the same substance. The edges of the combs are also secured in their situations by being glued to the side of the hive and supported by fresh abutments of propolis. Sometimes a mixture of wax and propolis, manufactured by the bees themselves, is employed as the cementing material. The first coating of this compound substance is denominated *Commosis* by Pliny, and described as having a bitter taste; the second, or the *Pissoceros* of the same author, is stated to be of a thinner consistence, and more adhesive than the former, while the third substance, or *Propolis*, is completely solid.

The cells recently constructed are white, but become gradually darker, and, when very ancient, are almost black. It is therefore easy to distinguish in a hive the successive periods of formation of different portions of the combs. From the researches of Huber, it appears that these variations of colour are not owing to any changes in the wax itself, but to additional coatings of a peculiar varnish, consisting of propolis and a colouring matter. The latter differs materially from propolis, being wholly insoluble in alcohol. It loses its colour by the action of nitric acid or the light of the sun. Its origin has not yet been discovered, nor has the mode in which it is applied been clearly made out, although Huber presumes, from his observation, that the bees spread it by means of their mandibles, since he has seen them rub these against the sides of the cells, and noticed that they acquired a yellow colour from the operation.

Royal cells. Royal cells are only formed when it is necessary that queens should be reared, either from their being required to lead off swarms, or from the fact of the colony being queenless through accidental circumstances.

Cell linings. The comb of the hive may be said to be the furniture and storehouse of the bees, which by use must wear out; but, independently of this, it will in time become unfit for use, by the accumulation of cocoons, which are never removed. These line the whole cell, sides, and bottom. Hunter counted above twenty different linings in one cell, and found the cell about one-quarter or one-third filled up.

Lord Brougham made some interesting observations on the cells of bees. By boiling the comb in alcohol after it had been bred in, he succeeded in dissolving the wax, leaving the lining only, which was found to be an extremely thin transparent or semi-transparent film, resembling gold-beaters' skin, without a wrinkle. The linings from old cells with thick walls kept the shape of the cells most distinctly. They had angles and planes as well defined as those of wax in the new comb, but they did not consist of a single film like the cells where one brood only had been raised. They had one film within another, and could be separated, so that as many as five or six could be extricated from the same cell; each of these had the hexagon form, and the first two, and sometimes three, had the rhomboidal form of the base also, but the innermost ones had the rhombuses less and less distinctly marked, till the last one or two of all had spherical instead of pyramidal bases. The film adhered so closely to the wax as to defend it from the action of the solvent and even from that of heat, preventing it from melting for a considerable time. The film fitted the wax cells so completely that there never was found the least wrinkle or laxity, each being tensely

stretched in all its parts without any interval in any part. The whole of each cell was one entire piece of film going all round the prism and all through the pyramid without any breach, section, or joining; neither maceration nor even boiling in turpentine, ether, or caustic potash had any effect on the film.

A film of the same substance, transparent but considerably thicker, was found to line the queen-cells, assuming the pear or flask-like shape of the wax, and a very remarkable fact was observed. The film was not always in the inside; it sometimes lay imbedded in the wax, at least a layer of wax was laid over it of sensible thickness, indeed considerably thicker than some plates of the common cell, and sometimes much thicker. As a queen-cell is never used but once, never more than a single film can be found in it. How this lining is formed has never been satisfactorily determined, but it must be in one of two ways,—either by the larva forming a cocoon round itself and of an oblong figure inside, sufficient to contain it when it changes its position from a coil perpendicular to the axis of the cell into an oblong worm placed in the axis, or by the larva lining the walls of the cell. In the former case the cocoon, originally made somewhat of the shape of the larva, must afterwards be applied by it or by the chrysalis so as to line and adhere to the walls; in the latter case the walls are lined at first by the act of weaving or spinning. But there are difficulties attending both these hypotheses and the inferences to which they lead—inferences in either case as extraordinary, to say the least, as anything observed in the economy of the bee. If the cocoon is formed loose and round, then, when the transformation takes place, the pupa must press against every part of the cell, so as to apply the film all round and equally in every part. The extraordinary part is the perfect adaptation of the cocoon to the cell. There is no wrinkle whatever. It fits exactly in every part, both the planes and the dihedral angles and the trihedral angles. The extreme fineness of the texture may facilitate its fitting so many different shapes. But how is the size sufficient and not more than sufficient in any one place? If we only consider what extreme complexity and difficulty there would be in forming a cocoon which should increase at every hair's breadth, and increase in a ratio varying at different points, and should, on reaching its maximum size, continue afterwards stationary in dimensions—we shall be convinced how insuperable the difficulties of the workmanship would be to any artist ever so expert or careful. But even this is not all, for as the web is to be afterwards by the supposition applied to the circumscribed walls, the extent of the curved surface of the cocoon inscribed must be less than that of the surface which it is afterwards to line if that curve is wholly concave to the axis, in other words, if it have no points of contrary flexure. In order, therefore, that it may be exactly equal to the walls which it is to fit exactly, the cocoon must be of a form wholly different from that of the larva that made it. It must be convex at some points and concave at others to the larva; it must be loose and baggy, and the progress of its bagging or being loose must vary at every point in order that when applied to the walls it may exactly fit them at every part. The performance of such a work by the larva appears scarcely conceivable. Astonishing as the known and ascertained works of the perfect insect are, this would surpass them in a proportion that might almost be called infinite. If we adopt the second inference, we get rid entirely of the former difficulty; for the operation of forming the film upon the walls is certainly much more easy. With the utmost nicety and precision, there is never a break to be found, and there is no part thicker than the rest, so that but one layer is applied everywhere; and the larva knows so accurately where it has begun as always to leave off on coming round to that point without ever going again over the same ground for half a hair's breadth. The material is also very remarkable. A very high magnifying power shows no threads or separate pieces of any kind; in the great bulk of the texture, it is for the most part solid and perfectly transparent. There are interspersed irregularly a few fibres, but it should seem as if the whole was a mucilage spread over the walls rather than any webs of woven threads. But though the difficulties attending the other theory are not found in this, it has difficulties of a different kind and equally startling. The first that strikes us immediately is the use of the cocoon formed on the waxen walls. The cell was already made, and of the required form and dimensions, in which the larva could be lodged and grow and undergo its transformations. How was the lining it with the film to assist the process? If the cocoon had been of another form and wrapt round the larva, it might have served some such purpose of covering or support; but here the cocoon exactly fits the cell and in nowise alters its form, and only by an exceedingly small portion its capacity. And how are the second and subsequent cocoons to be accounted for? The cell had been already completely lined with the film, and the additional lining could add nothing to the advantage, whatever it was, which the first lining gave the larva and chrysalis. (See Brougham's *Works*, vol. vi. pp. 312–364.)

Different kinds of cells.

Such is the general outline of the architectural labours of the bee. A number of modifications are, however, met with, adapting them to various purposes and to new circumstances. The cells are required to be of different sizes for the nurture of different sorts of larvæ. The smallest, which are also the most numerous, are appropriated to the larvæ of the working bees; a larger sort receive those of the males; and a small number of very large cells are destined for the education of the young queens, and are therefore called royal cells. The first set are generally five and one-third lines in depth, and two and a half in diameter; the second are from seven to seven and a half lines in depth, and three and three-fourths in diameter; while the royal cells are above one inch deep, one-third of an inch wide, and their walls are much thicker than those of any other cells. Other cells, again, are set apart as magazines of honey or of pollen; they are made deeper than the common cells, sometimes as deep as two inches, and their axes are inclined to the horizon, so that their mouths are in the highest part, that their liquid contents may be more easily retained. When these are filled they are closed up by the bees with a wall of wax, and opened only when necessity requires.

Cells of transition.

The regularity of the cells is often disturbed in consequence of the admixture of rows of larger cells with those of smaller dimensions; but the pyramidal partitions are adapted by successive gradations to these changes, so that in many rows of what may be called cells of transition, the bottom presents four planes instead of three, two being trapeziums, and the other two irregular hexagons. These irregularities are met with chiefly in the combs most distant from the central one. When an abundant supply of honey induces the bees to lay up a large quantity in store, they build up for this purpose the walls of common cells, so as to give them a greater depth. The royal cells are often raised from the ruins of a number of other cells, which are destroyed to make room for them; they are usually built on the edge of some of the shorter combs, and often in the very centre of the hive. Sometimes there is but one; at other times as many as sixteen have been counted in the same hive. They are formed of a mixture of propolis and wax; their form is oblong, resembling that of a pear; their position is always vertical, so that

when they rise from the midst of other cells, they are placed against the mouths of those cells, and project beyond the common surface of the comb. They are perfectly smooth on the inner surface, while their outer side is covered with a kind of hexagonal fret-work, as if intended for the foundation of regular cells.

Impregnation.

The impregnation of the queen-bee was formerly involved in the deepest obscurity, and has given rise to a multitude of very fanciful opinions. Some have denied that any intercourse with the male was necessary for the fecundation of the eggs. Swammerdam supposed that the mere effluvia proceeding from the males where they were collected in clusters was sufficiently active to produce this effect by penetrating the body of the female. Huber proved by decisive experiment that no such consequence resulted from these effluvia. Maraldi imagined that the eggs were fecundated by the drones after being deposited in the cells in the same way that the spawn of fishes is rendered prolific by the milt. Mr Debraw of Cambridge gave an account, in a paper published in the *Philosophical Transactions*, of a milk-like fluid he had seen in the cells. But this appearance Huber showed to be a mere optical illusion arising from the reflection of light at the bottom of the cells. When the males are excluded from the hive the queen is as fertile and the eggs as prolific as when they are present. Hattorff supposed that the queen is capable of impregnating herself, an opinion which was supported by Schirach and Wilhelmi, and was even favourably received by Bonnet, as it in some measure accorded with his discoveries respecting the aphis. Linnæus was of opinion that an actual union between the sexes took place, and Reaumur fancied he had seen this happen within the hive. There is, however, great reason to think he was mistaken. It has since been clearly proved that copulation takes place in the air during flight, and if the queen is confined to the hive either by bad weather, or malformation or mutilation of her wings, although she may be surrounded by drones, she never becomes impregnated; and if she does not find a mate within three weeks of her birth, the power of sexual intercourse seems to become lost. If a hive containing a virgin queen be attentively watched on fine days the queen will be observed preparing for her matrimonial flight, and after having attentively surveyed her home so as to be able to recognize it again she flies to a considerable height in the air; and if her errand is successful, in half an hour she returns to the hive with unequivocal proofs of the intercourse that has taken place, for she has in fact robbed the drone of the organs concerned in this operation; and the drone, thus mutilated, is left to perish on the ground. From its being necessary that the queen should fly to a distance in order to be impregnated, Huber infers the necessity of a great number of drones being attached to the hive, that there may be a sufficient chance of her meeting one of them during her aërial excursion.

Parthenogenesis.

The phenomenon that sometimes occurred in a bee-hive, of the queen laying eggs that produced males only, had for ages puzzled philosophers without any satisfactory solution, and it was reserved for Dzierzon to promulgate a new and startling theory of reproduction, which, in the words of its distinguished author, is said to have "explained all the phenomena of the bee-hive as perfectly as the Copernican hypothesis the phenomena of the heavens." Dzierzon first expressed his views upon the reproduction of bees in the year 1845. The principal points of this theory may be shortly expressed thus:—*1st*, That the queen (female bee), to become good for anything (*i.e.*, to breed *workers*), must be fertilized by a drone (the male), and that the copulation takes place only in the air; that drone eggs do not require fecundation, but that the co-operation of the drone is absolutely necessary when worker bees are to be produced; that in copulation the ovaries are not fecundated, but the seminal receptacle (or spermatheca), a little vesicle or sac opening into the oviduct, which in the young queen is filled with a limpid fluid, is saturated with semen, after which it is more clearly distinguishable from its white colour; and that the supply of semen received during copulation is sufficient for her whole lifetime. The copulation takes place once for all, and (as already stated) only in the open air; therefore no queen which has been lame in her wings from birth can ever be perfectly fertile, that is, capable of producing both sexes, as copulation never takes place in the interior of the hive. *2d*, All eggs which come to maturity in the ovaries of a queen-bee are only of one and the same kind, and when they are laid without coming in contact with the male semen, become developed into male bees. This theory of Dzierzon's has since been amply confirmed by numberless experiments, although what power the queen possesses (or how she exercises it) of determining what eggs shall receive fecundation and what not, is yet a mystery. Certain it is that when the queen lays an egg in a drone cell, a drone is produced; and Von Siebold, who made many most skilful microscopical examinations of eggs, affirms that among fifty-two eggs taken from worker cells, examined by him with the greatest care and conscientiousness, thirty-four furnished a positive result, namely, the existence of seminal filaments, in which movements could even be detected in three eggs; and among twenty-seven eggs from drone cells, examined with the same care and by the same method, he did not find one seminal filament in any single egg either externally or internally. On the passage of the eggs from the ovary through the oviduct they pass the opening of the spermatheca, from which some eggs receive a portion of the seminal fluid,—these produce workers; other eggs pass without receiving the fluid,—these produce drones. What it is that governs the deposition or non-deposition of the seminal fluid on the egg is unknown. It has been suggested that the smaller diameter of the worker cells exerts some mechanical pressure on the queen's organs, which may cause the seminal fluid to be extruded as the egg passes, while the drone cells being larger this pressure is not by them exerted, and the egg passes unfecundated. If the spermatheca of an impregnated queen be examined under the microscope its contents will be found to contain many thousands of spermatozoa, the characteristic movements of which are very visible. The contents of the spermatheca of a virgin or drone-breeding queen, similarly examined, will be found a limpid fluid only without a trace of spermatozoa.

The fact that the eggs of an unimpregnated queen will hatch and produce drones may be easily verified, and is now undisputed. By depriving a colony of its queen late in the year, a young queen will be reared; and the drones having been killed long before, no impregnation can take place, yet the queen will infallibly lay eggs which hatch into drones; these eggs are laid indiscriminately in drone and worker cells, the bees bred in the latter being stunted in their growth. If now the spermatheca be examined, no spermatozoa will be found present. The same result will be found if, in the summer, the virgin queen be deprived of her wings and so made unable to fly.

Retarded impregnation.

If the impregnation of the queen be delayed beyond, as elsewhere stated, the twenty-first day of her life, she becomes incapable of receiving impregnation, and begins soon after to lay the eggs of drones, and produces no other kind of eggs during her life. This very curious and unexpected fact was discovered by Huber; and has been satisfactorily established by his very numerous and varied experiments, although its explanation is perhaps

attended with insuperable difficulties. The abdomen of a queen that is unimpregnated is much more slender than that of one which is completely fertile; but, on dissection, the ovaries are found expanded and full of ova.

Prolific workers.

One of the most remarkable facts concerning the generation of bees, is the existence occasionally of prolific workers, the discovery of which we owe to Reims. Although it was doubted by Bonnet, its reality has been fully confirmed by the researches of Huber and subsequent observers, and it explains what was before inexplicable—the production of eggs in hives absolutely destitute of a queen. It is also remarkable that the eggs thus produced are always those of drones, but this is explained by the fact that these fertile workers have not received, and, in fact, are unable to receive, impregnation from the drone. The origin of these abnormal egg-layers is accounted for from their having passed the larva state in cells contiguous to the royal ones, and from their having at an early period devoured some portion of the stimulating jelly which was destined for the nourishment of the royal brood, their ovaries thus receiving a partial development; or when a colony is deprived of its queen late in the autumn, and an attempt to raise a queen from some unknown cause has failed, a larva has sufficiently advanced to develop into a fertile worker.

Deposition of eggs.

As soon as a sufficient number of cells have been constructed, the queen begins to deposit her eggs. Unlike most insects the queen-bee deposits eggs ten or eleven months in the year in temperate climates, although it is probable this is not the case when the winter is much more severe than in Britain. Young queens ordinarily commence ovipositing thirty-six hours after impregnation. What power, if any, the queen has in determining the sex of her eggs is unknown, but, as already noticed, eggs that will produce workers or queens will always be found laid in worker cells, and those that will produce drones will also be found in their appropriate cells. A queen of a new swarm will rarely produce drones the first year; instinct, seemingly, teaching her they will not be required. In the early spring, if a clean empty piece of drone comb be put into the centre of the brood nest, the queen will usually fill it with drone eggs, and this circumstance is taken advantage of by scientific apiarians to secure a supply of drones for the impregnation of early hatched queens. When the eggs are about to hatch, the bees eagerly seek for that species of nourishment on which the larvæ are to be fed. This consists of pollen with a proportion of honey and water, which is partly digested in the stomach of the bees, and made to vary in its quality according to the age of the young. The egg of a bee is of a lengthened oval shape with a slight curvature and of a bluish white colour. It is hatched without requiring any particular attention on the part of the bees, except that a proper temperature be kept up, in which case three days are sufficient for the exclusion of the larva.

Metamorphosis of the larvæ.

This has the appearance of a small white worm without feet, which remains generally coiled up at the bottom of the cell. The bees feed it with great assiduity with the kind of chyle above described, and in every respect exhibit towards it the greatest care and attention. Hunter says a young bee might easily be brought up by any person who would be attentive to feed it. As it grows up it casts its cuticle like the larvæ of other insects. In the course of five or six days it has attained its full size, and nearly fills the cell in which it is lodged. It now ceases to eat, and the bees close up its cell with a covering of wax, or rather an admixture of wax and propolis, which they possess the art of amalgamating. During the next thirty-six hours the larva is engaged in spinning its cocoon, and in three days more it assumes the pupa state. It is now perfectly white, and every part of the future bee may be distinguished through its transparent covering. In the course of a week it tears asunder its investing membrane, and makes its way through the outer wall of its prison in its perfect form. Reckoning from the time that the egg is laid, it is only on the twenty-first day of its existence that this last metamorphosis is completed. No sooner has it thus emancipated itself than its guardians assemble round it, caress it with their tongues, and supply it plentifully with food. They clean out the cell which it had been occupying, leaving untouched, however, the greater part of the web, which thus serves to bind together still more firmly the sides of the comb. The colour of the bee when it quits the cell is a light grey.

First occupations of the workers.

For several days, sometimes a week or two after birth, the worker bees occupy themselves within the hive, not flying abroad during that time, their principal employment then being that of nurses; and many old observers thought them a different class altogether from the honey-gatherers and wax-makers.

Metamorphosis of the drone.

The metamorphosis of the male bee follows the same course, but requires four days longer for its completion, occupying twenty-five days from the time of the egg being laid to the attainment of the perfect state.

Metamorphosis of the queen.

When from the egg or young larva it is the intention of the bees to raise a queen, their attention is more incessantly bestowed upon it, the cell being enlarged as elsewhere described. It is supplied with a peculiar kind of food, which appears to be more stimulating than that of ordinary bees. It has not the same mawkish taste, and is evidently acid. It is furnished to the royal larva in greater quantities than can be consumed, so that a portion always remains behind in the cell after the transformation. As a proof that any worker egg or young larva not more than three days old may be made to produce a queen, the experimenter has only to supply to such an one a portion of royal jelly, and the nurses will enlarge its cell and continue so to feed it, when in due time a queen will be produced. The growth of the larva and the development of all its organs are very much accelerated by this treatment, so that in five days it is prepared to spin its web, and the bees enclose it by building up a wall at the mouth of its cell. The web is completed in twenty-four hours; two days and a half are spent in a state of inaction, and then the larva transforms itself into a pupa. It remains between four and five days in this state, and thus on the sixteenth day after the egg has been laid, the perfect insect is produced. When this change is about to take place, the bees gnaw away part of the wax covering of the cell till at last it becomes pellucid from its extreme thinness. This not only must facilitate the exit of the bee, but may possibly be useful in permitting the evaporation of the superabundant fluids.

Rivalship of the queens.

But the queen-bee, although perfectly formed, is not always at liberty to come out of her prison, for if the queen-mother be still in the hive waiting a favourable state of the weather to lead forth another swarm, the bees do not suffer the young queens to stir out; they even strengthen the covering of the cell by an additional coating of wax, perforating it with a small hole through which the prisoner can thrust out her tongue in order to be fed by those who guard her. The royal prisoners continually utter a kind of plaintive cry, called by bee-keepers "piping," and this appears to be answered by the mother queen. The modulations of this piping are said to vary. The motive of this proceeding on the part of the bees who guard them is to be found in the implacable hatred which the old queen bears against all those of her own sex, and which impels her to destroy without mercy all the young queens that come within her reach. The workers are on this account very solicitous to prevent her even approaching the royal cells while there is any prospect of a swarm being about

to issue. They establish themselves as a guard around these cells; and, forgetting their allegiance on this occasion, actually beat her off as often as she endeavours to come near them. If, on the other hand, the swarming season is over, or circumstances prevent any further swarms from being sent off, the bees do not interpose any obstacle to the fury of the old queen, which immediately begins the work of destruction, transfixing with her sting one after the other the whole of the royal brood, while they are yet confined in their cells. It is observed by Huber, that the royal larvæ construct only imperfect cocoons, open behind, and enveloping only the head, thorax, and first ring of the abdomen; and he conceives that the intention of Nature in this apparent imperfection is, that they may be exposed to the mortal sting of the queen, to whom they may be given up as a sacrifice.

When the old queen has taken her departure along with the first swarm, the young queens are liberated in succession, at intervals of a few days, in order to prevent their attacking and destroying one another, which would be the infallible consequence of their meeting. This exterminating warfare is prevented by the vigilance of the bees which guard them, so long as new swarms are expected to go off. When a young queen is liberated, she is, like others of her sex, anxious to get rid of her rivals, and even at that early age seeks to destroy her sisters, which are still confined in the other royal cells; but as often as she approaches them she is bit, pulled, and chased without ceremony by the sentinels. But when the season is too far advanced for swarming, or if two or more queens should happen to emerge at the same moment, they mutually seek each other and fight till one is killed, and the survivor is immediately received as the sovereign of the hive. The bees, far from seeking to prevent these battles, appear to excite the combatants against each other, surrounding and bringing them back to the charge when they are disposed to recede from each other, and when either of the queens shows a disposition to approach her antagonist, all the bees forming the cluster instantly give way to allow her full liberty for the attack. The first use which the conquering queen makes of her victory is to secure herself against fresh dangers by destroying all her future rivals in the royal cells; while the other bees, which are spectators of the carnage, share in the spoil, greedily devouring any food which may be found at the bottom of the cells, and even sucking the fluid from the abdomen of the pupæ before they toss out the carcases.

Swarming. We are now to direct our attention to the migrations of bees, by which new colonies similar to that which had originally peopled the parent hive are founded. The final causes of this phenomenon are sufficiently obvious, but it does not so clearly appear to what circumstances it is immediately owing. The increasing population of a hive probably occasions inconvenience from want of room; the increase of heat and the greater vitiation of the air become still more serious as the summer advances. The spring is, accordingly, the commencement of the swarming season. No swarming, indeed, will ever take place while the weather is cold, or until the hive is well stocked with eggs. The queen-bee, in consequence of the great number of eggs she has been laying, is now reduced to a more slender shape, and is well fitted for flight; her aversion for the royal brood, which she seems to foresee will in a short time become able to dispute the throne with her, and the vain attempts she makes to destroy them in the cradle, in which attempts she is invariably repelled by the bees who guard them, produce in her a constant restlessness and agitation which, as Huber represents it, rises to a degree of delirium. This frenzy, from whatever cause it may originate, is communicated to the workers; they may be seen hurrying to and fro in the combs with evident marks of impatience. The heat of the hive is increased by their tumultuous movements; it sometimes rises suddenly on these occasions from 92° to above 104°. A general buzz is heard throughout the hive. This stage of things occurs from time to time for some days before the swarm is actually on the wing; and the interval is occupied in making preparations for the approaching expedition; provisions are collected in greater quantity by the workers. Hunter killed several of those that came away, and found their crops full, while those that remained in the hive had their crops not nearly so.

Departure of the swarm. On the day on which the swarm quits the hive, few of the workers roam to any distance, but several are seen performing circles in the air round the hive. The noise is on a sudden hushed, and all the bees enter the hive; this silence announces their immediate departure. A few workers appear at the door, turn towards the hive, and striking with their wings, give, as it were, the signal for flight. All those which are to accompany the expedition rush towards the door, and issue forth with wonderful rapidity, rising in the air and hovering for some time, as if in order to wait for the assemblage of the whole troop; then, having selected a rallying point, generally on some tree or bush, some alight, being joined immediately by others until the whole number is collected in one mass of bees. It does not always happen that the queen is the first to alight or is with the cluster at all; but if she be not there the bees soon discover it and disperse in search of her—if they fail to find her they return to the parent hive. Thither the queen sometimes, from weakness or other causes, returns, and is immediately attended by the rest. But if the weather be fine, the expedition is only deferred for one or two days, and they again take their departure. If their return be owing to the loss of their queen, they remain a fortnight or longer before the attempt to migrate is renewed, and then the swarm is much larger than before, which renders it probable that they have waited for the queen that was to go off with the next swarm. Sometimes, when everything indicates an approaching emigration, the passage of a cloud across the sun will suspend all their operations, and the previous bustle gives place to a state of perfect calm. But, if the day be not far advanced, the breaking out of sunshine will renew the commotion, and determine the moment of actual flight.

The swarm having rested for some time on the first landing-place, and collected the whole of its numbers, soars again in the air, keeping in a close phalanx, and directing its course with great velocity to the spot which their guides had selected,—giving out, at the same time, a loud and acute-toned hum by the action of their wings.

Succession of swarms. The parent hive, thus deserted by its queen and a large proportion of its inhabitants, is busily occupied in repairing its loss. The bees which remain quietly pursue their labours; the young brood, soon arriving at maturity, quickly fill up every deficiency; and young queens, being allowed their liberty, one after the other, conduct in their turns new swarms, in the same manner as the first. The second swarm is not sent off till after the space of from five to ten days after the first. The following swarms succeed quicker to each other, but consist of smaller numbers than the earlier ones. If it happen that two queens are found in a swarm, either the swarm divides itself into two, and have separate destinations, or a single combat between the queens decides on which of them the empire is to devolve. Sometimes, indeed, they appear not to perceive each other, and the parties belonging to each construct separate combs within the same hive; but no sooner do these combs come in contact, and thus give occasion to the queens meeting each other, than a contest begins which terminates only by the death of one of the rival queens.

Successive swarms are sent off as long as the increase of population permits; and the number thus produced in a season depends on a variety of circumstances, such as the abundance of flowers, the warmth of the climate, and capacity of the hive. Bosc, while he was French consul in Carolina, found a stock of bees in the woods which had been robbed of its wax and honey by the negroes; he contrived to convey the bees in his hat to a hive in his garden. He obtained from this hive eleven swarms before the end of autumn; and these, again, gave him the same number of secondary swarms, so that by the end of the year he had twenty-two hives stocked from the one he had thus saved from destruction. In Britain a hive commonly sends off only two and sometimes three swarms in the course of the summer; and prudent apiarians will be satisfied with one swarm only, returning all subsequent ones to the parent hive, which would otherwise become very weak. When bar-frame hives are used, the issue of after-swarms is easily and surely prevented by destroying all queen-cells but one after the issue of the first swarm.

Massacre of the drones.

Very few drones accompany the new colonies, so that almost all those produced in the spring remain in the hive. But when the queens are impregnated, and no new swarms are about to take place, the workers, who had till then suffered them to live unmolested in the hive, are on a sudden seized with a deadly fury towards them, and a scene of carnage ensues. This usually happens in June, July, or August. They chase their unhappy victims in every quarter, till they seek a refuge at the bottom of the hive, where they collect in crowds, and are indiscriminately, and without a single exception, massacred by the working bees, who, with implacable fury, bite, maim, and throw them out of the hive. So great is their antipathy to all the race of drones, that they destroy, at the same time, the male eggs and larvæ, and tear open the cocoons of their pupæ, in order to devote them to one common destruction. This sacrifice of the males is not, however, the effect of a blind and indiscriminating instinct; for if a hive be deprived of its queen, the massacre does not take place, while the hottest persecution rages in all the surrounding hives. In this case the males are allowed to survive the winter.

Provision for the winter.

Having thus got rid of the useless mouths which consumed, without any advantage to the public, a large portion of their provisions, the bees spend the remainder of the summer in collecting stores of honey and of pollen for the ensuing winter. Their gleanings are now less abundant than in the spring, and require more labour in the search and collection. But at this season the leaves of many kinds of trees, which are covered in the morning with a saccharine fluid that exudes from them, furnish them with a species of nourishment, which, though of very inferior quality to the nectarial fluid, still contributes to their support. Fruit is also attacked by bees, after the cuticular covering has been broken through by birds or snails. They also find nutriment in the *honey-dew*, which is an excrementitious fluid deposited on the leaves of plants by certain species of aphides. Often, however, these resources fail, and the hive is threatened with famine. On these occasions the distressed bees frequently betake themselves to plunder; and if a weak or queenless hive can be discovered they begin a furious onset, which costs great numbers their lives. If the invaders should fail in their attempt to force the entrance they retreat, and are not pursued by those whom they have assailed; but if they succeed in making good the assault, the war continues to rage in the interior of the hive until one side finds itself beaten, in which case, should the conquerors be the invaders, the invaded will generally join their forces, and help their late enemies to carry off their plunder, and at once become members of the lately hostile hive.

Mutual depredations.

Length of life.

The life of a queen-bee will sometimes extend to three or four years, but her fertility decreases after her second breeding season. When absent from the hive on her matrimonial excursions she very often becomes a prey to a bird, and not seldom on her return mistakes her hive, when she is probably killed by the stranger bees, or by the queen on whose territory she has intruded. Drones seldom die a natural death; there is no evidence of the duration of the lives of individuals, but normally they are hatched about May and slaughtered by the workers in June, July, or August; should the hive be queenless, however, the workers do not harm the drones, and some will then live far into the winter or even to the following spring. The life of a worker is greatly dependent on the season of the year and the amount of labour performed. The modern method of introducing a fertile Ligurian queen (*Apis ligustica*) into a queenless stock of the common black bee (*Apis mellifica*), in order to obtain pure stocks of the former variety, has plainly demonstrated the short life of the worker bee. If the Ligurian queen be introduced in May, when bees are busy and work abundant, in from six to eight weeks thereafter scarcely a black bee will be found in the hive, although at the time of the introduction multitudes of young larvæ were present, which probably would not all be fully developed for nearly three weeks; therefore, in the season of hardest work, the inhabitants of the hive would seldom attain the age of six weeks. But if the experiment of the queen's introduction be deferred until October, then not until the following May will the black bees have become extinct. And it is a curious fact that if a hive be deprived of its queen in October (and none other supplied), then the workers, having no labour to perform either in replenishing stores or attending on the larvæ, will possibly in May be found still living, although somewhat reduced in numbers. Such a colony, however, generally becomes a victim to robbers when the activity of spring arrives, for a queenless stock rarely makes much defence of its stores. In fine winter days, when the sun shines brightly, numbers of bees are tempted abroad, which easily become benumbed by cold, fall to the ground, and die. Insectivorous birds also make victims of great numbers at such times, other insect food being scarce; so that, probably, in winter and early spring, more workers die from accident than by natural decay. The fecundity of the queen-bee is, however, adequate not only to repair these losses, but to multiply the population in a very high progression. *Apis ligustica* has the reputation of being more prolific than *A. mellifica*; and a young and vigorous queen will, in the fine weather of a warm May and June, deposit as many as 2000 eggs per day for several weeks in succession, and this fertility is of much longer continuance in America and other warm climates than in England. In England, eggs are deposited and young reared ten or eleven months in the year, when the colony is strong in numbers and well supplied with stores; but the increase in the cold months seldom equals the decrease by deaths.

Loss of the queen.

The loss of the queen is an event which has the most marked influence on the conduct of the workers. Although the queen is constantly an object of attention and of affection to the whole community, they are not immediately sensible of her absence when she is removed from the hive. The ordinary labours are continued without interruption, and it is not till a whole hour has elapsed that symptoms of uneasiness are manifested, and it is even then only partially displayed. The inquietude begins in one part of the hive, the workers become restless, abandon the young which they were feeding, run to and fro, and, by striking each other with their antennæ, communicate the alarming intelligence very quickly to their companions. The ferment soon extends to the whole community; the bees rush

precipitately out of the hive, and seek for their lost queen in every direction. This state of confusion continues for a day or two, after which tranquillity is again established; they return to their labours; and, selecting an egg, or one of the larvæ that is not more than three days old, they break down two of the contiguous cells, sacrificing the larvæ contained in them, and proceed to build up one royal cell from their ruins. They then supply the worm with the food necessary to promote its quick growth, and leaving untouched the rhomboidal bottom they raise around it a cylindrical enclosure. In three days the larva has grown to such a size as to require an extension of its lodging, and must inhabit a cell nearly of a pyramidal figure, and hanging perpendicularly. A new pyramidal tube is therefore constructed with the wax of the surrounding cells, which is soldered at right angles to the first, and the bees, working downwards, gradually contract its diameter from the base, which is very wide, to the point. In proportion as the worm grows, the bees labour in extending the cell, and bring food, which they place before its mouth and round its body, forming a kind of coiled zone around it. The worm, which can move only in a spiral direction, turns incessantly to take its food before its head; it insensibly descends, and at length arrives at the orifice of the cell. It then transforms itself into a pupa, is enclosed with a covering of wax, as before described, and, in the space of ten to sixteen days the original loss is thus repaired by the birth of a new queen. Schirach found that, if a number of bees be confined with even a single larva, which in the natural course would have become a worker bee, they immediately set about giving it the royal education above described, and thus raise it to the dignity of queen.

Rearing supernumerary queens. The discovery that queens may be reared at will has been confirmed by recent experiment, and is now largely taken advantage of by apiarians both in Europe and America, to facilitate the making of artificial swarms and otherwise increase the production of bees. By the aid of small frame hives called nucleus boxes, which only materially differ from the larger or mother hive by containing frames less in number and in size (generally three), a stock of fertile queens is kept on hand ready to supply any colony requiring a sovereign, or to exchange an old queen for a young one, or a Ligurian queen for an ordinary English one. An example of the method of rearing these queens is as follows:—A full comb containing young worker larvæ and eggs is taken, with all its attendant bees, and placed in the centre of the nucleus box, flanked on both sides by other combs containing honey. Sufficient young bees, which have not flown, are now added to cover well the brood comb, in order that proper heat may be kept up to mature the brood. As soon as the members of this small community find themselves without a queen, a dreadful uproar ensues; and, probably, should there be bees among them who know their way home, they will desert, but enough will usually remain to carry on the desired work; if not, more young bees must be added. These may be known by their fresher and greyer appearance. After a few hours the commotion will subside, and the bees will proceed to the construction of royal cells, and take proper care for the feeding and hatching of the larvæ selected for royal honours. Generally on the second day, the foundations of royal cells are perceptible, the number of these vary from one or two to as many as sixteen. In from ten to sixteen days, according to the age of selected eggs or larvæ, the young queens will arrive at maturity; and as the first at liberty will destroy the others if allowed, the apiarian in good time cuts out the sealed royal cells, which are distributed by grafting on other combs into newly-formed nuclei, or into such hives as require a queen. The young queens, on their emergence from the pupa state, are now each at the head of a colony, where they remain until they become fertile in the natural way, and are then ready for such purposes as they are required for.

Imported queens. In Switzerland, Italy, and Germany a large business is done in Ligurian queen-raising for export. Great numbers of those queens come to England and America in little wooden boxes, accompanied by sufficient workers to develop enough heat. The price in Italy varies, according to the season, from five francs in October to twelve francs in March; but few are raised until May, owing to the difficulty of their obtaining impregnation. To overcome this difficulty in the autumn some colonies are purposely kept queenless, whose drones remain in existence. **The advantages of supernumerary queens.** The advantage of having fertile queens at the bee-master's disposal is very great. When a swarm issues the young queen is not usually mature, and has to become impregnated. Should unfavourable weather ensue, a still further delay occurs; and the virgin queen, on her excursion, is liable to be lost or killed. Should no such accident occur, it may still be two or three weeks before ovipositing again commences, and this in the very height of the breeding season; while if the skilful bee-master, first taking the precaution to destroy any existing queen cells, can immediately, on the issue of the swarm, introduce the queen and her retinue from a nucleus hive, no time is lost, and probably 20,000 to 40,000 eggs will be deposited in the time that would otherwise have been lost. By this system of nucleus queen-rearing, it may be fairly calculated that the increase of population may be doubled. While the hive remains without a queen swarming can never take place, be the hive ever so crowded.

Queen combats. Huber has made the singular observation that two queens, however inveterate may be their mutual hostility, never actually destroy each other, and that when in the course of their contest they are placed in such a relative position that each has it in her power to strike a mortal blow on the other with its sting, they suddenly separate, and part with every appearance of being panic-struck. The final cause of the instinct that prompts this conduct is sufficiently obvious, as, without it, the hive would be altogether deprived of a queen.

Alien queens. Bees recognise the person of their own queen. If a stranger enter the hive, they seize and surround her until a ball of bees is formed one or two inches in diameter; in which imprisonment the unfortunate monarch is kept until death puts an end to her misery, for it is very remarkable the bees seldom sting a queen. A hive that has lost its queen may, however, by certain precautions be induced to accept a substitute. The most common way of attaining success in this operation is to imprison the stranger queen in a small cage of wire gauze or perforated zinc; this being suspended between two central combs or fixed upon one, the bees become accustomed to the odour and appearance of their new sovereign, and after the lapse of one or two days will readily accept her. If a supernumerary queen be introduced into the hive, she is laid hold of by the bees and presented to the reigning queen, while a ring is formed by the bees, who continue to be spectators, and even promoters of the combat, in which one or other of the queens is destined to perish. Schirach and Reims had imagined that, in these circumstances, the stranger met her death from the hands of the working bees, but this mistake has been corrected by Huber, who gives the account above stated.

Effects of mutilations. We have next to relate the results of experiments of a more cruel kind, which illustrate several points in the physiology of these insects. The amputation of the four wings of the queen did not interfere with her laying eggs, and the workers did not show her the less attention on account of her being thus mutilated. Of course, if the

operation be performed before she is impregnated, she remains barren, since it is necessary for the sexual congress that she should fly out of the hive. The amputation of a single antenna appeared to be productive of no bad consequence of any kind; but the removal of both the antennæ was followed by singular effects. The queen which had suffered this operation ran about in apparent confusion, dropping her eggs at random, and was incapable of directing her tongue with precision to the food that was offered her. At times she appeared desirous of escaping from the hive; and when this was prevented, she returned in a state of delirium, was indifferent to the caresses of the workers, and received another similarly mutilated queen that was presented to her without the least symptom of dislike. The workers, on the other hand, received the stranger queen with great respect, although the first still remained in the hive. A third queen, not mutilated, was next introduced; she was very ill received and immediately detained and kept a close prisoner, being evidently regarded as an intruder. When the queen deprived of her antennæ was allowed to quit the hive, she was followed by none of the workers, and was abandoned to her fate.

Enemies of bees. The wasp and the hornet have long been known as the determined enemies of the bee, committing great ravages among these weaker insects; they attack them individually, but oftener commit their aggressions in large armies, on which occasions numbers perish on both sides. In some parts of America wasps have multiplied to so great a degree as to render it impossible to rear bees. Among quadrupeds the ant-eater occasionally devours them. The bear and the badger overturn the hives, and plunder their contents. Rats and mice are very formidable enemies, as they attack the bees at all seasons, and especially during the torpid state of the insects, when they are incapable of revenging the aggression. The woodpecker may succeed in breaking through the hive, and then speedily destroys all its inhabitants; the swallow, the sparrow, the titmouse, the cuckoo, the *Merops apiaster*, or bee-eater, and poultry of every kind, prey upon them separately. According to Bosc, they are also food for the shrikes and for the *Falco apivorus*. Lizards watch for them, and seize them as they alight near the hive. Toads occasionally devour them. They are in some danger from the larger kinds of spiders, and of *Libellulæ*, as also from the *Philanthus apivorus* of Fabricius. But the most insidious and destructive enemies of these insects are moths, two species of which, *Galleria mellonella* and *Achroia grisella*, insinuate themselves into the hive, and deposit their eggs on the combs in such numbers, that the hive is soon overrun with the larvæ, the combs destroyed, and the bees eventually forced to vacate the hive. In America and in Italy these moths are much more troublesome than in England. On the Continent of Europe bees are also troubled with a parasite called the bee-louse (*Braula cæca*), sometimes as many as 50 or 100 being found on a single bee, and as they live by suction they are great pests. This insect is not frequently found in England except accompanying imported Ligurian bees.

Diseases of bees. Bees are subject to few diseases, but these few are sometimes very fatal. Dysentery occasionally commits great havoc in a hive, and is usually caused by the neglect of sanitary measures, by close confinement, want of ventilation, and damp. Dysentery is indicated by the appearance of the excrement within the hive, which the bees in a healthy state are particularly careful to exclude. It is often induced by the bees being forced into undue excitement in cold, ungenial weather. The disease known generally by the name of "foul brood" is the most fatal of all; it is highly contagious,—the infection from its presence remaining in the hives, combs, and honey long after the bees are exterminated. Dysentery is a disease of the perfect insects only. Foul brood is confined to the larvæ, which, having grown to near maturity, die and putrefy after being sealed over by the bees. The workers seem totally unable to remove the foul mass which thus remains to spread infection all around. The seed of the disease is believed to lie in the presence of the spores of a microscopical fungus (*Micrococcus*), and long scientific discussions and experiments have been made on the Continent to demonstrate this, particularly by Drs Preusz and Schönfeld. The devastation caused in apiaries by this disease is sometimes fearful. Dzierzon relates that, in 1848, he had nearly the whole of his colonies destroyed by it, more than 500 being destroyed, and only 10 escaping. Quinby also, in America, has lost as many as 100 stocks in a single year by this pestilence. And when once fully developed a total destruction of all hives and combs infected appears to be the only way of eradicating it. Honey from a foul brood hive will carry the germs of the disease to any bees which may consume it. The presence of this disease may be detected by the foul smell emanating from the hive, and from the circumstance of many cells remaining covered longer than naturally occurs when there are living pupæ within them.

Pasturage. In the management of bees a great deal must, of course, depend on supplying them with an abundant pasture. A rich corn country is well known to be to them as a barren desert during a great portion of the year. Hence the judicious practice of shifting them from place to place according to the circumstances of the season. It was the advice of Celsus that, after the vernal pastures were consumed, bees should be transported to places abounding with autumnal flowers; and in accordance with that advice they were in ancient times annually carried from Achaia to Attica, and from Eubœa and the islands of the Cyclades to Scyrus. In Sicily, also, they were brought to Hybla from other parts of the island. So also in Scotland so soon as the "bright consummate flowers" of summer are on the wane, the people of the Lowlands despatch their hives in cart-loads to the blooming heather of the mountain pastures, where a never-ending paradise of sweets is spread before them. It is, indeed, to be regretted that our moorlands are not more utilized for this object than they are. The very air of the Highland hills is often redolent with rich perfume, giving earnest of a bountiful harvest; only a solitary bee is seen here and there, labouring with wearied wing among the inexhaustible stores of nature, and scarcely able to regain with its burden its lonely shieling in the distant vale. Considering the poverty of the peasantry, and their frequent want of occupation, it is to be lamented that so easy and pleasant a source of emolument should be so much neglected by them. In consequence of this neglect a large sum is paid every year to foreign nations for articles that could be raised at home, in every respect superior, with very little outlay either of labour or of capital.

We learn from Pliny that the practice of removing bees from place to place was frequent in the Roman territories. "As soon," he says, "as the spring food for bees has failed in the valleys near our towns, the hives of bees are put into boats, and carried up against the stream of the river in the night, in search of better pasture. The bees go out in the morning in quest of provisions, and return regularly to their hives in the boats, with the stores they have collected. This method is continued till the sinking of the boats to a certain depth in the water shows that the hives are sufficiently full; and they are then carried back to their former homes, where their honey is taken out of them." And this is still the practice of the Italians who live near the banks of the Po, the river which Pliny instanced particularly in the passage above quoted.

M. Maillet relates, in his description of Egypt, that, "in spite of the ignorance and rusticity which have got possession of that country, there yet remain in it several footprints of the industry and skill of the ancient Egyptians. One of their most admirable contrivances is sending their bees annually into distant countries, in order to procure sustenance, at a time when they could not find any at home, and afterwards bringing them back,—like shepherds who should travel with their flock, and make them feed as they go. It was observed by the ancient inhabitants of Lower Egypt, that all plants blossomed, and the fruits of the earth ripened, above six weeks earlier in Upper Egypt than with them. They found that the same law applied to their bees; and the means they then made use of to enable these usefully industrious insects to reap advantage from the more forward state of nature there, were exactly the same as are now practised for the like purpose in that country. About the end of October, all such inhabitants of Lower Egypt as have hives of bees, embark them on the Nile, and convey them up that river into Upper Egypt, observing to time the journey so that they arrive there just when the inundation is withdrawn, the lands have been sown, and the flowers begin to bud. The hives thus sent are marked and numbered by their respective owners, and placed pyramidally in boats prepared for the purpose. After they have remained some days at their furthest station, and are supposed to have gathered all the wax and honey they could find in the fields within two or three leagues around, their conductors convey them in the same boats two or three leagues lower down, and there leave the laborious insects as long time as is necessary for them to collect all the riches of this spot. Thus the nearer they come to the place of their more permanent abode, they find the productions of the earth, and the plants which afford them food, forward in proportion. In fine, about the beginning of February, after having travelled through the whole length of Egypt, gathering all the rich produce of the delightful banks of the Nile, they arrive at the mouth of that river, towards the ocean, from whence they originally set out. They are now returned to their several homes, great care being taken to keep an exact register of every district from which the hives were sent in the beginning of the season, their numbers, the names of the persons who sent them, and likewise of the mark or number of the boat in which they were placed."

In many parts of France floating bee-houses are also common; there are on board one barge three to five score of bee-hives, well defended from the inclemency of an accidental storm. The owners allow their barges to float gently down the river, the bees continually choosing their flowery pasture along the banks of the stream, and thus a single floating bee-house yields the proprietor a considerable income. They have also a method of transporting their bees by land which is well worth imitation. Those hives being selected whose combs are firm and not likely to be broken by jolting, thirty to forty of them are carefully packed in tiers in a cart, which proceeds slowly on its travels. If the season be sultry, they journey only at night, the hives being covered up with a cloth. On arriving in a suitable locality the hives are taken out of the cart, set upon the ground, and the bees go forth in search of food. In the evening, as soon as they are all returned, the hives are shut up, and being placed again in the cart they proceed on their journey. When the caravan has arrived at its destination, the colonies are distributed in the gardens or fields adjacent to the houses of the different peasants, who, for a very small remuneration, undertake to look after them.

Bee keeping in different countries.

On the continents of Europe and America bee-keeping is carried on in a much larger and more scientific manner than in the United Kingdom, where the cottagers still, in the greater majority of instances, use only the ancient straw skep or hive, and know no other method of depriving the colonies of their stores than the barbarous and wasteful practice of smothering them with brimstone. In Russia the province of Pultowa boasts of 500,000, and Ekaterinoslaw has 400,000 hives. In Western Russia the industry chiefly flourishes in the province of Kowno, where the Tchmude tribe are almost wholly engaged in bee-keeping: and in Eastern Russia the Finnic tribe are enthusiastic apiarians. In Siberia bee-keeping is mostly carried on about the Altai mountains, and in Caucasia by the Meretinzes and Grusinians. In Southern Russia artificial hives are used, while in North Russia the bees are kept in a natural manner in the forests. The principal reasons why bee-culture is so industriously carried on in Russia are, first, because the peasants use honey instead of sugar, and, secondly, because wax tapers, to the value of 1,200,000 roubles, are required for the churches. Mr Buschen states that the quantity of honey annually produced in European Russia is 600,000 to 700,000 ℔. In Hungary and Germany apiaries of 2000 to 5000 colonies are said to be not infrequent; and great numbers are in the autumn often found congregated together on the heaths. In 1873 the aggregate number of stocks in Germany, including Hanover and Hesse Cassel, was found to be 1,453,764 stocks; Bavaria alone had 338,897. The German Government encourages bee culture in every possible manner; teachers, paid by the state, travel through the rural districts teaching the best methods of cultivation; and all schoolmasters, before receiving their diplomas, have to pass an examination in this subject. Bee-clubs in the villages are common, money for prizes and expenses being in part supplied by the Government. The result of this fostering care is that Germany produces many skilful apiarians, who contribute greatly to our knowledge of the science. In the United States bee-farming is largely carried on as a distinct trade, every scientific appliance being eagerly brought into use. The country also seems to be particularly productive of honey-secreting flowers, and consequently large harvests are gathered. In 1874 one bee-farm alone, that of Mr Harbison, situated in San Diego county, California, produced 150,000 ℔ of honey, of a market value of $30,000, from 2000 stocks of bees. The honey-bee of both varieties (*Apis mellifica* and *A. ligustica*) has also been introduced into South Africa and New Zealand, where it flourishes amazingly.

Apiaries and Hives.

Apiaries and hives.

Having thus given at considerable length the natural history of the bee-hive, we proceed to describe the most approved hives, &c., in use in a well-managed apiary. Greater attention to this useful appendage to the cottage would not only be productive of commercial advantage, but would tend to improve the condition of the peasantry. It is not generally known, indeed, what profitable results may be obtained, at a trifling expense of time and labour, from bee-keeeping. Even supposing the first cost of a swarm to be one guinea, which is a high price, the cottager, with proper care and management, will clear, in five years, a net profit of nearly £60, and have besides, at the end of that period, ten good stocks of bees in his garden.

The principal objects to be considered in the construction and management of an apiary, are, first, to secure the prosperity and multiplication of the colonies, and then to increase the amount of their productive labour, and to obtain their products with facility and with the least possible detriment to the stock. The apiary should afford to the bees shelter against moisture and the extremes of heat and of cold, and especially against sudden vicissitudes of temperature. The hives should render every facility for constructing the combs and rearing the young; they should allow of every part of the combs being occasionally inspected, and of their being removed when necessary; and, while due attention is paid to economy, they should be made of materials that will insure durability. Much ingenuity has been displayed by different apiarians in the construction of hives to unite in the greatest possible degree all these advantages; but there is still great room for improvement on the hives that are in common use.

While some cultivators of bees have been chiefly anxious to promote their multiplication, and prevent the escape of the swarms in the natural way by procuring what are termed "artificial swarms," which is effected by various means, others have taken into consideration only the

abundance of the products which they yield, and the best way of extracting them from the hive, without showing any particular solicitude as to the preservation of the bees themselves; still another class of apiarians have had more particularly in view the prosecution of researches in the natural history and economy of bees. The hive invented by Huber was in his time a great advance for the purpose last named. He gave it the name of "ruche en livre ou en feuillets" from its opening and shutting somewhat in the manner of the leaves of a book. It had, however, many inconveniences which are remedied in some hives of more modern construction, and Huber's leaf-hive is now rarely used, although it may claim the distinction of having been the first of the frame hives which are now, with many modifications, generally acknowledged to be the only ones capable of giving the maximum of prosperity to the bees and producing a large honey harvest, combined with affording facilities for observation and manipulation. The old cylindrical straw skep or hive is still generally used among the cottagers of England, although abandoned in many other countries. While very excellent for warmth and ventilation, it has the disadvantage that its interior is inaccessible for information; and the fixity of its combs precludes many manipulations which the skilful apiarian is called upon to perform. This was well known to the ancients, who, to remedy it, fitted the crowns of their hives with movable wooden bars, from which the bees built their combs, but still they were attached by their sides to the hive and required to be cut away before they could be removed,—these operations greatly disturbing the bees. In 1851, Dzierzon in Germany, and Langstroth in America, two of the most skilful apiarians of the present day, simultaneously designed or invented the bar-frame hive, the principle of which, with many varieties of detail, is found in all the best hives now in use. A well-known English example of this kind of hive is the "Woodbury" (fig. 4), named after its designer, Mr Woodbury of Exeter. This consists of a square wooden box, $14\frac{1}{2}$ inches in diameter (inside measure), and 9 inches deep, covered by a top or crown-board either loose or lightly screwed down. This board has a circular hole in the centre, $2\frac{1}{2}$ inches in diameter, for feeding purposes, and when not in use is covered with perforated zinc or a block of wood. The floor-board is 18 inches square, with an entrance cut in it forming a channel about 4 inches wide and $\frac{3}{8}$ths of an inch deep. At the part where the front of the hive crosses it gradually slopes upwards inside the hive. An alighting-board for the bees is fixed to the front of the floor-board opposite the entrance, and projects 3 or 4 inches; a wooden ridge-roof covers all. The interior of the hive is fitted with ten frames; they are made of light lath, about $\frac{7}{8}$ths of an inch wide, the top bars being $\frac{3}{8}$ths and the sides and bottom rails $\frac{5}{16}$ths of an inch in thickness respectively. The top bars are $15\frac{1}{4}$ inches in length, and project into notches cut into rabbets at the back and front of the hive to receive them. The rabbets are $\frac{5}{8}$ths of an inch deep, and the notches in them are of the same depth, so that the projections in the bars rest flush in them, leaving a space of $\frac{3}{8}$ths clear above the frames, over which the bees can travel. The ten frames occupy equal portions of the interior space; if this be divided into ten equal divisions, the centre of each will be exactly the point at which the centre of each bar frame should rest; these points will be $1\frac{9}{20}$ inches apart. In these frames it is intended that the bees shall build their combs; and when they have done so, any frame may be quietly lifted out of the hive with all the bees upon it, whether for examination or for division of the stock for an artificial swarm. To induce the bees to build straight in the frames a thin strip of comb is usually attached to the underside of the top bar, or a thin line of molten wax poured down the centre of the bar will answer the purpose, as the bees will follow the guide thus laid. For the purpose of providing storage-room for honey an upper storey, called a "super," is added to the hive, of the same diameter but of less height, 3 to 5 inches usually sufficing, as when filled it may be taken off and an empty one substituted. Before a super be placed in position, the crown-board should be removed, and a thin board, called an "adapter," substituted; this, in place of the round central hole, has near each side a long aperature, $\frac{3}{16}$ths of an inch wide, which gives passage to the workers, but not to the queen and drones—the latter being useless there, and it being desirable the queen should not oviposit in the super.

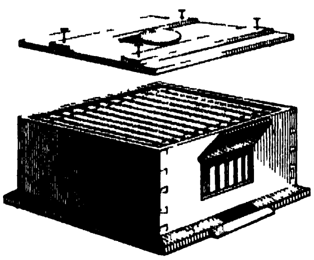

FIG. 4 —The Woodbury Frame Hive

Elegant supers are made of glass globes, or propagating glasses, which the bees will readily use if enticed into them by a few pieces of clean white comb.

Many improvements have been made on the Woodbury hive, tending still further to the comfort and well-being of the bees, as well as to the furtherance of scientific study; and, perhaps, the hive that may be said to combine most of these advantages is one designed by Mr Frank Cheshire, and known as the "Cheshire Hive" (figs. 5 and 6).

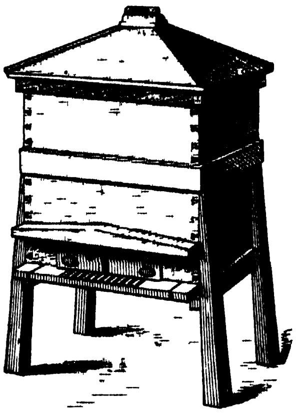

FIG. 5.—The Cheshire Frame Hive.

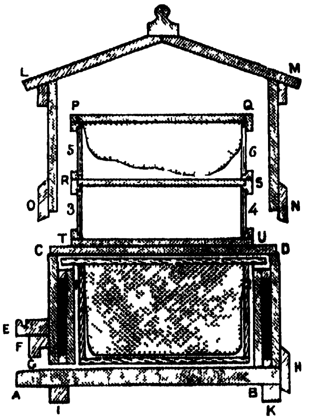

FIG. 6.—Section of Cheshire Hive.

To afford the bees the maximum of comfort and to economize their heat, the walls of this hive are made double, enclosing an air space. The Woodbury frames are used, but rest on the thin edge of a strip of zinc within the hive at the back and front, which prevents the bees fixing them with propolis. The floor-board is constructed to slide in a groove beneath the hive, and the entrance can be enlarged or diminished at pleasure by a pair of sliding-shutters; the hive is complete with stand and roof, and altogether leaves little to be desired.

The adoption of frame hives has greatly facilitated the scientific study of the insects' habits, the artificial multiplication of colonies, and the appropriation of their surplus stores without injury to the bees. It is quite a secondary consideration what size or pattern of frame is used, or how the frames are suspended in the hive, provided the principle of movable frames be adopted; and although much ingenuity has been exercised by scientific men to design a hive embracing every possible advantage regardless of cost, the roughest timber and coarsest workmanship will give as good results as the most elaborate. Frame hives are exceedingly well calculated for procuring artificial

swarms. They allow us to judge by inspection whether the population be sufficient to admit of division, if the brood be of the proper age, if drones exist or are ready to be produced for impregnating the young queens,—all of which circumstances are material to the success of the operation. Wooden hives are generally made square, but not invariably so. The "Stewarton hive" (fig. 7), largely and successfully used in Scotland, is octagonal, and the "Quinby hive" of America is much deeper from back to front than it is wide. The Stewarton is not properly a frame, but a bar-hive, although frames are sometimes fitted to it. It usually consists of three octagon breeding-boxes, 14 inches in diameter by 6 inches deep, each furnished with nine bars placed equidistant, the spaces between being occupied by movable slides of wood working in grooves in the bars. The hive has shuttered windows back and front, handles to lift, and hooks to weigh with, as well as little buttons to prevent displacement; each breeding-box has an entrance-way 4 inches wide and half an inch high, with a sliding door to close it wholly or partially. There are also two supers or honey boxes, the same diameter as the stock boxes, but only 4 inches deep; these are furnished with wider bars, seven in number, and a floor-board completes the whole, which, being made of but ½ inch wood, requires protection from the weather.

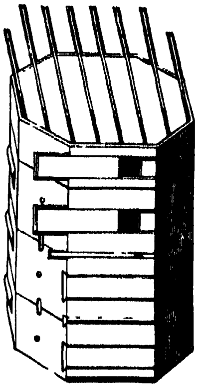

Fig. 7.—The Stewarton Hive.

For those persons who are unable to handle bees with impunity, but are yet desirous of studying their economy, a glass covered observatory hive has been deemed a necessity. Several have been designed for this purpose, but none of them have been found to be a healthy abode for the bees,—glass being a cold and ungenial material, on which the moisture of the hive condenses during the winter to the detriment of health of the inhabitants. In the summer, however, bees may be kept in a glass hive without great loss, although with no gain; such a hive may be constructed of a double sash, thickly glazed back and front, of just sufficient width for one comb only and space to allow the bees free passage over both sides of the comb. A very excellent hive in English use is that known as the "Woodbury unicomb," which is so constructed that six frames may be taken out of an ordinary hive, and hung up in a double perpendicular row between the two sashes, permitting their return in the autumn to their original hive. Egress and ingress is given to the bees by a tunnelled channel to the centre of the hive on the floor line; and by means of a turn-table the hive may be revolved to bring both sides under alternate observation, together with all its inhabitants and their works. The common straw hive, or skep, of the cottagers is too well known to require description, and although it is greatly inferior to frame hives, it will doubtless long retain a place from its easy make and little cost. A great improvement now generally in use is the adoption of a round hole in the centre of the crown, about 2½ inches in diameter, which will permit the bees access to the super, and afford facilities to the bee-master for feeding his stock. The capacity of these hives should be about a bushel, when the apiary is situated in a good honey locality.

Honey-extractors. To a German apiarian we are indebted for the invention of a machine called the honey-extractor, which, with some subsequent improvements, forms a most important aid in large apiaries to increase the yield of honey. By this appliance the frames of full honeycomb are in a few seconds emptied of their contents without injury to the combs, which are ready at once to be returned to the hive to be refilled, thus saving to the bees great labour in comb-building, and enabling them to take the utmost advantage of a favourable honey-time, which usually is but short. Honey is saved too, which the bees eat in comb-building; for it has been calculated that bees consume 20 lb of honey in producing 1 lb of wax. There are various patterns of the machine, but the principle of all may be said to be the same, that of centrifugal force. The apparatus consists of a cylindrical metal reservoir, with a tap at the bottom; and within is contained a perpendicular quadrangle frame, two sides of which are covered with wire-netting, and against these the full honeycombs, with their cells previously uncapped, are placed. This framework is then set revolving by means of a handle and cog-wheels, or other motive power, when the honey is flung out against the sides of the cylinder, and the combs completely emptied to be returned to the bees to clean and refill. The loss of this honey, and the excitement caused by the cleaning the wet combs, seem to induce the bees to work their hardest to replace their stores; and with a strong colony an enormous amount of honey is obtainable in a good locality and season. It has been recorded that one stock in America gathered 600 lb in a single season, and harvests of 200 lb and 300 lb are not uncommon there.

Bee-Keeping.

We shall now give a short exposition of the modern, humane, and scientific system of bee-keeping, which is probably destined at no distant day to supersede the ignorance and cruelty of past ages.

Stocking a frame hive. A description has already been given of examples of the best movable bar and frame hives, and the system they represent should alone be adopted, *i.e.*, every comb in the hives should be movable and interchangeable. In stocking these it is usual, first, to hive the swarm in an old-fashioned straw skep; and in the evening, after all the bees are quietly settled, suddenly to shake them down against the entrance of the hive or on the top of the frames, when the astonished insects will immediately take refuge in their future home. Should continuous bad weather occur after hiving a swarm, the bees must be fed, for, as they have as yet no stores, they will otherwise starve.

Feeding bees. For feeding bees a multitude of appliances have been invented, but they may all give place to a common wide mouth pickle bottle; this is filled with syrup, the mouth tied over with a double fold of net, and placed inverted on a piece of perforated zinc or vulcanite over the feeding-hole of the crown-board of the hive. The supply can be regulated to the bees by the number and size of the holes through which they are allowed to suck. In cold weather when much moisture would be hurtful in the hive, barley-sugar may be advantageously used as a substitute for syrup. The former is made by boiling, for ten minutes, 2 lb of loaf-sugar in a pint of water, a little vinegar being added to prevent crystallization. The prosperity and profit of an apiary in a great measure depend on judicious feeding. It is bad economy to stint the bees in food. In the early spring slow and continuous feeding (a few ounces of syrup each day) will stimulate the queen to oviposit, by which means the stocks are rapidly strengthened and throw off early swarms. Upon the emergence of these, if a young fertile queen be immediately supplied, the hive is ready again to swarm in a remarkably short time. It is a singular fact that if stimulating feeding has been for some time pursued, and the supply be intermitted and nothing coming in from the fields, the bees will destroy all the young larvæ and eggs, instinct seeming to teach the wise insects that the calls on the resources of the colony in the way of food for the young will be more than it can bear.

Water. An abundant supply of water is essential to the healthy condition of bees. They consume a large quantity, and often stop to drink at the edge of stagnant pools, and seem even to prefer putrid and urinous waters to purer streams, as if their saline and pungent qualities were grateful to them.

Honey harvest. Where the bee-keeper has the use of a honey-extractor, and a large produce of honey is his desideratum, the combs can be emptied as fast as they are filled; and at the close of the season the bees may be deprived of the whole of their honey if syrup be supplied to them in its place. This is of much less value, and answers every purpose for winter stores. No hive should be trusted to the exigencies of winter with a less weight of sealed comb than 15 lb. Honey may also be gathered into supers; and the bees in good seasons will readily build their combs there, but should be enticed to do so with a few pieces of nice white decoy-comb placed within. The management of the Stewarton hives may be described as follows:—Two of the breeding-boxes having had their bars furnished with guide-comb, are lashed together, the sliding-door of the upper one run in and the slides of the lower withdrawn, when the two boxes become virtually one; a prime swarm of bees is introduced, and eight or ten days thereafter, another prime swarm being hived in the third breeding-box, it is placed under the other two. The lower of the two first boxes, now the central, has its door run in and the slides of the lower withdrawn. The second swarm of bees will soon run up and fraternise with the others; and the next morning the lowermost box may be removed, and the entrance opened of the one above. The space provided by the two boxes will be found ample for breeding; and when full, the strong stock formed by the double swarm will soon be glad to occupy the super then to be added, to which communication should be afforded by withdrawing the outer slide on each side only. Should the season prove favourable the super will soon be filled, and when nearly so another should be placed on the top, and the first may be removed as soon as the honey cells are sealed over. All supers must be warmly wrapped up or padded, or the bees will be found reluctant to occupy them.

By the judicious management of supers, and the use of the honey-extractor, swarming may be in a great measure controlled; for if many swarms issue, the result must be that little honey will be gathered; all the energies of the reduced population being exerted to procure food for and attend to the young. A super put on the hive before the bees have made preparations for swarming by the construction of queen cells, &c., will generally prevent swarming, but not invariably. The bee-keeper must, therefore, decide whether he prefers an increase of his stocks or a large honey harvest, and manage his bees accordingly.

Artificial swarming. It often happens that bees give every indication of an intention to swarm, and cluster idly outside the hive in large numbers for days or even weeks before they really emigrate,—all this time keeping their owner in suspense; and possibly the swarm comes off at last without being observed. This is very tantalising, but may all be prevented by means of artificial swarming, the mode of proceeding for which varies according to the kind of hive in use. Considering, first, straw skeps, the common hive of the country, the operation to be pursued is known as "driving." This is not new, having been described by Dr. Warder in the last century. The mode usually adopted is as follows:—Towards noon, on a fine day, when many of the bees are abroad, inject at the hive's entrance a puff or two of tobacco smoke, and with the hands give a smart smack on each side. The effect is that the whole of the inhabitants are struck with extreme terror; and after, perhaps, an alarmed sally to the entrance, every bee rushes to the cells to fill itself with honey. Allowing two or three minutes for them to effect their purpose, the hive is boldly inverted and an empty hive of the same size placed on it mouth to mouth. A long towel is now bound round the junction to confine the bees, and the operator, with two sticks or the palms of his hands, keeps up a continuous smart rapping on the sides of the full hive, and after a few minutes the bees will all stream up into the empty hive, generally not more than fifteen minutes having elapsed before the first hive is denuded of its inhabitants. It should now be placed on the stand of some other strong stock (previously removed), whose returning bees will form a population to nurse the young and rear a queen if one be not supplied by the apiarian. If the swarm is to be at once sent away to a distance exceeding $1\frac{1}{2}$ miles, the hive may be returned to its old stand, and so be peopled by the remainder of its old inhabitants who were at work. But if the swarm is to remain near, it should be placed on the old stand, as the bees, on their next flight, will return to the locality they know so well. "Driving" should also be pursued in the autumn, when it is desired to appropriate the honey of the hive. The driven bees should then be added to another stock, which they will advantageously strengthen. Where frame hives are in use, the following method may be adopted:—First, lift out the frames and search until the queen be found, when she, with the frame she is on, must be placed in the centre of a new hive, and be flanked on both sides by another comb as full of sealed brood as can be obtained. Fill up both hives with new frames furnished with empty combs, or guide-combs only if the former be not available, and shake into (or before the entrance of) the hive where the queen is sufficient bees to form a large swarm. Many will fly back to their old home, but all the young bees will remain. This hive should then be removed to some distance and the old one replaced. If the swarm is to be sent to a distance, the bees may be simply shaken off the combs into (or in front of) a new hive (taking care the queen is with them), which should be temporarily placed on the spot where the old one has just stood. The bees will enter it, and when all is quiet it should be removed and the old one reinstated. The bees that return from the fields will form a population for the domicile which they will find in the familiar place. Before in any manner operating on bees, it is advisable to puff a little smoke into the hive. This alarms them and causes them to fill their honey-pouches, and a bee in this state never volunteers an attack; but it is always prudent to cover one's face and hands, as home-returning bees are sometimes inclined to resent the disturbance to their family. India-rubber gloves, with gauntlets and veil of leno, will afford ample protection; the latter should be a simple bag, open at top and bottom, but with half a yard of elastic sewn in the top, through which should be passed the crown of a broad-brimmed hat; the coat should be buttoned over the lower part. Bee-keepers who meddle much with their bees soon become accustomed to stinging and do not suffer much. Experiments have been made to ascertain the number of stings required to inoculate the blood, and it has been stated that about thirty, at the rate of three or four a day, will suffice, after which the effect of the bee-poison is trivial. Persons unaccustomed to the poison, however, often suffer severely.

We conclude by observing that the honey-bee (*Apis mellifica*) is supposed to be of Asiatic origin. It was imported from Europe to America, where it is now found wild in great numbers, and at a vast distance from human habitations. An excellent treatise, *The Honey-Bee, its Natural History, Physiology, and Management*, was published in 1827 by Dr Edward Bevan. It contains some of the best practical remarks on the subject that are anywhere to be met with, and gives a fair account of the labours of the author's predecessors, Reaumur, Hunter,

Huber, Keys, Vicat, and Dunbar. The Rev. L. L. Langstroth, of New York, has also written a very excellent volume on *The Hive and Honey-Bee*. To Pastor Dzierzon, the Baron von Berlepsch, and Von Siebold of Germany, we are indebted for many accurate and valuable observations on physiology and hive management; and a *Manual of Bee-keeping*, written in 1875 by Mr. John Hunter, secretary of the British Beekeepers' Association, contains much practical information on scientific and profitable bee-keeping. We may add that the above association, established in 1874 under the presidency of Sir John Lubbock, is the first vigorous effort made in England to extend and improve this neglected although valuable branch of rural economy. (J. H.)

BEECH, a well-known tree, the *Fagus sylvatica*. For the cultivation and properties of it see ARBORICULTURE, vol. ii. p. 317. The name beech is from the Anglo-Saxon *boc*, *bece*, or *beoce* (Ger. *Buche*, Swedish, *bok*), words meaning at once a book and a beech-tree. The connection of the beech with the graphic arts is supposed to have originated in the fact that the ancient Runic tablets were formed of thin boards of beech-wood. "The origin of the word," says Prior (*Popular Names of British Plants*), "is identical with that of the Sanskrit *bôkô*, letter, *bôkôs*, writings; and this correspondence of the Indian and our own is interesting as evidence of two things, viz., that the Brahmins had the art of writing before they detached themselves from the common stock of the Indo-European race in Upper Asia, and that we and other Germans have received alphabetic signs from the East by a northern route, and not by the Mediterranean." Beech-mast, the fruit of the beech-tree, was formerly known in England as buck; and the county of Buckingham is so named from its fame as a beech-growing country. Buckwheat (*Buchenweizen*) derives its name from the similarity of its angular seeds to beech-mast. The generic name *Fagus* is derived from φάγω, to eat; but the φηγός of Theophrastus was probably the sweet chestnut (*æsculus*) of the Romans. Beech-mast has been used as food in times of distress and famine; and in autumn it yields an abundant supply of food to park-deer and other game, and to pigs, which are turned into beech-woods in order to utilise the fallen mast. In France it is used for feeding pheasants and domestic poultry. Well-ripened beech-mast yields from 17 to 20 per cent. of a non-drying oil, suitable for illumination, and said to be used in some parts of France and other Continental countries in cooking, and as a substitute for butter.

BEECHEY, FREDERICK WILLIAM, a distinguished naval officer and navigator, son of Sir William Beechey, R.A., was born in London, in 1796. In 1806, at the age of ten, he entered the navy, and was for several years engaged in active service during the wars with France and America. In 1818 he served under Franklin in Buchan's Arctic expedition, of which at a later period he published a narrative; and in the following year he accompanied Parry in the "Hecla." In 1821 he took part in the survey of the Mediterranean coast, under the direction of Captain, afterwards Admiral, Smyth. He and his brother, H. W. Beechey, made an overland survey of the north coast of Africa, of which a full and valuable account was published in 1827. In 1825 he was appointed to the "Blossom," which was intended to explore Behring's Straits in concert with Franklin and Parry. He passed Behring's Straits and penetrated as far as lat. 71° 23′ 31″ N., and long. 156° 21′ 30″ W., reaching a point only 146 miles west of that reached by Franklin's expedition from the Mackenzie River. The whole voyage lasted more than three years; and in the course of it Beechey discovered several islands in the Pacific, and an excellent harbour near Cape Prince of Wales. A full narrative of his voyage was published in 1825–28. From 1835 to 1847 Captain Beechey was employed on the coast survey of South America and Ireland. He was then appointed by Government to preside over the Marine Department of the Board of Trade. In 1854 he was made rear-admiral, and in the following year was elected president of the Geographical Society. He died on the 29th Nov. 1856.

BEECHEY, SIR WILLIAM, R.A., a fashionable portrait-painter, born at Burford in December 1753, was originally bred as a conveyancer, but a strong love for painting induced him to become a pupil at the Royal Academy in 1772. Some of his smaller portraits gained him considerable reputation; he began to be employed by the nobility, and in 1793 became associate of the Academy. In the same year he was made portrait-painter to Queen Charlotte, an appointment which increased his celebrity. He painted the portraits of the members of the royal family, and of nearly all the most famous or fashionable persons of the time. What is considered his finest production is a review of cavalry, a large composition, in the foreground of which he introduced portraits of George III., the Prince of Wales, and the duke of York, surrounded by a brilliant staff on horseback. It was painted in 1798, and obtained for the artist the honour of knighthood, and the rank of R.A. The earlier portraits of Beechey were carefully drawn and well finished; but in his later days the extent of his employment rendered him less careful in his design. His works are generally vigorous, but are wanting in grace and dignity. He was a good, but not an eminent portrait painter. He died in January 1839, at the advanced age of eighty-six.

BEELZEBUB. The name of the supreme god among all the Syro-Phœnician peoples was Baal, *i.e.*, *lord* or *owner*; and by adding to it *zebub*, insect, the proper name Baalzebub was formed, the god of Ekron according to 2 Kings i. 2, the fly-god, the averter of insects, similar to the Ζεύς *ἀπόμυιος*, *μυίαγρος*, and the Hercules *μυίαγρος*; so that Clemens Alexandrinus speaks of a Hercules *ἀπόμυιος* worshipped in Rome. Hug's hypothesis that this Philistine god was the dung-beetle, the *Scarabæus pillularius*, worshipped in Egypt, cannot be accepted. Beelzebub was so named not from his form, but from his supposed power of driving away noxious flies. In the New Testament the word is applied to Satan, the ruler or prince of the demons (Matt. x. 25, xii. 24, 27; Mark iii. 22; Luke xi. 15, 18, 19). But the best Greek MSS. read *Βεελζεβούλ*, Beelzebul, in the Gospels,—an orthography followed by the latest critical editions, though the Syriac and Vulgate versions have Beelzebub, which is also recommended by Jerome. What is the origin of Beelzebub? The most obvious derivation of it is בְּעַל־זְבוּל, *Baal* (or *lord*) *of the dwelling*, a name of Saturn among the Phœnicians, according to Movers, synonymous with בְּעַל־מָעוֹן. So it may mean *Baal of the heavenly dwelling* or *habitation*, just as Satan is termed in the epistle to the Ephesians (ii. 2) prince of the power of the air." Others suppose that Beelzebul arose from Beelzebub by a pun on the part of the later Jews, who wished to throw ridicule on idols by forming the appellation *lord of dung*,—זְבַל or זבל meaning *dung* in the Targumic and Talmudic dialects. This is improbable, because Beelzebul was not a current name in Jewish literature. Somewhat different is the opinion of Lightfoot, based upon various Talmudic passages, in which *zebul*,

dung, or *a dunghill*, is applied to an idol or idolatry and the verb זָבַל, *to dung*, to sacrificing to an idol,[1] so that בְּעַל־זְבוּל is not a proper name, but a general and common one, equivalent to *the lord of idolatry*, *prince of the demons*, the most devilized of all devils = *ἄρχων τῶν δαιμονίων*. In this way the word זְבוּל has the secondary sense of *idol*, and Baalzebul has no connection with the proper name Beelzebub. The passages in question are far from supporting the hypothesis. *Zebul* is not a Hebrew word. It has not the sense of *idol* in Chaldee. In the Targums *zebel* has no other signification than *dung*. A nickname or opprobrious epithet is not a real name or the signification of a word properly so called. All that the quotations fairly imply is, that an ignominious name was sometimes given to idols or idolatry, *dung*, or a *thing of dung*. Hence Lightfoot and those who follow him, such as Gesenius and Schleusner, are in error. If *zebul* be a part of the name Beelzebul added to it designedly, it is more probable that it was meant to express contempt for a leading god of the heathen. But it is exceedingly doubtful whether it was common as early as the New Testament. According to the Gospels, the Jews attributed the power of expelling demons which Jesus possessed to his connection with Satan, the ruler of the demons; and their notions of Satanic influence forbid the idea of applying the name *dung-god* (if such was its meaning) to a being like the devil. We reject the two leading derivations of the word Beelzebul, whether that sanctioned by Lightfoot and Buxtorf, *lord of dung*, which is adopted by Fritzsche and De Wette; or *lord of the dwelling*, followed by Paulus, Jahn, and Hitzig. Meyer ingeniously supposes that the latter is favoured by the words of Matthew x. 25, where *οἰκοδεσπότης* is thought to be assigned to Jesus significantly, in allusion to Βεελζεβούλ; and as *δεσπότης* corresponds to בַּעַל, an analogous word must be found for *οἶκος*, viz., זְבוּל. The reasoning, however, is fallacious. The reading in Matthew x. 25 is not certain,—Lachmann following the Vatican MS. in giving *τῷ οἰκοδεσπότῃ* instead of the usual *τὸν οἰκοδεσπότην*. Then, again, the passage is unique in saying that the Jews gave Jesus the surname Beelzebul. We learn from Matth. xii. 24 that they said he cast out demons "by *Beelzebul*, prince of the demons," which does not agree with x. 25, but is a more intelligible and likely statement. That they actually called Jesus Beelzebul is a doubtful assertion, notwithstanding Meyer's affirmation to the contrary. The change of the final letter from *b* to *l* seems to have been accidental. Such alterations are not unusual, as Bab-el-mandel from Bab-el-mandeb, Rabbuli from Rabbuni, Ambakum from Habakkuk. *L*, being a softer sound than *b*, was a natural change. Why the name Beelzebul was applied to Satan at the time of Christ is obscure. Probably it originated in no specific reason. The appellation of a leading god was readily transferred to the devil. It is therefore idle to inquire on what grounds the Jews assigned to the Beelzebub of Ekron the peculiar position of "prince of the demons." The Philistine god had become but a name.

BEER. See Brewing.

BEERSHEBA, now Bir-es-Seba, a place in the southernmost part of Canaan, 27 miles S.E. from Gaza, celebrated for the sojourn of the patriarchs. The name, signifying the *well of the oath*, was bestowed in allusion to the covenant made there between Abraham and Abimelech, and is frequently referred to in the Scriptures in describing the extent of the country—"*from Dan to Beersheba*." The place is mentioned by Eusebius and Jerome in the 4th century as a large village, and the seat of a Roman garrison. At a later period it seems to have been one of the episcopal cities of Palestine, and some of its churches were standing in the 14th century. Hardly any remains of its buildings are now left, but its two wells are still open, and afford an abundant supply of pure water, which stands in the larger at a depth of 44½ feet, and in the smaller at a depth of 12. (See Robinson's *Researches*, i. 301.)

BEET. A considerable number of varieties of the genus *Beta* (Nat. Ord. *Chenopodiaceæ*) are cultivated for use on account of their large fleshy roots. The beets which are grown as root-plants, under the names of mangel-wurzel or mangold, field-beet, and garden-beet, are generally supposed to be cultivated varieties of the sea-beet (*B. maritima*). The cultivation of beet as a field crop is treated under Agriculture (vol. i. p. 381); and in relation to the production of sugar, for which purpose certain varieties of beet stand next in importance to the sugar cane, see Sugar. The garden-beet has been cultivated from very remote times as a salad plant, and for general use as a table vegetable. The variety most generally grown has long, tapering, carrot-shaped roots, the "flesh" of which is of a uniform deep red colour throughout, and the leaves brownish red. It is boiled and cut into slices for being eaten cold; and it is also prepared as a pickle, as well as in various other forms. Beet is in much more common use on the Continent as a culinary vegetable than in Great Britain, where it has, however, been cultivated for upwards of two centuries. The leaves of the white Sicilian beet and the Swiss chard beet, both varieties of *Beta cicla*, are used for salads and otherwise as culinary vegetables.

BEETHOVEN, Ludwig van, is in music what Shakespeare is in poetry, a name before the greatness of which all other names, however great, seem to dwindle. He stands at the end of an epoch in musical history, marking its climax; but his works at the same time have ushered in a new phase of progress, from which everything that is great in modern music has taken its rise. This historic side of his genius will have to be further dealt with when the progress of musical art is traced in its continuity. (See article Music, historic section.) At present we have to consider Beethoven chiefly as a man and an individual artist, showing at the same time the reciprocal relations between his life and his work. For although the most ideal artist in that most ideal of arts—music—he is always inspired by the deepest sense of truth and reality. The grand note of sadness resounding in his compositions is the reverberation of personal suffering. He was a great artist only because he was a great man, and a sad man withal.

The family of Beethoven is traceable to a village near Lowen in Belgium, in the 17th century. In 1650 a member of this family, a lineal ancestor of our composer, settled in Antwerp. Beethoven's grandfather, Louis, owing to a quarrel with his family, left Belgium for Germany, and came to Bonn in 1732, where his musical talents and his beautiful voice did not long remain unnoticed. The archbishop of Cologne, an art-loving prelate, received him among his court-musicians; and the same position afterwards was held by Ludwig's son, Johann, our composer's father. The latter was married to Maria Magdalena Keverich, daughter of a cook, and widow of a *valet-de-chambre* of the elector of Trèves. The day of our composer's birth is uncertain; he was baptised Dec. 17, 1770, and received

[1] See *Hierosol. Berachoth*, fol. 12, 13; and *Midrash Shir*, fol. 2, 1.

the name of his paternal grandfather Louis, or, in its Germanized form, Ludwig. Beethoven himself seems to have considered the 16th December of the said year his birthday, but documentary evidence is wanting. At one period of his life he believed himself to have been born in 1772, being most likely deceived on the point by his father, who tried to endow his son and pupil with the *prestige* of miraculous precocity. No less uncertain than the date is the exact place of the great composer's birth; two houses in Bonn claim the honour of having been the scene of the important event. The youth of Beethoven was passed under by no means happy circumstances. His father was of a rough and violent temper, not improved by his passion for intoxicating drink, nor by the dire poverty under which the family laboured. His chief desire was to reap the earliest possible advantage from the musical abilities of his son, who, in consequence, had at the age of five to submit to a severe training on the violin under the father's supervision. Little benefit was derived from this unsystematic mode of instruction, which, fortunately, was soon abandoned for a more methodical course of pianoforte lessons under a musician of the name of Pfeiffer. Under him and two other masters, Van der Eden and Neefe, Beethoven made rapid progress as a player of the organ and pianoforte; his proficiency in the theoretical knowledge of his art the aspiring composer soon displayed in a set of Variations on a March published in 1783, with the inscription on the title-page, "*par un jeune amateur, Louis van Beethoven, âgé dix ans*," a statement the inaccuracy of which the reader will be able to trace to its proper source. In 1785 Beethoven was appointed assistant of the court-organist Neefe; and in a *catalogue raisonné* of the musicians attached to the court of the archbishop, he is described as "of good capacity, young, of good, quiet behaviour, and poor." The elector of Cologne at the time was Max Franz, a brother of the Emperor Joseph, who seems to have recognized the first sparks of genius in the quiet and little communicative youth. By him Beethoven was, in 1787, sent for a short time to Vienna, to receive a few lessons from Mozart, who is said to have predicted a great future for his youthful pupil. Beethoven soon returned to Bonn, where he remained for the next five years in the position already described. Little remains to be said of this period of apprenticeship. Beethoven conscientiously studied his art, and reluctantly saw himself compelled to alleviate the difficulties of his family by giving lessons. This aversion to making his art useful to himself by imparting it to others remained a characteristic feature of our master during all his life. Of the compositions belonging to this time nothing now remains; and it must be confessed that, compared with those of other masters, of Mozart or Handel, for instance, Beethoven's early years were little fertile with regard either to the quantity or the quality of the works produced. Amongst the names connected with his stay at Bonn we mention only that of his first friend and protector, Count Waldstein, to whom it is said Beethoven owed his appointment at the electoral court, and his first journey to Vienna. To the latter city the young musician repaired a second time in 1792, in order to complete his studies under Haydn, the greatest master then living, who had become acquainted with Beethoven's talent as a pianist and composer on a previous occasion. The relation of these two great men was not to be fruitful or pleasant to either of them. The mild, easy-going nature of the senescent Viennese master was little adapted to inspire with awe, or even with sympathy, the fiery Rhenish youth. Beethoven in after life asserted that he had never learned anything from Haydn, and seems even to have doubted the latter's intention of teaching him in a proper manner. He seems to have had more confidence in the instruction of Albrechtsberger, a dry but thorough scholar. He, however, and all the other masters of Beethoven agree in the statement, that being taught was not much to the liking of their self-willed pupil. He preferred acquiring by his own toilsome experience what it would have been easier to accept on the authority of others. This autodidactic vein, inherent, it seems, in all artistic genius, was of immense importance in the development of Beethoven's ideas and mode of expression.

In the meantime his worldly prospects seemed to be of the brightest kind. The introductions from the archbishop and Count Waldstein gave him admittance to the drawing-rooms of the Austrian aristocracy, an aristocracy unrivalled by that of any other country in its appreciation of artistic and especially musical talent. Vienna, moreover, had been recently the scene of Mozart's triumphs; and that prophet's cloak now seemed to rest on the shoulders of the young Rhenish musician. It was chiefly his original style as a pianist, combined with an astonishing gift of improvisation, that at first impressed the amateurs of the capital; and it seems, indeed, that even Haydn expected greater things from the executive than from the creative talent of his pupil. It may be added here, that, according to the unanimous verdict of competent witnesses, Beethoven's greatness as a pianoforte player consisted more in the bold, impulsive rendering of his poetical intentions than in the absolute finish of his *technique*, which, particularly in his later years, when his growing deafness debarred him from self-criticism, was somewhat deficient.

As a composer Beethoven appeared before the public of the Austrian capital in 1795. In that year his Three Trios for Pianoforte and Strings were published. Beethoven called this work his *Opus* 1, and thus seems to disown his former compositions as juvenile attempts unworthy of remembrance. He was at that time twenty-five, an age at which Mozart had reaped some of the ripest fruits of his genius. But Beethoven's works are not like those of the earlier master, the result of juvenile and all but unconscious spontaneity; they are the bitter fruits of thought and sorrow, the results of a passionate but conscious strife for ideal aims. Before considering these works in their chief features, we will add a few more remarks as to the life and character of their author. The events of his outward career are so few and of so simple a kind that a continuous narrative seems hardly required. The numerous admirers whom Beethoven's art had found amongst the highest circles of Vienna,—Archduke Rudolf, his devoted pupil and friend, amongst the number,—determined him to take up his permanent residence in that city, which henceforth he left only for occasional excursions to Baden, Mödling, and other places in the beautiful surroundings of the Austrian capital. It was here, in his lonely walks, that the master received new impulse from his admiring intercourse with nature, and that most of his grandest works were conceived and partly sketched. Except for a single artistic tour to Northern Germany in 1796, Beethoven never left Vienna for any length of time. A long-projected journey to England, in answer to an invitation of the London Philharmonic Society, was ultimately made impossible by ill-health. Beethoven's reputation as a composer soon became established beyond the limits of his own country, notwithstanding the charges of abstruseness, unpopularity, and the like, which he, like most men of original power, had to submit to from the obtuse arrogance of contemporary criticism. The summit of his fame, so far as it manifested itself in personal honours conferred upon him, was reached in 1815, when Beethoven celebrated by a Symphony the victories of the Allies over the French oppressor, and was rewarded by the applause of the sovereigns of Europe, assembled at the Congress of Vienna.

In the same year he received the freedom of that city, an honour much valued by him. After that time his immediate popularity began to some extent to decline before the ephemeral splendour of the composers of the day; and the great master seemed henceforth to speak more to coming generations than to his ungrateful contemporaries. When, however, on rare occasions he emerged from his solitude, the old spell of his overpowering genius proved to be unbroken. In particular, mention must be made of that memorable *Academie* (concert) in 1824, at which his 9th Symphony, and parts of the grand *Missa Solemnis*, were performed, producing a storm of applause—inaudible, alas! to the composer, who had to be turned round by one of the singers to realize, from the waving of hats and handkerchiefs, the effect of his work on the excited multitude

The last-mentioned incident leads us to one of the most tragic features of Beethoven's life. By the bitter irony of fate, he who had given to thousands enjoyment and elevation of the heart by the art of sound, was himself deprived of the sense of hearing. The first traces of beginning deafness showed themselves as early as 1797, and were perceived by the master with an anxiety bordering on despair. Physicians and quacks were consulted with eagerness, but all their efforts (partly impaired, it must be confessed, by the unruly disposition of the patient) proved unable to stem the encroaching evil. The Royal Library of Berlin possesses a melancholy collection of ear-trumpets and similar instruments, partly made expressly for Beethoven to assist his weakened sense, but all to no avail. In his latter years conversation with him could be carried on by writing only, and of the charms of his own art he was wholly deprived. But here, again, the victory of mind over matter,—of genius over circumstance,—was evinced in the most triumphant manner. It has been asserted, not without reason, that the euphonious beauty of some of Beethoven's vocal compositions has suffered through his inability to listen to them; but how grand is, on the other hand, the spectacle of an artist deprived of all intercourse with what to him in this world was dearest, and yet pouring forth the lonely aspirations of his soul in works all the more sublime as we seem to hear in them the voice of the innermost spirit of mankind, inaudible to the keen ears of other mortals. If in this manner the isolation of Beethoven further sublimated his efforts as an artist, it, on the other hand, poignantly intensified his sufferings as a man. His was a heart open to the impressions of friendship and love, and, in spite of occasional roughness of utterance, yearning for the responsive affection of his kind. It is deeply touching to read the following words in the master's last will, written during a severe illness in 1802:—"Ye men," Beethoven writes, "who believe or say that I am inimical, rough, or misanthropical, how unjust are you to me in your ignorance of the secret cause of what appears to you in that light. . . . Born with a fiery, lively temper, and susceptible to the enjoyment of society, I have been compelled early to isolate myself and lead a lonely life; whenever I tried to overcome this isolation, oh! how doubly bitter was then the sad experience of my bad hearing, which repelled me again; and yet it was impossible for me to tell people, 'Speak louder, shout, for I am deaf.'"

Domestic troubles and discomforts contributed in a minor degree to darken the shadow cast over our master's life by the misfortune just alluded to. Although by no means insensible to female beauty, and indeed frequently enraptured in his grand, chaste way with the charms of some lady, Beethoven never married, and was, in consequence, deprived of that feeling of home and comfort which only the unceasing care of refined womanhood can bestow. His helplessness and ignorance of worldly matters completely exposed him to the ill-treatment of servants, frequently, perhaps, excited by his own morbid suspicions and complaints. On one occasion the great master was discovered with his face bleeding from the scratches inflicted by his own valet. It was from amidst such surroundings that Beethoven ascended to the sublime elevation of such works as his *Missa Solemnis* or his 9th Symphony. But his deepest wounds were to be inflicted by dearer and nearer hands than those of brutal domestics. Beethoven had a nephew, rescued by him from vice and misery, and loved with a more than father's affection. His education the master watched with unceasing care. For him he hoarded with anxious parsimony the scanty earnings of his artistic labour. Unfortunately, the young man was unworthy of such love, and at last disgraced his great name by an attempt at suicide, to the deepest grief of his noble guardian and benefactor.

Beethoven died on March 27, 1827, during a terrible thunderstorm. It ought to fill every Englishman's heart with pride that it was given to the London Philharmonic Society to relieve the anxieties of Beethoven's deathbed by a liberal gift, and that almost the last utterances of the dying man were words of thanks to his friends and admirers in this country.

Beethoven's compositions, 138 in number, comprise all the forms of vocal and instrumental music, from the sonata to the symphony,—from the simple song to the opera and oratorio. In each of these forms he displayed the depth of his feeling, the power of his genius; in some of them he reached a greatness never approached by his predecessors or followers. His pianoforte sonatas have brought the technical resources of that instrument to a perfection previously unknown, but they at the same time embody an infinite variety and depth of emotion. His nine symphonies show a continuous climax of development, ascending from the simpler forms of Haydn and Mozart to the colossal dimensions of the *Choral Symphony*, which almost seems to surpass the possibilities of artistic expansion, and the subject of which is humanity itself with its sufferings and ideals. His dramatic works—the opera *Fidelio*, and the overtures to *Egmont* and *Coriolanus*—display depth of pathos and force of dramatic characterization. Even his smallest songs and pianoforte-pieces reflect a heart full of love, and a mind bent on thoughts of eternal things.

Beethoven's career as a composer is generally divided into three periods of gradual progress. We subjoin a list of his most important compositions, grouped according to the principle indicated.

The first period extends to the year 1800. At the beginning we see Beethoven under the influence of his great predecessors, Haydn and Mozart, but progressing in rapid strides towards independence of thought and artistic power. To this time belong Three Trios for Pianoforte and Strings, *Op.* 1; Sonata for Pianoforte in E flat, *Op.* 7; Trio for Pianoforte and Strings in B flat, *Op.* 11; *Sonate Pathétique;* First Concerto for Pianoforte and Orchestra in C, *Op.* 15; *Adelaida* (composed 1797); also the celebrated Septuor, *Op.* 20, and the First Symphony, *Op.* 21 (the last two works published in 1800).

The second period, from 1800–1814, marks the climax of formal perfection. The works of this time show the highest efforts of which music as an independent art is capable. We mention the Mass in C, *Op.* 86; our master's only opera, *Fidelio*, and his overture and incidental music to Goethe's *Egmont;* the Symphonies, Nos. 2–8, amongst which those called the *Pastoral*, the *Eroica*,[1] and those

[1] This symphony was originally written in celebration of Napoleon, at that time consul of the French Republic. When Beethoven heard of his assuming the imperial title, he tore off the dedication and trampled it under foot.

in C minor and A major deserve special mention; Concerto for the Violin, *Op.* 61; Concerti for the Pianoforte, Nos. 3–5; Overtures to ***Prometheus***, ***Coriolanus***, ***Fidelio***, and ***King Stephen***; also numerous sonatas for the pianoforte, quartets, quintets, and other pieces of chamber music.

The third period may be described as that of *poetic* music,—a distinct poetic idea becoming the moving principle before which the forms of absolute music have to yield. Beethoven has, by the works belonging to this class, ushered in a new phase of music, as will be further shown in the historical sketch of the art. We name that unequalled master-piece of symphonic art, the Ninth or *Choral Symphony*; the *Missa Solemnis*; the Sonatas for Pianoforte, numbered respectively *Op.* 101, 102, 106, 109, 110, 111; the marvellous Quartets for Strings, *Op.* 127, 130, 132, 135; also the 33 Variations on a Valse by Diabelli, *Op.* 120.

For fuller information on the great master's life and works than our limited space has permitted us to give, we refer the reader to the biographical and critical works of Schindler, Thayer, Nohl, Marx, and Nottebohm. (F. H.)

BEETLE, a name commonly applied to those insects which form the order *Coleoptera* ("sheathwinged"), and which are readily distinguished from all others by the nature of the two upper wings. These are formed of a hard, horny substance known as *chitin*; and, although useless in flight, they serve as shields for the protection of the delicate wings underneath, while in many cases their hardness protects the beetle itself from the attacks of insectivorous birds. In some instances the *elytra*, as those upper wings are called, are firmly soldered together, and such species are thus rendered incapable of flight. Owing to the beauty of many of the exotic species, and the ease with which they can be preserved, beetles have been collected with great diligence by entomologists, so that nearly 80,000 species, it is estimated, have already been described. Among the members of so large a group it need hardly be said that the greatest diversity exists in form and habits. They are all, however, provided with a masticatory mouth; and in such predatory species as the Tiger Beetles, the mandibles are largely developed, and often armed with acute teeth. Many of them are carnivorous, feeding on other insects, and on decaying animal matter; but the larger proportion live on the fruits, leaves, and stems of plants, in many instances doing great damage to cereal crops and forest trees. In Germany, in the year 1783, a million and a half of trees are said to have been destroyed in the Harz Forest alone by means of two small species of wood-boring beetles; and in North America at the present time the potato crop is being annually blighted by the devastations of the larvæ of what is known as the Potato Beetle (*Doryphora decemlineata*). Beetles undergo complete metamorphosis, passing from the larva to the pupa stage, in which they sometimes remain for several years before emerging as full-formed insects; others, however, undergo all the changes from egg to beetle in a few months. Many of those insects, such as the Goliath and Hercules Beetles, attain gigantic proportions, measuring often 6 inches long, exclusive of antennæ, and 2 inches broad; and many bear on the upper surface of their bodies curious horn-like projections. Others, as the Diamond Beetle of Brazil, are adorned with the most brilliant colours, showing a beautiful metallic lustre; and the elytra of such species are now largely used by jewellers in the manufacture of personal ornaments. See COLEOPTERA and INSECTS.

BEGAS, KARL, a distinguished German historical painter, was born at Heinsberg in 1794, and died in 1854. His father, a retired judge, destined him for the legal profession, but the boy's tastes pointed definitely in another direction. Even at school he was remarked for his wonderful skill in drawing and painting, and in 1810 he was permitted to visit Paris in order to perfect himself in his art. He studied for eighteen months in the atelier of Gros, and then began to work independently. In 1814 his copy of the Madonna della Sedia was bought by the king of Prussia, who was attracted by the young artist, and did much to advance him. He was engaged to paint several large Biblical pictures, and in 1825, after his return from Italy, continued to produce paintings which were placed in the churches of Berlin and Potsdam. Some of these were historical pieces, but the majority were representations of Scriptural incidents. Begas was also celebrated as a portrait painter, and supplied to the royal gallery a long series of portraits of eminent Prussian men of letters. At his death he held the post of court painter.

BEGBAZAAR, or BEIBAZAAR, a town of Asiatic Turkey, in the Anatolian province of Angora, situated on the Sangarius or Sakaria, about 52 miles W. of the provincial capital. Its houses are two stories in height, and roofed with shingles. Carpet-weaving is carried on in the town, and rice, cotton, and fruits are cultivated in the neighbourhood. The pears that are sold in Constantinople as the produce of Angora are really grown by the people of Begbazaar. Numerous remains of ancient works in marble are found throughout the town. Population, 4750.

BEGHARDS AND BEGUINES. The nature and history of the Beghards is one of the obscurest problems in mediæval times, and nothing very certain has been ascertained. During the Middle Ages there were formed, alongside of the regular orders, companies of men and women who devoted themselves to a religious life, but did not bind themselves by strict vows. The design was to enable men and women, who did not mean to separate themselves entirely from the world, to lead, nevertheless, what, in the Middle Ages, was esteemed *the* religious life. Such companies were the Tertiarii of the Dominican and Franciscan orders, and at first the Beghards and Beguines were similarly constituted. The first notices we have of them tell us that, in the end of the 12th century, in several of the towns of the Netherlands, companies of women formed themselves together, under a simple rule, for the purpose of taking care of the sick and for other charitable objects. They were generally widows and maidens of high rank, and were called Beghinæ, or Beguinæ, or Beguttæ. The origin of the word is very obscure. Some time later, companies of men were formed in a similar way, and under the same rule. They took no vows, and were at liberty to leave the company when they liked. The men were called Beghards. In the 14th century these Beghards seem to have attached themselves to the Franciscans, and to have been instrumental in exciting to revolt that portion of the order which rebelled against the Pope. For some period, indeed, the terms Fratricelli or Spirituales (the two names for the rebel Franciscans) are used synonymously with Beghards. It is believed that the Arabian pantheism of Averroes had become diffused among many of the mystical sects, and that societies, originally purely religious, had become partly political. We know, at all events, that, in the 14th century, the Beghards were in close alliance with the communistic and pantheistic "Brethren of the Free Spirit." Clement V. denounced them at the Council of Vienna, and launched two bulls against them; the Inquisition was ordered to suppress them; and Pope John XXII., while he protected the Beguines, persecuted the Beghards. Such Beghards as still remained were absorbed in the Tertiarii of the Franciscans in the 17th century; but small communities of Beguines—Beguinages, as they are called—still exist in the Netherlands, and in their organization are somewhat similar to many Anglican sisterhoods. (*Cf.* Mosheim, ***De Beghardis et Beguinabus***, ***the*** book upon the subject,

and Hahn's *Geschichte der Ketzer im Mittelalter*. For the meaning of the word see Du Cange, *Gloss.*)

BEHAR, a province of British India, under the jurisdiction of the Lieutenant-Governor of Bengal, situated between 24° and 28° N. lat., and 83° and 89° E. long. It comprises the districts of Champáran, Tirhut, Sháhábád, Sárán, Patná, Purniah, Bhágalpur, and the Santál parganás; and is bounded on the N. by the independent kingdom of Nepál; on the E. by the Rájsháhí and Bardwán divisions of Bengal proper; on the S. by the Chhotá Nágpur division; and on the W. by the North-Western Provinces. The general aspect of the country is flat, except in the district of Monghir, where detached hills occur, and in the south-east of the province, where the Rájmahal and Santál ranges abut upon the plains.

Behar abounds in great rivers, such as the Ganges, with its tributaries, the Ghagrá, Gandak, Kusí, Mahánandá, and Son. The Ganges enters the province near the town of Baxar, flows eastward, and passing the towns of Dinájpur, Patná, Monghir, and Colgong, leaves the province at Rájmahal. It divides the province into two almost equal portions; north of the river lie the districts of Sáran, Champáran, Tirhut, Purniah, and part of Monghir and Bhágalpur, and south of it are Sháhábád, Patná, Gayá, the Santál parganás, and the rest of Monghir and Bhágalpur. The Ganges and its northern tributaries are navigable by country boats of large burden all the year round. The Son (the most important of the southern tributaries) enters the province in the extreme south-west, and forming for a short distance its boundary in that direction, flows north, past Rhotásgarh and Arah, separating the districts of Sháhábád from those of Gayá and Patná, and joins the Ganges opposite Chuprá. It has a very wide bed, and pours down its waters with great velocity during the rains. The principal hills within the province are the Moher hill in the district of Gayá, 1620 feet; Santál parganá hills, 800 to 1600 feet; Rájmahal and Monghir hills, 1500 feet; and Rájgarh hill in Patná, 1200 feet above sea-level.

Behar Province contains eight districts, with an area of 42,417 square miles, and a total population in 1872 of 19,736,101 souls, inhabiting 48,285 villages or townships, and 3,252,036 houses; persons per square mile, 465; per village, 409. The males numbered 9,797,649, or 49·6 per cent., and the females, 9,938,452, or 50·4 per cent., of the total population. Of the provincial population, 16,526,850, or 83·7 per cent., were Hindus; 2,636,053, or 13·4 per cent., Mahometans; 54 Buddhists; 8063 Christians; and 565,081, or 2·9 per cent., of unspecified religion, mostly aborigines. Of the male adults, 3,613,231 are returned as agriculturists, and 2,489,557 non agriculturists. The aboriginal tribes consist of the Bhars, Cherus, Dhángars, Kanjhárs, Kharwárs, Kols, Mals, Naiyás, Nats, Paharias, Santáls, and Tharus. The census of 1872 returned 49 towns as containing upwards of 5000 inhabitants, particulars of which will be found in the accounts of the districts within which they are situated. Rice, wheat, barley, pulses, maize, and various kinds of millets, form the principal food-grains of the province. Rice is the main staple of food; but in elevated and dry localities, wheat, maize, millet, and peas are substituted. Potatoes, cabbages, &c., were introduced by Europeans, and are now largely cultivated. Many kinds of fruits and vegetables are also produced. The commercial staples consist of oil-seeds, opium, indigo, sugar, cotton, and saltpetre. Upwards of 800,000 tons of oil-seeds were exported from Behar in 1872. The principal marts for oil-seeds are Revelganj, in the Sáran district, and Roshrá in Tirhut. The cultivation of opium is a Government monopoly, and no person is allowed to grow the poppy except on account of Government. The Behar Opium Agency has its headquarters at the town of Patná. Annual engagements are entered into by the cultivators, under a system of pecuniary advances, to sow a certain quantity of land with poppy, and the whole produce in the form of opium is delivered to Government at a fixed rate. The area under poppy cultivation in the Behar Agency in 1872 amounted to 330,925 acres. The Behar indigo, generally called Tirhut indigo, yields about one-half of the total produce of that dye which is annually exported from Calcutta. In the Bhágalpur division there are 44 factories, yielding on an average about 500 tons of indigo a year. In the Patná division, indigo cultivation is almost entirely confined to the north of the Ganges, in the districts of Tirhut, Sáran, and Champáran, which in 1872 contained 104 factories, including outworks, and yielded 1958 tons of the dye. The indigo industry is almost entirely conducted by Europeans, and the total capital invested in the business in Behar is estimated at upwards of a million sterling. Large quantities of sugar are exported, but the cotton grown in the province is not sufficient for the requirements of the people, and has to be supplemented by imports of raw cotton and English piece goods. Saltpetre is largely refined in Tirhut, Sáran, and Champáran, and is exported both by rail and river to Calcutta; the quantity exported by river in 1872 being 22,749 tons. The manufactures of less importance are tasar-silk, paper, blankets, brass utensils, fire-arms, carpets, coarse cutlery and hardware, leather, ornaments of gold and silver, &c. Of minerals—lead, silver, and copper exist in the Bhágalpur division, but the mines are not worked. One coal-mine is worked in the Santál parganás. Before the construction of railways in India, the Ganges and the Grand Trunk road afforded the sole means of communication from Calcutta to the North-Western Provinces. But now the railroad is the great highway which connects Upper India with Lower Bengal. The East Indian Railway runs throughout the length of the province; total length of rail, upwards of 500 miles. Besides the Grand Trunk road, the other important roads in the province are—(1), Road from Synthia Railway Station to Bhágalpur; (2), Darjiling road, from Kárágolá to Silíguri; (3), from Shahrghátí on the Grand Trunk road to Patná city, and thence to Tirhut town. There are also many local roads under the management of the district road committees. The gross revenue of the province in 1872 amounted to £1,596,952, of which £1,184,906, or 74 per cent., was from land. In 1872 the 8 districts of the province were divided into 37 executive subdivisions, and contained 52 civil judges and 80 magistrates. The total police force (regular, municipal, and village) consists of 60,028 men; cost, £210,943. In 1872 there were 215 Government and aided schools, attended by 9454 pupils, and maintained at a total cost of £17,835, of which Government contributed £10,328. These are exclusive of unaided schools. The census of 1872 returned the total number of schools, aided and unaided, in the province at 4781. Bengali is the language in the eastern part of the province; but Hindi, one of the dialects of Sanskrit, is the language of the rest. The Mahometan population use Hindustáni or Urdu, a language of modern origin, formed from the fusion of Persian and Arabic with Hindi. The climate of Behar is very hot from the middle of March to the end of June, when the rains set in, which continue till the end of September. The cold season, from October to the first half of March, is the pleasantest time of the year. The total rainfall in 1872 varied from 32 to 60 inches in different localities; minimum temperature in December, 53°; maximum in May, 105°.

In ancient times Behar comprised the dominions of the kings of Magadha, who at one time were the lords paramount of India, and whose court is represented as one of the most brilliant that ever existed. Alexander the Great when he invaded India intended to push his conquests to Palibothra, the capital of Magadha, whose monarch he heard could oppose him with 30,000 cavalry, 600,000 infantry, and 9000 elephants. Their highest point of grandeur was supposed to have been attained at the time of Seleucus Nicator, one of the immediate successors of Alexander, who invaded Magadha. According to the Greek historians he was victorious, but this is doubtful, as he relinquished all the Macedonian conquests to the east of the Indus, and gave his daughter in marriage to Chandra Gupta, the reigning king. At this time Magasthenes was appointed to represent him at Magadha court. The Magadha monarchs encouraged arts and learning, constructed roads, and sent their fleets across the Bay of Bengal to colonize Java, Bali, and other islands in the Indian Archipelago. The Magadha kingdom flourished from the 4th century before the Christian era to the 5th century after it. But ancient Behar is far more celebrated in another respect. Six centuries before the Christian era it was the cradle of Buddhism when that religion was in its infant state. It sent its missionaries to Ceylon, China, Thibet, and Tartary, and the religion they taught is still followed by 300 millions of people. Behar is a sacred spot in the eyes of the Chinese and other Buddhist nations. In 1202 A.D. Behar fell into the hands of the Mahometans without a struggle, and from this time it formed one of the three subahs or provinces under the rulers of Bengal. In the time of Akbar it comprised the seven *sarkárs* of Monghir, Champáran, Hájípur, Sáran, Tirhut, Rohtás, and Behar. It came into the possession of the East India Company with the acquisition of the Díwání in 1765, when the province was united with Bengal. In 1857 two zamíndárs, Umar Sinh and Kumár Sinh, rebelled against the British Government, and for some months held the ruinous fort of Rohtás against the English.

BEHAR, a magisterial subdivision, and a town of Patná district. The SUBDIVISION was formed in 1846. It has

an area of 792 square miles, with a total population of 570,888 souls, the average population per square mile being 721. BEHAR TOWN is situated in 25° 10′ N. lat., and 85° 35′ E. long. It was formerly the capital of a subah or governorship under the Mahometans, but at present it is merely a subdivisional town. Population in 1872:—Hindus, 31,006; Mahometans, 13,282; others, 7; total, 44,295. Municipal income, £1100; expenditure, £1120; rate of taxation, 6d. per head of population.

BEHBEHAN, a town of Persia, in the province of Fars, pleasantly situated in the middle of a highly-cultivated plain, which is watered by the Rivers Zab and Jerahi. The walls are about three miles in circumference; and there is a castle called Kaláh Náranj, or Orange Castle, in the S.E. corner. The population is variously estimated at 10,000 and at 4000, the latter more probably correct, as the place has suffered from plague and oppression.

BEHEM, or BEHAIM, MARTIN, a well-known navigator and cartographer, was born at Nuremberg about 1436. Having entered the service of Portugal, he was appointed, in 1484, to act as geographer in the expedition of Diego Cam to the western coast of Africa, and on his return to Lisbon received the honour of knighthood in reward for his services. He was afterwards employed by the king in various capacities, and visited the capital from time to time in connection with his engagements; but, after his marriage in 1486, his principal residence seems to have been at Fayal, in the Azores, where his father-in-law, Job Huerter, held the rank of governor of the Flemish colony. On a visit to his native city in 1492, he constructed a terrestrial globe, in which he incorporated the discoveries of Marco Polo and other recent travellers. The globe is still preserved in the family, and has frequently been reproduced by engraving. (See Doppelmayr, *Hist. Nachricht v. Nürnberg. Mathem. u. Künstler*, 1730; Pigafetta, *Prem. voy. autour du Monde*, 1802; and atlas to Vivien de Saint Martin's *Hist. de la Geog.*, 1874.) Behem's scientific attainments have been very variously estimated,—some placing him in the very first rank among the geographers of his time, while others maintain that he hardly reached the level of the ordinary Portuguese chart-makers. Blunders of 16 degrees are found on his globe in the localization of places which he himself visited, while in the contemporaneous maps errors of more than one degree were comparatively rare. It is generally agreed that he had no share in Transatlantic discovery, and though Columbus and he were in Portugal at the same time, no connection between the two has been established. He died at Lisbon in 1506, or, according to his tombstone, 1507.

See Murr, *Diplomat. Gesch. des berühmten Ritters Behaim*, 1778; Humboldt, *Krit. Untersuchungen*, 1836; Ghillany, *Gesch. des Seefahrers M. Behaim*, 1853; Lelewell, *Geog. du moyen âge*, 1857; Petermann's *Mittheil.*, 1858; Peschel, *Zeitalter der Entdeckungen*, and *Gesch. der Erdkunde*, 1865; Breusing, *Zur. Gesch. der Geogr.*, 1869.

BEHISTUN, BIHSUTUN, or BISUTUN, the ancient Baghistan (*Mons Bagistanus*), a precipitous mountain or rock in Persia, remarkable for the extensive inscriptions of a very early date still preserved on some parts of its escarpment. It lies 27 miles E. of Kirmanshah, in the province of Irak Ajemi. The principal inscription is cuneiform, and relates to the victories of Darius Hystaspes, who is represented in a sculptured centre-piece as receiving the homage of a number of captives, upon one of whom he has planted his foot. The labour expended on the work must have been very great. The surface of the rock has been carefully smoothed, and pieces have had every crevice or hollow filled up with lead; the accuracy and regularity of the characters is almost unexampled, and the whole of the tablets have been carefully coated with a siliceous varnish to preserve them from the weather. Of the other inscriptions the first is in Greek and the second in Arabic, but neither is of any great importance. It was not till 1846 that the Darius tablets were translated by Sir Henry Rawlinson, who has given a complete account of his labours in the *Journ. Roy. As. Soc.* The principal notice of Behistun in the Greek or Roman writers is that of Diodorus Siculus, who tells how Semiramis visited the place on her march from Babylon to Ecbatana, and caused her own image to be sculptured on the rock. He interprets the name of the mountain by Διὸς ὄρος, the Hill of Jove, which is not very different from that proposed by modern scholars —"the dwelling of the gods." (See *Journ. R. Geog. Soc.*, 1839; *Journ. Roy. As. Soc.*, vols. x. and xii.; Ker Porter's *Travels*; Benfey's *Keilinschriften*, 1847.)

BEHMEN, JACOB. See BOEHME.

BEHN, APHRA, an English authoress of some celebrity, was born of a good family in Canterbury in the reign of Charles I., probably in 1642. Her father, whose name was Johnson, having received the appointment of lieutenant-general of Surinam, proceeded to the West Indies, taking with him his whole family. Mr Johnson died on the voyage; but his family reached Surinam, and resided there for some years. Here Aphra learned the history, and acquired a personal knowledge, of the American prince Oroonoco and his beloved Imoinda, whose adventures she has related in her novel *Oroonoco.* On her return to London she is said to have married Mr Behn, a merchant of Dutch extraction residing in that city, of whom nothing but the name has ever been known, if anything more even existed. The wit and abilities of Mrs Behn brought her into high estimation at court, and Charles II. employed her to transact some affairs of importance abroad during the Dutch war. For this purpose she went to Antwerp, where she skilfully contrived to penetrate so far into the secrets of state as to accomplish the objects of her mission; and in the latter end of 1666, by means of the influence she had gained over one Van der Albert, she wormed out of him the design formed by De Ruyter, in conjunction with the family of the De Witts, of sailing up the Thames and burning the English ships in their harbours. This she communicated to the English court, but although the event proved her intelligence to have been well founded, it was at the time disregarded,—which circumstance, together with the disinclination shown to reward her for her services, determined her to drop all further thoughts of political affairs. She returned to England, and had a narrow escape on the voyage home, the vessel in which she sailed having foundered. From this period she appears to have supported herself by her writings. Her works are numerous, and all of them are of a lively and amatory character. Her dramas are sometimes well constructed, but they are among the worst specimens of the later Stuart literature. Of her short tales, or novelettes, the only one possessing any merit is the story of *Oroonoco*, which was made the basis of Southerne's most popular tragedy. Mrs Behn died on the 16th of April 1689, and was interred in the cloisters of Westminster Abbey. Her works have passed through many editions, the latest being that published by Pearson, 1872.

BEHRING'S ISLAND, the most westerly of the Aleutian group in the North Pacific, in 55° 22′ N. lat., 166° E. long. It is rocky and desolate, and is only remarkable as being the place where the navigator Behring was wrecked and died in 1741. Population 2500.

BEHRING'S STRAIT, the narrow sea between the N.E. part of Asia and the N.W. part of North America, connecting the North Pacific with the Arctic Ocean. At the narrowest part, East Cape in Asia approaches within about 36 miles of Cape Prince of Wales on the American shore. The former is in 66° 6′ N. lat., 169° 38′ W. long.; and the latter in 65° 46′ N. lat, 168° 15′ W. long. North

and south of these points the coasts on both sides rapidly diverge. They are steep and rocky, and considerably indented. The Asiatic coast, extending from Cape Serdtzy to Cape Chukotzky, a distance of about 400 miles, presents several large and commodious bays. The strait is in general from 23 to 30 fathoms in depth, and contains a few small islands known as the Diomede Islands. Haze and fogs greatly prevail, and the temperature is low. The strait derives its name from Vitus Bering or Behring, a German in the Russian service, who discovered it in the year 1728. It was subsequently explored and described with great accuracy by Captain Cook, in 1788. (See *Arctic Papers for Expedition of* 1875.)

BEIRA, a province of Portugal, bounded on the N. by the provinces of Traz-os-Montes and Minho, E. by Spain, S. by Alemtejo and Portuguese Estremadura, and W. by the Atlantic. Area about 8586 square miles. Population in 1871, 1,294,282. It is administratively divided into the districts of Aveiro, Coimbra, Vizeu, Guarda, and Castello Branco, while it is popularly regarded as consisting of the three sections of *Beira-Alta* or Upper Beira, *Beira-Baixa*, or Lower Beira, and *Beira-Mar*, or Maritime Beira. Except along the coast, the surface is for the most part mountainous,—the highest point, in the Serra de Estrella, being 7524 feet. Besides the Douro, which is far the largest, the Aguada, the Mondego, the Vouga, and the Zezere are the principal rivers. The soil, except in the valleys, is dry and rocky, and large stretches are covered with heath. The principal agricultural productions are maize, wheat, garden vegetables, and fruit. The olive is largely cultivated, the oil forming one of the chief articles of export; and good wine is also produced. In the flat country between Coimbra and Aveiro the marshy land is laid out in rice-fields, or in pastures for herds of cattle and horses. The rearing of sheep is not so well attended to as formerly, except in Upper Beira. In the neighbourhood of Lamego swine are reared in considerable numbers, and furnish the well-known Lisbon hams. There is comparatively little manufacturing industry in the province, with the exception of the production of woollen cloth, which occupies a large part of the population in the district of Castello Branco or Covilhao. Silver and lead ores exist in the mountains, but are neglected. Iron, coal, and marble are worked to some extent, and millstones are quarried in some places. Salt is obtained in considerable quantities from the lagunes along the coast. There is a striking difference of character between the inhabitants of the lower and more elevated regions of Beira, the former being sociable and courteous, if also indolent and lax in morals; while the latter are grave and reserved, hardy and industrious. The principal towns in the province are Coimbra, Vizeu, Aveiro, Omar, and Lamego. The heir-apparent to the throne of Portugal has the title of Prince of Beira.

BEIT EL FAKIH (*i.e. House of the Saint*), an unwalled town in Arabia, in the province of Yemen, 77 miles N.E. of Mocha, and about 17 from the coast, in 43° 23′ E. long., 13° 32′ N. lat. It is situated on a barren, sandy plain, protected against the predatory incursions of the Arabs by a castle, in which the governor resides. It was founded in the 17th century by the inhabitants of the seaboard town of Alafaka, who were led to seek a new settlement from their once famous harbour being rendered useless by coral banks; and it soon became the greatest seat of the coffee-trade in the world. The prosperity of the city was considerably diminished under the Wahabees and Mehemet Ali of Egypt, though even during his domination it is stated to have had 30,000 inhabitants. It is still engaged in the coffee-trade, and also deals in incense, gum, and pearls. Most of the common houses are mere grass-roofed huts, but here and there are ancient stone buildings. The most remarkable of these is the mosque of Akhmed-Ibn-Musa, which is older than the city itself. The principal ports at which the exports are shipped are Lohaya, about 32 miles N.W., and Hodeida, 37 miles S. Population, 8000.

BEJA, a city of the province of Alemtejo, in Portugal, 36 miles S. of Evora. It is surrounded with walls, is the see of a bishop, and contains about 6600 inhabitants, who are for the most part occupied in cultivation, and especially in breeding cattle.

BEJAR, a fortified town of Spain, in the province of Salamanca, situated on the River Cuerpo de Hombre, in a deep and fertile valley of the Sierra de Bejar, about 45 miles S. of the provincial capital. Its streets are narrow, but well paved, and most of the houses are old. The manufacture of cloth is carried on, and there is a considerable trade in cattle at the annual fair. There are saline springs, with a temperature of 104° to 108° F. A ducal family takes its title from the city, and has a palace within its walls. Population, 10,683.

BEKE, CHARLES TILSTONE, a distinguished English traveller, geographer, and Biblical critic, was born in London, October 10, 1800. Educated for the pursuits of commerce, he afterwards studied law for a short time at Lincoln's Inn, but finally devoted himself to the study of historical, geographical, and ethnographical subjects. The first-fruits of his researches appeared in his work entitled *Origines Biblicæ, or Researches in Primeval History*, which was published in 1834. As an attempt to reconstruct the early history of the human race from geological dates, it naturally raised a storm of opposition on the part of those who felt it their duty to defend the traditional readings of the book of Genesis. For about two years (1836 to 1838) Dr Beke held the post of British Consul in Saxony. From that time till his death his attention was devoted to geographical studies, chiefly of Africa and the Nile Valley. Aided by private friends, he visited Abyssinia in connection with the political mission under Major Harris, and explored districts which up to that time had remained unknown to Europeans. The valuable results of this journey, which occupied him from 1840 to 1843, he gave to the world in 1845 in the work entitled *Abyssinia, a Statement of Facts*, &c. Once again, after an interval of more than twenty years, he went to Abyssinia, for the purpose of obtaining from King Theodore the release of Mr Rassam and other British captives. In this he succeeded, but the king afterwards changed his mind and continued to detain the prisoners. In 1848 he made an unsuccessful attempt to explore the Upper Nile; his labour was repaid, however, by a large amount of information about the countries which he traversed. The ardour with which he pursued his chosen path was shown by his undertaking in his seventy-fourth year a journey to Palestine, for the purpose of determining the real position of Mount Sinai. He conceived that it was on the eastern side of the Gulf of Akabah; and his exploration convinced him that his view was right. It has not, however, commended itself to general acceptance. Dr Beke died at Bromley, in Kent, July 31, 1874.

Dr Beke's writings are very numerous. Among the more important, besides those already named, are—*An Essay on the Nile and its Tributaries*, 1847; *On the Sources of the Nile*, 1849; and *The British Captives in Abyssinia*, 1865. He contributed a large number of *Memoirs* and *Papers* to the Royal Geographical Society, the British Association, the Philological Society, the *Athenæum*, the *Archæologia*, the *Edinburgh New Philosophical Journal*, &c., &c. He was a fellow of the Royal Geographical Society, and for his contributions to our knowledge of Abyssinia received its gold medal, and also that of the Geographical Society of France. For his *Origines Biblicæ* the degree of Ph.D. was conferred on him by the University of Tübingen. He was also a fellow of the Society of Antiquaries. In 1870 he received the grant of a pension on the civil list.

BÉKÉS, a market-town of Hungary, formerly a royal free city, and the capital of the county of the same name, situated at the confluence of the White and Black Körös, 14 miles N.N.W. of Gyula, which is now the capital. The inhabitants, principally Calvinists, amount to 22,500, and are chiefly engaged in agriculture and the rearing of cattle. Count Wenkheim has a fine castle in the town, which was at one time strongly fortified. Long. 20° 41′ 37″ E., lat. 46° 46′ 16″ N.

BEKKER, Balthazar, a celebrated Dutch divine, was born in Friesland in 1634. He was the author of several works in philosophy and theology, which from their freedom of thought and critical rationalism excited considerable enmity against him. His most celebrated production was the work entitled *Die Betooverde Wereld*, or *The World Bewitched*, in which he examined critically the phenomena generally ascribed to spiritual agency, and exposed with much force the many absurdities regarding the power of Satan that had become articles of Christian faith. The *odium theologicum* was fiercely roused by this book, and Bekker was deposed from the office of the ministry. He resided at Amsterdam till his death in 1698.

BEKKER, or Wolff, Elizabeth, a Dutch novelist, was born in 1738. She was married to Adrian Wolff, a Reformed clergyman, but is always known under her maiden name. After the death of her husband in 1777, she resided for some time in France, with her close friend, Agatha Deken. She was exposed to some of the dangers of the French Revolution, and, it is said, escaped the guillotine only by her great presence of mind. In 1795 she returned to Holland, and resided at the Hague till her death in 1804. Her novels were written in conjunction with Agatha Deken, and it is somewhat difficult to determine the exact qualities contributed by each. The *Historie van William Levend* (1785), *Historie van Sara Burgerhart* (1790), *Abraham Blankaart* (1787), *Cornelie Wildschut* (1793–96), have been extremely popular. Some of them have been translated into German and French.

BEKKER, Immanuel, a distinguished philologist, was born at Berlin in 1785, and died 7th June 1871. He completed his classical education at the university of Halle under the famous F. A. Wolf, who was accustomed to speak of him as his most promising pupil. In 1810 he was appointed to a professorship in the university of Berlin. For several years, between 1810 and 1821, he travelled in France, Italy, England, and parts of Germany, examining classical manuscripts and gathering materials for his great editorial labours. Some detached fruits of his researches were given in the *Anecdota Græca*, 3 vols., 1814–21; but the full result of his unwearied industry and ability is to be found in the enormous array of classical works edited by him. The most famous are *Plato*, 10 vols., 1814–21; *Oratores Attici*, 7 vols, 1823; *Aristoteles* (the Berlin edition), 4 vols., 1831–36; *Thucydides*, 3 vols., 1821; *Aristophanes*, 3 vols., 1825; *Sextus Empiricus*, 1842. He also edited 24 volumes of the Byzantine historians. Bekker confined himself entirely to textual recension and criticism, and contributed little to the extension of general scholarship. He was well read in the old French literature, particularly that of Provence, and contributed many papers on it to the *Memoirs of the Berlin Academy*.

BEL. See Baal.

BEL, or Belius, Matthias, an Hungarian divine and historian, was born in 1684, and was educated partly at Halle. In 1719 he was made rector of the evangelical Lyceum at Presburg, where he remained till his death in 1749. His great work was the History of Hungary (*Notitia Hungariæ novæ historico-geographica*), 4 vols., 1735–42, which was not completed. Other works devoted to the history of his native country are—*Hungariæ antiquæ et novæ prodromus*, 1723; *Adparatus ad Historiam Hungariæ*, 1735–46. He also wrote on the literature of the Hungarians.

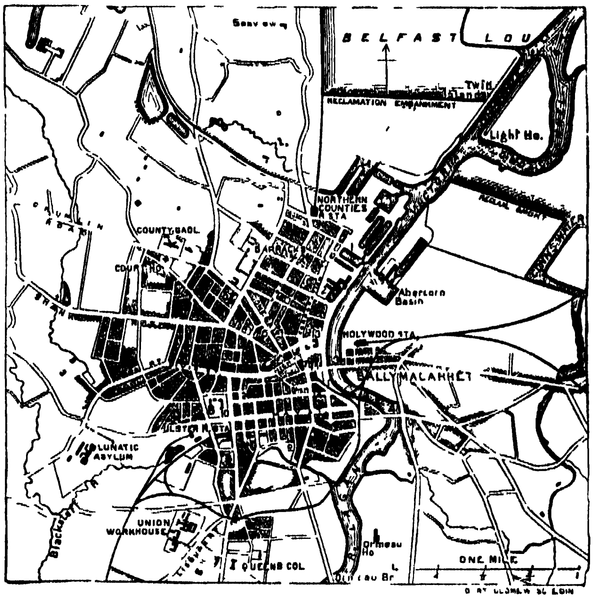
BEL AND THE DRAGON, one of the apocryphal books of the Old Testament. See Apocrypha.

BELA, or Beyla, a town of Baluchistan, capital of the province of Lus, on the north-eastern bank of the River Poorally, 293 miles N. of Khelat. Long. 66° 4′ E., lat. 26° 1′ N. About one-third of the town in the western quarter is encompassed by a mud wall. The streets are narrow, but from the elevated situation of the town, and its rocky site, they are always clean, even in wet weather. The bazaar is very neat. The governor's residence is surrounded by a castellated mud-wall, which also encloses a dome-covered mosque. Population about 5000.

BELBEIS, or Belbeys, a town of Upper Egypt, in the province of Kelyubieh, on the eastern arm of the Nile, 28 miles N.N.E. of Cairo. It was formerly considered the bulwark of the kingdom on that side, and was defended by strong fortifications, but these were suffered to fall into decay till 1798, when Napoleon ordered them to be put in repair. In 1163–4 it was besieged for three months by the Crusaders under Amalric, who at length, in 1168, captured and pillaged it. The present population is not supposed to exceed 5000.

BELEM, a town of Portugal, now regarded as a suburb of Lisbon. See Lisbon.

BELFAST, the chief manufacturing and commercial town of Ireland, a municipal and parliamentary borough, the capital of Ulster, and, since 1850, the county town of Antrim, in which, with the exception of the large suburb of Ballymacarret on the other side of the river, it is



1 Prince's Dock	6. St. Ann's Church.	11. Linen Hall.
2. Clarendon Dock.	7. St. George's Church.	12 Commercial Bdgs.
3. Queen's Bridge.	8 Christ Church.	13. Custom House.
4. Albert Bridge.	9. St. Malachi's Cathed.	14. Town-Hall
5. Trinity Church.	10. Academical Institute.	15. Central Rail Sta.

mainly comprised. It is situated in lat. 54° 36′ 8·5″ N and long. 5° 55′ 53·7″ W., at the mouth of the Lagan, which flows into Belfast Lough (Carrickfergus Bay), and is built on an alluvial deposit and land reclaimed from the sea, the greater portion of which is not more than 6 feet above high-water mark. It was thus for a long period exposed to occasional inundations, and was somewhat subject to epidemics; but its situation, improved by drainage, has become more healthy, while the environs are agreeable and picturesque.

The etymology of the name and the origin of the town are equally uncertain, and there is not a single monument of antiquarian interest upon which to found a conjecture. About the beginning of the 16th century Belfast is described as a "town and fortress," but it was in reality a mere fishing-village in the hands of the house of O'Neil. This sept had all along been opposed to the English, and had forfeited every baronial right; but in 1552 Hugh O'Neil of Clandeboye promised allegiance to the reigning monarch, and obtained the castle of Carrickfergus, the town and fortress of Belfast, and all the surrounding lands. His turbulent successors having been routed by the English, the town and fortress fell into the hands of Sir Thomas Smyth, a favourite of Queen Elizabeth, but were afterwards forfeited by him to the Lord-Deputy Sir Arthur Chichester, who, in 1612, was created Baron Chichester. At this time the town consisted of about 120 houses, mostly built of mud and covered with thatch, while the castle, a two-storied building, was roofed with shingles. In 1632 Thomas Wentworth, Earl Stafford, was appointed first lord-deputy of Ireland, and Belfast soon shared largely in the benefits of his enlightened policy, receiving, among other favours, certain fiscal rights which his lordship had purchased from the corporation of Carrickfergus. Two years after the rebellion of 1641 a rampart was raised round the town, pierced by four gates on the land side. In 1662, as appears by a map still extant, there were 150 houses within the wall, forming five streets and as many lanes; and the upland districts around were one dense forest of giant oaks and sycamores, yielding an unfailing supply of timber to the woodmen of Carrickfergus.

Throughout the succeeding fifty years the progress of Belfast surpassed that of most other towns in Ireland. Its merchants, in 1686, owned forty ships, of a total carrying power of 3300 tons, and the customs collected were close upon £20,000. When King William arrived at Belfast in 1690 there were only two places of worship in the town, the old corporation church in the High Street, and the Presbyterian meeting-house in Rosemary Lane,—the Roman Catholics not being permitted to build their chapels within the walls of corporate towns.

At the commencement of the 18th century Belfast had become known as a place of considerable trade, and what was then thought a handsome, thriving, and well-peopled town, with many new houses and good shops. During the civil commotions which so long afflicted the country, it suffered less than most other places; and it soon afterwards attained the rank of the "greatest town for trade in the north of Ireland." James Blow and Co. introduced letterpress printing in 1696, and in 1704 issued the first copy of the Bible produced in the island. In September 1737, Henry and Robert Joy started the Belfast *News Letter*, which not only still maintains its existence, but has long been at the head of the Irish Conservative press. Twenty years afterwards the town contained 1800 houses and 8549 inhabitants, 556 of the latter being members of the Church of Rome. It was not, however, till 1789 that Belfast obtained the regular communication, which towns of less importance already enjoyed, with Dublin by stage coach,—a fact which is to be explained by the badness of the roads and the steepness of the hills between Newry and Belfast.

The increased freedom of trade with which Ireland was favoured, the introduction of the cotton manufacture by Robert Joy in 1777, the establishment in 1791 of ship-building on an extensive scale by William Ritchie, an energetic Scotchman, combined with the rope and canvas manufacture already existing, supplied the inhabitants with employment, and increased the demand for skilled labour. The population now made rapid strides as well by ordinary extension as by immigration from the rural districts. At the close of last century there were about 20,000 inhabitants in the borough, and this total had risen in 1821 to 37,277, in 1831 to 53,287, in 1841 to 70,447, in 1851 to 87,062, in 1861 to 121,602, and in 1871 to 174,412—males 79,815, and females 94,597. In 1875 the population is estimated at 200,000. At the last census the following were the religious professions of the population, viz., Presbyterian, 60,249; Catholic, 55,675; Episcopal, 46,423; Methodist, 6775; Unitarian, 1498; and various, 3892. The number of persons who could read and write at the same date was 95,986; who could read only, 71,700; and who were illiterate, 46,726, or about 27 per cent. of the whole. The number of houses in 1871 amounted to 29,918, viz., inhabited, 27,961; uninhabited, 1761; and building 196.

Belfast Lough is exceedingly picturesque, whether entered by the Antrim or by the Down side of the channel. The outer harbour is one of the safest in the kingdom, great improvements having been made within the last thirty years on the more immediate entrance to the port. The course of the Lagan, which runs past the quays and down to Gramoyle, was originally most tortuous and somewhat difficult to navigate; but, about 1840, the late William Dargan was employed to make a straight cut from the lower part of the harbour and to deepen the channel, so that ships of large draught can be brought to the quays, which extend for about a mile below Queen's Bridge on both sides of the river. There are also seven extensive docks and tidal basins supplied with the necessary conveniencies for the shipping. The following table of vessels entered inwards shows the increase of shipping frequenting the port:—

Year.	No. of Vessels.	Tonnage	Year.	No. of Vessels.	Tonnage.
1728	370	9,180	1845	3655	445,537
1786	770	34,287	1855	5211	768,505
1805	810	64,585	1861	6737	902,578
1825	2060	183,141	1871	8213	1,223,821
1835	2950	290,769	1873	8117	1,397,107

The exports from Belfast being largely conveyed by steamer to London, Liverpool, and Glasgow, and thence trans-shipped to their destinations, do not appear in the Board of Trade returns, as only the direct business with foreign countries, which does not reach any considerable amount, is registered in those tables. Thus other ports get credit for business which really belongs to Belfast. The best illustration of this is afforded by the Board of Trade returns for 1858. Belfast is there stated to have exported goods that year to the amount of £9,344, while the actual sum was £8,569,504. In 1810 the total value of exports was £2,904,820, and in 1835 £4,341,794; in 1852 the amount was £6,573,198, and for 1866 it ran up to £11,915,000. For some years past no official data have been published on this subject, but it may be safely estimated that the gross value of the exports from Belfast exceeds £20,000,000 annually.

The amount of customs and excise collected at the port in 1762 was £32,900, and in 1810 the sum was £428,174. As trade increased with London and Liverpool, a large share of the duties on goods disposed of in Belfast was paid to the merchants of those ports. In 1821 the customs amounted to £306,243, and in 1848 to £376,767. The customs paid in Belfast in 1851 reached £369,415, which, added to that paid in London and Liverpool (£184,750), made a total of £554,165. During the year 1874 the duty paid in Belfast on tea, wine, spirits, and tobacco, amounted to £1,215,191.

For nearly a century past the flax manufacture of Ulster

has been gradually concentrating itself in Belfast. The introduction there in 1830, by T. and A. Mulholland, of machinery for the spinning of linen yarn, was followed by a rapid extension of the industry, and in 1841 there were 240,000 spindles at work. The succeeding ten years showed still greater increase. In 1851 there were 561,000 spindles in operation throughout Ireland, 630,000 in 1861, and 903,000 in 1871, of which about four-fifths had been set up in Belfast. Linen yarns from Belfast form a considerable item in the total export of manufactures. For some time after the trade was started, the average annual export was only about 1,000,000 ℔ weight; but in 1850 five times that quantity was despatched; in 1862, 15,685,600 ℔, and in 1864, 24,075,520 ℔.

The weaving of linen by means of power-looms, though long carried on in Dundee, Leeds, and other great seats of manufacture, is of comparatively recent introduction into Belfast,—being hardly known there five-and-twenty years ago. In 1859, however, there were 3000 looms engaged; in 1866 there were 10,500, and that number has now (1875) increased to about 12,500. A number of these have been fitted up for the damask trade, but the great proportion are used for plain linens, "sets" of which of great fineness are worked. The extent of the linen trade may be indicated by the number of persons employed, which amounted in 1871 to 8507, or about 5 per cent. of the population.

Cotton-spinning, which at one period formed a most extensive industry in Belfast, has greatly fallen off,—nearly all the mills having been converted to the spinning of flax.

The enterprise of the citizens of Belfast was well supported by the liberal system of tenure for building purposes granted by the late Lord Donegall and his predecessors. Sites for mills, factories, and other public works were obtained on very reasonable terms, and for all religious and charitable objects those lords of the soil bestowed ground free of rent. In 1851 the places of worship in Belfast open for service belonged—11 to the Episcopalians, 21 to Presbyterians, 8 to Wesleyans, and 4 to Roman Catholics. Since then there has been a large increase in the number; and there are now 19 Episcopalian churches, 28 Presbyterian, 16 Wesleyan Methodist, 6 Roman Catholic, 3 Unitarian, and 7 or 8 belonging to various other sects.

The River Lagan is crossed by three bridges, of which the principal is the Queen's Bridge, opened in January 1843, and built on the site of the Old Long Bridge, which dated from 1686. Like most modern towns which have rapidly risen through commerce and manufactures, Belfast cannot boast of many architectural beauties. It would seem as if its people had been too deeply absorbed in the bustle of business to think of æsthetic superfluities. More recently, however, a higher style of building has been adopted; and some of the warehouses and shops show great taste in design and finish of workmanship.

The public buildings most worthy of notice are the White and Brown Linen Halls, the Corn Exchange, the Commercial Buildings, the Museum, the Albert memorial monument, the Northern, Belfast, Ulster, and Provincial Banks, the new theatre, the town-hall, and the range of buildings containing the offices for the customs, the inland revenue, and the postal departments. The county lunatic asylum is in the suburbs of the town; and in the neighbourhood of Queen's College there is an extensive and well-kept botanic garden.

The chief educational establishments are the Royal Academical Institution, the Queen's College (built of brick in the Tudor style and opened in 1849), the Government School of Design, the General Assembly's College, the Catholic Institute, and the Wesleyan Institute; and altogether, in proportion to its extent, no town in the kingdom is better supplied with educational appliances than Belfast.

Belfast is governed by a corporation of 40 members—a mayor, 10 aldermen, and 29 councillors; and all matters connected with the docks and shipping are under the harbour commissioners, an important body elected by the ratepayers. The borough returns two members to parliament, and the county assizes are held there, as well as the quarter sessions, recorder's court, and petty sessions.

BELFORT, Béfort, or Bedfort, a second-class fortified town of France, was formerly in the department of Upper Rhine, and capital of an arrondissement, but since the peace of 1871, it has given name to a separate territory not as yet incorporated with any department. It is situated on the left bank of the Sauvoureuse, 38 miles S.S.W. of Colmar, at the intersection of several important roads and railways, by which it maintains a considerable trade with Germany and Switzerland. It contains a handsome church,—St Cristophe, erected in the 18th century,—a college, a large public library, a synagogue, a theatre, and an hospital. There are several iron foundries, and iron-wire and tin-plate factories; and the manufacture of hats and leather is also carried on. Belfort, however, derives its chief importance from the citadel and entrenched camp, which render it one of the most valuable military posts on the French frontier, defending as they do the entrance into the country through the opening between the Vosges and the Jura. The citadel dates from the 13th century, and the town itself was first regularly fortified in 1688 by Vauban. In November 1870 siege was laid to the place by the German forces, but the French garrison managed to hold out till the 16th of February 1871, when they capitulated with the sanction of the Government, and marched out with the honours of war. The conquerors finally evacuated the place in July 1871. At the census of 1872 the population of the town was found to be 8014.

BELGÁM [Belgaum], a district of British India in the Bombay Presidency, extending from 15° 30′ to 16° 15′ N. lat., and 74° to 76° 30′ E. long. It is bounded on the N. by the state of Miraj, on the N.E. by the Raládgi collectorate, on the E. by the states of Jámkhandi and Mudhol, on the S. by the collectorates of Dhárwár and Kánará, on the S.W. by the Portuguese territory of Goa, and on the W. by the states of Sáwantwári and Kolhápur. The principal rivers, none of which are navigable, are the Krishná, flowing through the northern; the Ghátaprabhá, through the centre; and the Máláprabhá, through the southern portion of the collectorate. To the N. and E. the country is open and well cultivated, but to the S. it is intersected by spurs of the Sahyádri range, thickly covered in some places with forest. Area, 4591 square miles. Population, 938,750 souls, or 204 to the square mile; 57 per cent. Hindus, 7·5 per cent. Mahometans, 5 per cent. Buddhists, ·5 Christians, and ·01 Parsis. Maráthi and Kanarese are both spoken, the former chiefly in the W. and S. of the district, and the latter in the N. and E. The chief occupation of the people is agriculture, the other industries being spinning and weaving, manufactures in wood and metals, pottery, and shoemaking. There is also a considerable trade in cloth and silk. The principal agricultural products are rice, tawári, rági, wheat, bájra, sugar-cane, barley, and pulses. Tobacco is cultivated to a small extent. The entire revenue of the district amounts to £233,371, of which £179,321 is derived from the land revenue, and £17,597 from the local fund cess. Of the remainder £15,444 is derived from stamps, £14,996 from excise, assessed taxes yield £2344, and forests £3669. Of a total area of 4591 square miles, 1894·63 square miles are returned as cultivable, and 1729·7, or 37½ per cent. of the

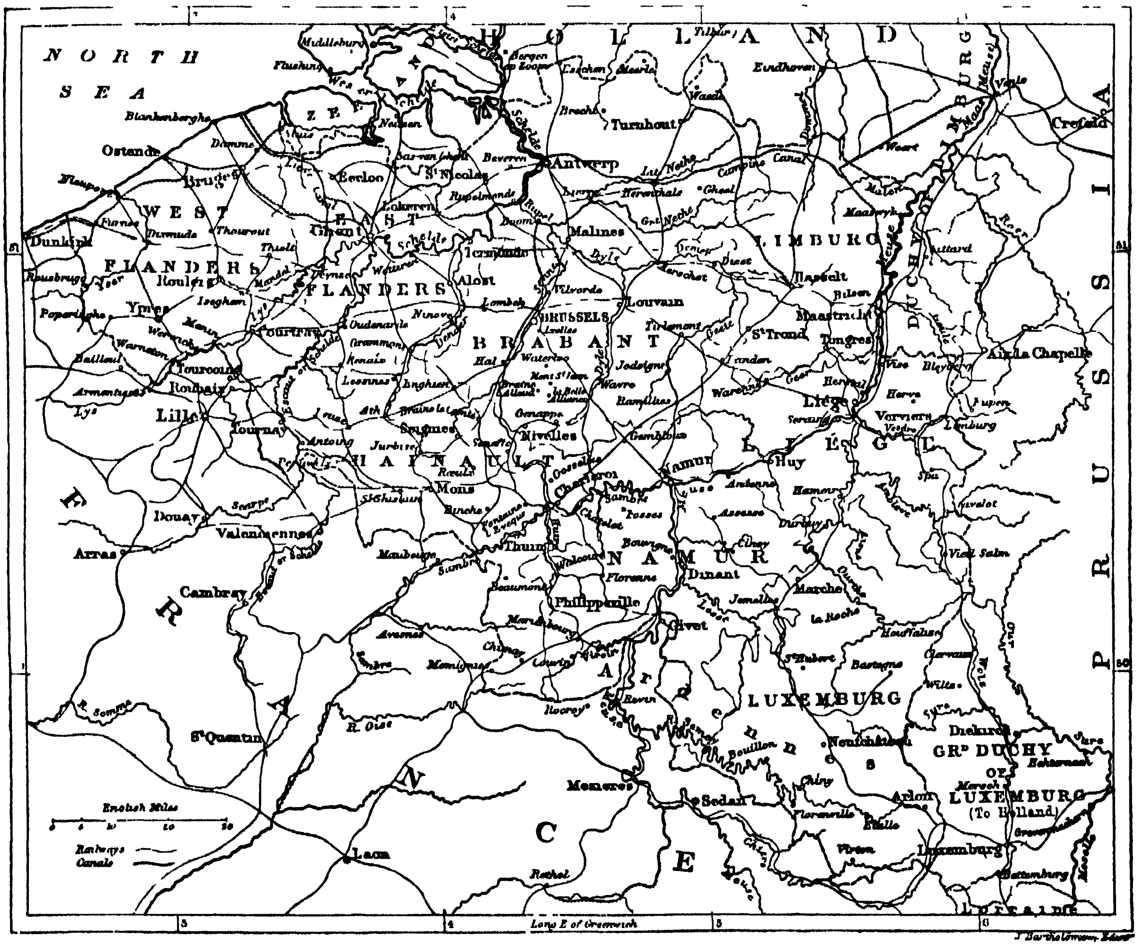
total area, are actually under cultivation. The last settlement of the land revenue was made for a period of thirty years at various times between 1848 and 1864. The total imperial expenditure in the district amounts to £98,097. The following towns have a population of more than 5000 inhabitants:—Belgaum, 26,947; Gokak, 12,612; Athani, 11,588; Nipáni, 9371; Temkanmardi, 5296; Hougal, 9001; Sankeshwar, 8905; Sawadati, 8180; Murgod, 7181; Ketur, 7166; Sádalgi, 6863; Mánoli, 6232; Chikadi, 6184; Nandighai, 5748; Hukéri, 5364; and Konganoli, 5143. Municipalities have been established in the first five of these towns, the necessary revenue being raised by *octroi* dues, except in the case of Temkanmardi, where a house tax has been levied. The district contains 113 schools, with an attendance of 7624 pupils, or 0·8 of the entire population. Of the total number of schools, 2, with an attendance of 198 pupils, are private institutions, receiving Government aid. There is a stipendiary police of 684 men. The Kurirs, a wandering and thieving tribe, the Kamais, professional burglars, and the Báruds, cattle-stealers and highwaymen, are special criminal classes. Of these the Báruds are the most troublesome. The district of Belgám was ceded to the East India Company by the Peshwá, under the treaty of June 1817, for the maintenance of a subsidiary force to be provided by the British Government.

BELGIUM

Extent and boundaries.

BELGIUM (Fr. *Belgique*, Ger. *Belgien*) is one of the smaller of the European states, among which it ranks 16th in point of area and 8th according to population. It lies between lat. 49° 30′ and 51° 30′ N., and long. 2° 32′ and 6° 7′ E.; and is bounded on the N. by Holland, E. by Dutch Limbourg, Luxembourg, and Rhenish Prussia, S. and S.W. by France, and N.W. by the North Sea. It is somewhat triangular in form, the longest side—that which

See also map of Holland



Sketch-Map of Belgium.

adjoins France—being 384 miles in length. The length of its other boundaries are,—towards Holland 268 miles, Germany 59, Luxembourg 80, and the North Sea 41. Its greatest length from N.W. to S.E. (from Ostend to Arlon) is 174 miles, and its greatest breadth from N. to S. 105. It has an area of 2,945,593 hectares, equal to 7,278,968 English acres, or 11,373 square miles,—being about one-eighth of the area of Great Britain. This country is divided into nine provinces,—Antwerp in the N., West and East Flanders and Hainault in the W., Namur in the S., Luxembourg in the S.E., Liége and Limbourg in the E., and Brabant in the centre.

Physical features.

Belguim is in general a very flat country, having few elevations, and these rarely exceeding 2000 feet in height. They are principally to be found in the E. and S.E., while the N. and N.W. parts of the country bear a considerable resemblance to Holland. The elevations of Belgium take their rise in France, and extend generally in a N.E. direc-

tion. A chain proceeding from the neighbourhood of the sources of the Saone separates the waters of the Meuse from those of the Moselle, passes Arlon and Neufchateau, then extends in a north-eastern direction towards Bastogne, and finally enters Prussia. A branch of this chain goes off at Neufchateau, proceeds northward towards Liége, passes St Hubert, and separates the Ourthe from the Meuse. A part of the Ardennes also extends into Belgium, and separates the basin of the Meuse from that of the Scheldt. It proceeds in a north-eastern direction, passing Fontaine l'Evêque, Gembloux, Ramillies, and Tongres, then, gradually decreasing in height, it turns northward to Asch, and afterwards N.W. to Hechtal, Lommel, and Turnhout. A series of heights on the frontier of France, near Chimay, extends in a N.W. direction towards Namur, and separates the Meuse from the Sambre.

The provinces of Liége, Luxembourg, and Namur present the greatest irregularities of surface. This part of the country is intersected by numerous ravines and streams with steep and rocky banks, by deep valleys, and by ridges of hills, which often have precipitous and rocky escarpments. The vegetation here is of a very poor and languid character. The greater part of the region is covered with dense forests, marshy and uncultivated plateaus or poor pasture land, and corn is very rarely cultivated. Descending towards the coast the forests become less extensive; and rye, oats, and potatoes take the place of the pasture land. In the western and north-western provinces are extensive and well-watered plains, which, from their great fertility and the high state of their cultivation, are the boast of the Belgians and the admiration of strangers.

In the provinces bordering on the sea the land is in some places so low as to require to be protected from inundation by dikes. These parts are called *polders*. Numerous places along the banks of the rivers are also protected by embankments; these are called *interior polders*. About a sixtieth part of the kingdom (50,000 hectares, or 193 square miles) is thus artificially gained from the sea and rivers.

The coast of Belgium is said to be undergoing a change similar to that of Scandinavia,—in some parts a gradual elevation, and in others a gradual depression. Nieuport is said to be on the axis of this change, from which, northward to the mouth of the Scheldt, the sea is continually gaining upon the land, while southward to Pas de Calais it is losing.

The principal rivers are the Scheldt, Meuse, and Yzer, with their tributaries. The Scheldt is navigable during its entire course through Belgium, and has a general direction from S.W. to N.E., passing through the province of Hainault, along the eastern boundary of West Flanders, traversing East Flanders, and finally forming the boundary between the provinces of East Flanders and Antwerp. Its entire length through Belgium is 108 miles. The Meuse has a course nearly parallel to that of the Scheldt, traversing the provinces of Namur, Liége, and Limbourg. It is 115 miles in length, during the whole of which it is navigable. The small river of Yzer, which enters the sea at Nieuport, is navigable for about 26 miles. The navigable rivers connected with the Scheldt are,—the Dyle, which after receiving the Nethe at the village of Rumpst, takes the name of Ruppel, and joins the Scheldt nearly opposite to Ruppelsmonde; the Great and Little Nethe, which after their junction take the name of Nethe, and fall into the Dyle; the Demer, also an affluent of the Dyle; the Dender, which enters the Scheldt at Dendermonde; the Durme, which joins it near Thielrode; and the Lys at Ghent. The entire navigable length of these streams is 230 English miles. The navigable rivers of the Meuse are the Amblere and the Vesdre, affluents of the Ourthe; the Ourthe, which joins the Meuse at Liége; and the Sambre, which joins it at Namur. The navigable length of these is 142 miles. The small river of Yperlee, which joins the Yzer, is navigable for about 9 miles. The other streams are the Senne, the Haine, the Semoy, and the Lesse.

Besides these navigable rivers, Belgium has a number of canals for inland navigation, some of which are also used for irrigation. They are twenty-nine in number, and their entire length is 605,440 metres, or 376 English miles. The principal of these are the canals—from Bruges to Ostend, from Brussels to Charleroi, from Bocholt to Herenthal, from Brussels to Willebroeck, from Ghent to Bruges, from Liége to Maestricht, from Maestricht to Bois-le-Duc, from Pommeroeul to Antoing, from Plasschendaele to Nieuport, the Louvain canal, the Lieve, and the Moevaert. Each of these canals is upwards of 12 miles in length, and the longest, that from Brussels to Charleroi, upwards of 46 miles. The entire length of the river and canal navigation of Belgium is 1006 English miles. Canals.

Belgium possesses a number of mineral springs, the principal of which are the hot springs of Chaudfontaine, situated about five miles from Liége, and the mineral spring of Tongres; but the most celebrated waters are those of Spa. The ferruginous springs of Huy were formerly in considerable repute, but are now little used.

The climate of Belgium is similar to that of England, but is a little colder in winter and hotter in summer. In the south-eastern parts the atmosphere is more pure and bracing than in the lower parts towards the N.W., where it is frequently damp and hazy. Frost rarely appears before the middle of October or after the middle of April. Observations made at Brussels from 1833 to 1872 give the mean annual temperature as 50°·6 Fahr.,—the mean maximum being 57°·2, and the mean minimum 44°·1 Fahr. During that period there were no frosts in the five months from May to September inclusive, and snow fell only eight times in May and 4 times in October. The average number of foggy days annually, from 1833 to 1862, was 60, and with thunder 15. The annual average of days on which rain fell was 197, and the quantity of rain 28·04 inches, or 3 inches less than the rainfall at London. Climate.

The population of Belgium in 1831 was 3,785,814; in 1840, 4,073,162; in 1850, 4,426,202; in 1860, 4,731,957, and in 1873, 5,253,821, being 2,645,147 males and 2,608,674 females. The following table shows the population of the different provinces in each of the years 1831 1850, and 1873 (31st December):— Population.

	1831.	1850.	1873.
Antwerp	349,942	420,556	513,543
Brabant	561,828	734,617	922,468
East Flanders	742,973	783,450	854,366
West Flanders	608,226	631,137	682,921
Hainault	613,179	733,740	932 036
Liége	375,030	467,843	623,165
Limbourg	160,090	188,198	202,922
Luxembourg	160,762	192,588	206,069
Namur	213,784	274,073	316,331
	3,785,814	4,426,202	5,253,821

The principal towns are – Brussels, with 180,172 inhabitants; Antwerp, 141,910; Ghent, 128,424; Liége, 113,774; Bruges, 48,113; Verviers, 38,875; Tournay, 31,923; Malines, 38,540; Louvain, 32,314.

Belgium is the most densely populated country of Europe, having on an average 178 inhabitants to the square kilometre, which is equivalent to 461 to the square mile. The density differs greatly in the several provinces, being as high as 285 per square kilometre in East Flanders, 281 in Brabant, and 250 in Hainault; and as low as 86 in Namur, 84 in Limbourg, and 47 in Luxembourg. The general census of 1866 gives 134,001 as under one year of age; 549,077 between one and five years, and 494,332 between five and ten; while 299,711 were from sixty to seventy, 115,216 from seventy to eighty, 23,890 from eighty to ninety, 1292 from ninety to a hundred, and 12 a hundred and upwards. The number of

unmarried persons was 3,011,566, of married persons 1,528,543, of widowers and widows 287,724. As regards their places of birth, 3,348,506 had been born in the same commune in which they lived; 1,381,231 had been born in another commune of the same province; 288,672 had been born in another province of the kingdom, 13,044 in the ceded districts of Luxembourg or Limbourg, 26,435 in other parts of Holland, 32,021 in France, 20,701 in Germany, 3003 in England, and 2892 in other countries. In 1873 the births were 170,708, being 87,128 males, and 83,580 females, or 104 males to 100 females,—giving one birth to every 30·3 of the population, and 151 births to a hundred deaths. Of the births 158,585 were legitimate and 12,123 illegitimate, or 13 legitimate births to 1 illegitimate. The proportion, however, varies much in the different provinces, being 7·5 to 1 in Brabant, and 37 to 1 in Luxembourg. The number of marriages that took place was 40,598, and of deaths 112,873. Of the latter, 24,282 were under one year, and 16,730 between one and five years of age; 315 males and 62 females were by suicide, 2068 were from accidents, and 69 were murdered. The immigrations were 15,792, and the emigrations 7981.

Languages. The languages spoken in Belgium are French or Walloon (a dialect of the ancient French), and Flemish or Dutch. French is the language of the upper and educated classes, and is generally understood even in the Flemish parts of the kingdom. In 1866 those speaking French or Walloon amounted to 2,041,784; Flemish or Dutch, 2,406,991; French and Flemish, 308,361; German, 35,356; French and German, 20,448; Flemish and German, 1625; and the three languages, 4966. The French or Walloon is the prevailing language in the provinces of Hainault, Liége, Luxembourg, and Namur; the Flemish or Dutch in Antwerp, Brabant, the two Flanders, and Limbourg.

Government. Since the formation of Belgium into an independent state, the Government has taken a laudable interest in all that concerns the advancement and happiness of the people; and not being trammelled by a respect for old laws or useless customs, it has adopted, as far as possible, the most improved systems of other countries. The whole system of government is based upon the broadest principles of rational freedom and liberality. All power emanates from the people, and can be exercised only according to law. The people are upon a strict equality in the eye of the law; personal liberty is guaranteed to all, as well as entire freedom in opinion and in religious worship. All the religious sects are endowed by the state, and large grants are also given annually for educational and charitable purposes. Home is inviolable, nor can any one be deprived of his property unless for the good of the state and for a suitable indemnity. Justice is open to all, as well as the means of education, and the benefits of the public charities. The press is free, and civil death is abolished. Any one may address petitions to the public authorities signed by one or more persons. Trial by jury is established for all criminal and political charges, and for offences of the press. The contents of letters are inviolable, and the post-office is responsible for all letters committed to it.

The government is a constitutional representative and hereditary monarchy. The legislative power is vested in the king, the chamber of representatives, and the senate. The judicial power is exercised by fixed tribunals, freed from all authoritative influences, judging publicly, and assigning reasons for their decisions. Affairs exclusively provincial or communal are managed by the provincial or communal councils.

King. The royal succession is in the direct male line in the order of primogeniture, to the exclusion of females and their descendants. The king's person is declared sacred, and his ministers are held responsible for the acts of the Government. No act of the king can have effect unless countersigned by one of his ministers, who thus becomes the responsible party. The king convokes, prorogues, and dissolves the chambers, and makes rules and orders necessary for the execution of the laws, but has no power to suspend or dispense with the execution of the laws themselves. He nominates to civil and military offices, and commands the sea and land forces. He declares war, and concludes treaties of peace, of alliance, and of commerce,—communicating the same to the chambers as far as may be consistent with the interest and safety of the state. He sanctions and promulgates the laws, and has the power of remitting or reducing the punishments pronounced by the judges, except in the case of his ministers, to whom he can extend pardon only at the request of one of the chambers. In default of male heirs the king may nominate his successor with the consent of the chambers. The regency can only be conferred upon one person, and no change in the constitution can be made under his rule.

The people are represented in the Legislature by the Chamber of Representatives and the Senate, the members of which are chosen by the people. Each chamber determines the manner of exercising its own powers, and every session nominates, its president and vice-presidents, and forms its *bureau*. No petition can be presented personally; and every resolution is adopted by the absolute majority, except in some special cases, when two-thirds of the votes of the members are required to be favourable; in the case of an equality of votes the proposition is thrown out. The chambers meet annually in the month of November, and should sit for at least forty days; but the king has the power of convoking them on extraordinary occasions, and of dissolving them either simultaneously or separately. On dissolution a new election must take place within forty days, and a meeting of the chambers within two months. An adjournment cannot be made for a period exceeding one month without the consent of the chambers.

Chamber Representatives. The Chamber of Representatives is composed of deputies chosen directly by the people paying a certain amount of direct taxes. The number of deputies is fixed according to the population, and cannot exceed one member for every 40,000 inhabitants; at present they amount to 124. To be eligible for membership it is necessary to be a Belgian by birth or to have received the grand naturalization, to be in the possession of the civil and political rights of the kingdom, to have attained the age of twenty-five years, and to be resident in Belgium. The members not residing in the town where the chamber sits receive, during the session, an indemnity of 200 florins (£16, 13s. 4d.) each per month. The members are elected for four years, one-half going out every two years, except in the case of a dissolution, when a general election takes place. This chamber has the parliamentary initiative and the preliminary vote in all cases relating to the receipts and expenses of the state, and to the contingent of the army.

Senate. The electors of the Chamber of Representatives have also the nomination of the members of the Senate. To be eligible as a senator it is necessary to be a Belgian by birth or to have received the grand naturalization, to be in the enjoyment of civil and political rights, to be domiciled in Belgium, to be forty years of age, and to pay at least 1000 florins (£84) of direct taxes. In those provinces where the number of those paying 1000 florins of taxes does not amount to one in every 6000 inhabitants, this proportion is made up by those paying the highest amount below that sum. The permanent deputations of the provincial councils annually prepare a list of those who are eligible to the Senate. In 1874 the number of these was 453. At the age of eighteen the heir-presumptive to the throne has a seat in the Senate, but he has no voice in its deliberations till he attain the age of twenty-five. The senators receive no indemnity. They are elected for eight years, one-half going out every four years, except in the case of a dissolution. The Senate is composed of half as many members as the Chamber of Representatives, the number at present being 62.

In order to be a general elector it is necessary to be a Belgian by birth or to have received the grand naturalization, to be twenty-one years of age, and to pay direct taxes to the amount of at least 20 florins (33s. 4d.) In 1874 the total number of general electors was 111,135, or at the rate of 21·15 per 1000 of the population.

Ministers. The king appoints and dismisses his ministers at pleasure. No member of the royal family can be a minister, nor any but a Belgian, or one who has received the grand naturalization. Ministers have a right of admission to the chambers, and may demand a hearing; but they have no voice in the deliberations unless they are members. The chambers can at any time require the presence of the ministers. No act or writing by the king can free a minister from responsibility. The Chamber of Representatives has the power of accusing the ministers, and of bringing them before the court of cassation, which alone has the right of judging them, in all cases of offences committed in the exercise of their functions. There are six ministers, viz., of foreign affairs, of the interior, of justice, of finance, of war, and of public works.

Naturalization. Naturalization is of two kinds, the one conferring on the foreigner all the civil and political rights belonging to a Belgian, with certain exceptions specified by law, such as the right to vote in the choice of members for the legislative chambers or of sitting there; to obtain these the *grand naturalization* is requisite. The registration-fee for the former is 500 francs; for the latter, 1000. Since 1831 only 47 have received the grand naturalization and 1527 the ordinary.

Divisions. For civil purposes the provinces are divided into 26 arrondissements, 204 justice-of-peace cantons, and 2528 communes; and for military purposes, into 41 arrondissements, 303 military cantons, and 2568 communes.

Provincial government. In each province is a governor named directly by the king, for the purpose of superintending and securing the due execution of the laws, and a provincial council, composed of Belgian citizens at least twenty-five years of age, residing in the province, and in the enjoyment of civil and political rights. The number of members of each provincial council is made to depend upon the population, and varies in the different provinces from one for every 11,500 of the population in Brabant and Hainault, to one for every 5000 in Limbourg and Luxembourg. Each canton, however, is entitled to be represented by at least one member, and the number of members for each canton depends upon the population according to the scale fixed for the province. The total number of members in 1874 was 559,—Antwerp council having 58; Brabant, 73; East Flanders, 80; West Flanders, 69; Hainault, 76; Liége, 67; Limbourg, 40; Luxembourg, 41; and Namur, 55. The electors of the members of the provincial councils were formerly the same as the electors of the legislative chambers, but in 1872 the provincial franchise was lowered, and the number of electors in 1874 was 219 619, or 41·80 to 1000 inhabitants. A provincial elector requires to be a Belgian or to have received naturalization, and to pay taxes to the amount of 20 francs (16s.) Members of the chambers, governors, and persons in the employment of the state or province, are ineligible as councillors. The councils have an annual session of not more than four weeks; but the king can convoke them on extraordinary occasions. Those not residing in the provincial capital receive an indemnity during the session. Each provincial council appoints a permanent deputation for conducting business in the interval between the sessions, particularly in matters requiring immediate attention. It is composed of six members chosen for four years, one-half going out every two years.

These councils are of the highest importance to the country. They watch over the interests of their several provinces, prepare the budgets, direct taxation, and superintend public works. They give a healthy impulse to agriculture, trade, and commerce; direct the construction of roads, canals, and bridges; and extend the benefits of education and religion throughout the country. The communes have the power of appeal to the king if they consider themselves aggrieved by any of the acts of the provincial council, or of the permanent deputation.

Communal government. Matters exclusively communal are managed by communal councils. The councillors are Belgian citizens in the full enjoyment of civil and political rights, and, except in some special cases, resident in the commune. They are elected for six years, one-half going out every three years. The number of the councillors is from 7 to 31, in proportion to the population of the commune, which varies from under 1000 to upwards of 70,000 inhabitants. Communal electors require to be Belgians or to have received naturalization, and to pay taxes to the amount of 10 francs (4s.) The total number of electors in 1874 was 347,441, being 66·13 per 1000 of the population. Communes with less than 20,000 inhabitants have two aldermen, and those having more than that number have four. There is also in each commune a burgomaster, who, as well as the aldermen, is chosen by the king from among the members of the communal council

Religion. Full liberty is guaranteed to all in the exercise of the public or private rites of their worship; nor does the state interfere in any way in matters of religion, except where the public safety may be concerned or the laws infringed. Almost the entire population of Belgium is Roman Catholic, there being only about 15,000 Protestants and 3000 Jews. The ministers of each denomination are paid by the state, -- the amount so paid in 1873 being 4,648,757 francs, or £185,950, of which Roman Catholics receive 4,568,200 francs, Protestants 69,336, Jews 11,221.

Roman Catholics. The kingdom is divided into six Roman Catholic dioceses,—the archbishopric of Malines, and the bishoprics of Bruges, Ghent, Liége, Namur, and Tournay. The archbishopric has three vicars-general, and a chapter of twelve canons; and each of the bishoprics, two vicars-general, and a chapter of eight canons. In 1873 there were 156 deaneries, 233 rectories, 2788 chapels of ease, 148 public chapels, and 1745 vicariates.

The temporal affairs of the churches are managed by a vestry-board and a board of wardens. There is an ecclesiastical seminary in each diocese, and scholarships are annually given by the state to certain of the students upon the presentation of the chief of the diocese. The state also contributes to the salaries of the professors by an annual grant to each of the seminaries, except that of Liége which has sufficient funds otherwise. The provinces are bound to provide and maintain suitable buildings for these seminaries. There are a number of religious houses in Belgium for males and females, whose lives are spent in pious contemplation, teaching, and visiting the sick. The number of these houses in 1866 was,—for males 178, and for females 8144; the number of persons in the former was 2991, and 15,205 in the latter.

Protestants. The Protestant Evangelical Church is under a synod, composed of the clergymen of the body and a representative from each of the churches. It sits in Brussels once a year, when each member is required to be present, or to delegate his powers to another member. The Anglican Church has eight pastors and as many chapels in Belgium, —three in Brussels and one in each of the towns Antwerp, Bruges, Ghent, Ostend, and Spa.

Jews. The Jews have a central synagogue at Brussels, three branch synagogues of the first-class at Antwerp, Ghent, and Liége, and two of the second-class at Arlon and Namur. The civil and religious affairs are conducted by a

consistory of nine members, six of whom are appointed by the central, and one by each of three first-class synagogues. The grand rabbi, who is at the head of this body in Belgium, is, *ex officio*, a member of the consistory.

Education. The Belgian Government has shown itself thoroughly alive to the great importance of a general diffusion of education among the people. Numerous public schools and literary and scientific institutions are established throughout the country, supported out of the communal, provincial, or Government funds. Different classes of inspectors are appointed to visit and report upon the state of education in their various districts. Prizes, scholarships, and other rewards are bestowed upon those that distinguish themselves most in the prosecution of their studies. Religious and moral instruction is under the direction of the sect to which the majority of the pupils belong; but those connected with other sects may be exempted from attendance on this course. Normal schools have also been established for the purpose of securing trained and efficient teachers. The schools are open to all, and gratuitous instruction is provided for those who may not otherwise have the means of acquiring it. Yet, with all these advantages, there are still many among the lower classes growing up in ignorance. According to the census of 1866, out of a population of 4,827,833, only 2,279,891 were able to read and write, giving, if we exclude all of seven years of age and under, only 58 per cent. of the population. This proportion varied considerably in the different provinces, being as high as 77 in Luxembourg and 71 in Namur, and as low as 48 in East and 51 in West Flanders. In 1843 only 49 per cent. of those who took part in the balloting for the militia were able to read and write; in 1853, 56; in 1863, 62; and in 1873, 74. Out of 42,313 in 1873, 8678 were unable to read or write, 2027 could read but could not write, 13,887 were able to read and write, and 16,836 had received a superior education. This shows that it is not enough merely to provide the means of education in order to secure an educated population. In the industrial localities the parents are generally anxious to get their children admitted as soon as possible into workshops and manufactories, and in rural districts they are engaged in tending cattle or in field labour.

The educational institutions may be divided into four classes, viz., primary, middle, superior, and special.

A law passed in 1842 enacted that there should be at least one primary school in every commune, except in certain cases where primary education is already sufficiently provided for by private schools, or where one school may serve for several neighbouring communes. The communes may also adopt one or more private schools, possessing the legal qualifications, to occupy the place of the communal school. The branches taught are reading, writing, and the elements of arithmetic; the rudiments of the language spoken in the locality, -French, Flemish, or German; moral and religious instruction; and the legal system of weights and measures, in most schools taught practically. In many of the schools gymnastics, music, the elements of drawing, the outlines of history and geography, and the rudiments of the natural sciences, are also taught. The communes are obliged to afford gratuitous instruction to all the children within their bounds whose parents are in poor circumstances or are otherwise unable to educate them.

Primary schools. The primary schools are under the surveillance of the communal authorities and Government inspectors; and the imparting of moral and religious instruction is superintended by delegates from the religious bodies. Each province has a general inspector of the primary schools, who is appointed by the king, and inspects, at least once a year, all the communal schools in his district. Under him are the cantonal inspectors, who must visit the schools in their districts at least twice a-year. In 1872 the primary schools submitting to inspection were—communal, 3949; adopted, 469; private, 18; and boarding, 22; besides which there were 990 private schools and 230 boarding schools not under inspection. Of the inspected schools 1353 were for boys, 1284 for girls, and 1821 for both sexes; and of the non-inspected 267 were for boys, 693 for girls, and 261 for both sexes. The total number of primary schools was 5678, giving on an average 2·21 schools to each commune and 1·13 to each 1000 of the population. The total number of scholars attending these schools was 618,937 (or 12·3 per cent. of the population), of whom 313,165 were boys and 305,772 girls; 518,141 were at inspected schools, and 100,796 at non-inspected. The number of scholars attending the communal schools was 449,940, of whom 325,432 were instructed gratuitously; and attending the adopted schools 63,594, of whom 42,521 were receiving gratuitous instruction. The total number of teachers and assistants was 10,629, of whom 5394 were males and 5235 females; of these, 4656 males and 2977 females were in the communal or adopted schools. The teachers in the communal schools are appointed by the communal councils, which have the power of suspending them for a period not exceeding three months, the Government decreeing as to their absolute dismissal or reinstatement. They are required to have attended, for at least two years, the classes of a normal school.

Besides the primary schools properly so called, there are in many localities other establishments where primary instruction is communicated, as the infant, adult, manufacturing schools, &c. The infant schools are for children between two and six years of age. There were in 1872, 780 of these schools, of which 212 were communal, 220 private but under inspection, and 348 private and non-inspected. The total number of pupils was 78,181.

In the adult schools the branches taught are generally the same as in the communal primary schools. The communal councils are invited to establish such schools, and of late years considerable progress has been made in this direction. In 1863 the number of adult schools was 1194, with in all 188,890 scholars; and in 1872, 2351, with 199,957 scholars. In the latter year 1454 of the schools were communal, 74 private inspected, and 823 private non-inspected. Of the scholars 98,558 were males, and 101,399 females; 56,880 were at communal schools, where 54,630 were receiving gratuitous instruction, and 7362 at adopted schools, where 7179 were gratuitously instructed. There are also primary schools annexed to prisons, hospitals, and depôts of mendicants, and reform schools. The number of these in 1872 was 97, and of scholars 6485. Considerable sums are given by Government for providing food, clothing, and other necessaries for the poor children attending the primary and infant schools.

The expenses of public primary education fall in the first instance on the commune; and in case of insufficiency of funds, the province, and finally the state, come to its assistance. Each commune, however, must contribute a sum equal to at least two per cent. upon its direct taxation before being entitled to claim any assistance from the province or state. The total expenditure for public primary education was,—in 1843, 2,651,639 francs; in 1853, 4,465,411; and in 1863, 9,372,259. In 1872 it was 16,200,843 or £648,033, of which 1,326,659 francs were school fees received, 506,512 public or private donations, 5,863,561 were contributed by the communes, 1,584,010 by the provinces, and 6,643,415 by the state.

Middle schools. The middle schools are divided into two classes, those supported by the Government, and those maintained by the communes. The former are of two kinds—(1), the royal athenæums, called also the middle superior schools; and (2), the middle inferior schools, or the middle schools properly

so called, including the former superior primary, as well as the schools formerly known as industrial and commercial schools.

There are ten royal athenæums, two in Hainault, and one in each of the other provinces, viz., in the towns of Antwerp, Brussels, Bruges, Ghent, Mons, Tournay, Liége, Hasselt, Arlon, and Namur. In each of these are two courses, the one for the humanities and the other for a professional education. The professional course is divided into a lower division, comprehending a course of three classes, each of one year, and an upper division, with three sections, the commercial, industrial, and scientific, each divided into two classes, and extending over two years. In 1872 the number of students at the athenæums was 3562, of whom 623 were in the preparatory classes, 1157 in the humanity section, and 1782 in the professional.

In the state middle schools the courses are arranged so as to occupy three years. To some is annexed a preparatory section, making a year more. The number of these schools in 1872 was 50, with 9012 scholars.

The communal middle schools are of two grades, a first and second,—the former embracing 17 schools, the latter 16. They ought to be based upon the same principles, and teach the same branches as the royal athenæums and middle schools. In 1872 the number of scholars in the first or higher grade of schools was 1381, of whom 239 were in the preparatory classes, 730 in the humanity section, and 412 in the professional. The number of scholars in the lower grade of schools was 1828, of whom 1274 were in the lower sections and 554 in the higher. Most of these schools have libraries, museums of natural history, and chemical laboratories attached to them. There are in addition to these 75 unendowed colleges, of which 45 are Episcopal and 11 Jesuit.

The educational staff consists of a prefect of studies in the athenæums, and a rector in the middle schools, professors, regents, and masters. The prefects, professors, rectors, and regents are nominated by the king, and the masters and teachers by the minister of the interior. The diploma of a professor *agregé* of either degree is bestowed by a special jury after a searching examination. It is given without regard to the place where the candidate has studied. The prefects and rectors reside on the premises, and have the general direction and management of the institutions over which they are placed. Each has to report annually as to the state and condition of the institution under his care, and to register the conduct and progress of the scholars.

The middle, like the primary schools, are subjected to a regular system of inspection. The literary and scientific branches are under the superintendence of two inspectors and an inspector-general nominated by the king. To one of the inspectors is especially confided the mathematical and natural sciences, and to the other the humanities; the other branches, as history, geography, and the commercial sciences, may be committed to either of the inspectors or to the inspector-general. The inspector has to examine and report upon the state and discipline of each establishment, the methods employed in teaching, the progress made by the pupils, and the merit and zeal of the teachers. The *conseil de perfectionnement* for the direction and improvement of middle education is composed of from eight to ten members, mostly professors in the universities, presided over by the minister of the interior or his deputy, and meets at least four times a year. A general competition takes place annually among the scholars of the athenæums and colleges receiving grants from Government, to which, however, scholars from other establishments may be admitted. The examinations are both written and oral; and the rewards are of three kinds, prizes, *accessits*, and honourable mention.

The amount contributed by the state to the athenæums in 1872 was 467,575 francs, to the state middle schools 418,589, and to the communal middle schools 184,079. The amount contributed by the communes to the athenæums was 291,937 francs, to the state middle schools 169,320, and to the communal middle schools 232,359.

The superior instruction establishments are the four universities,—two belonging to the state, at Ghent and Liége, the free university at Brussels, and the Catholic university at Louvain. Universities.

Each of the state universities has faculties of philosophy and literature, science, law, and medicine. In each there are 8 professors in philosophy, 9 in the sciences, 7 in law, and 8 in medicine. One or two additional professors may be added to each of the faculties in case of necessity. The professors are nominated by the king, and cannot exercise any other profession without the consent of the Government.

Attached to each university are a number of *agregés* named by the king. Their title is honorary, and they are chosen from among those students who have most distinguished themselves at the public competitions or final examinations, from professors of middle instruction, or from members of the civil or military body of engineers. They are nominally attached to one of the faculties, but are not prohibited from exercising any of the liberal professions, and in case of any of the professors being unable to perform his duties, a substitute is chosen from among the *agregés* attached to that faculty.

The universities are under the management of a rector, a secretary, deans of faculty, the senatus academicus, and the board of assessors. The rector is nominated by the king for three years, and has the direction of all academic matters. The secretary is appointed annually by the king from a list of two candidates nominated by the senatus academicus. The deans of the faculties are chosen annually by the professors of each faculty, and have the right of convoking the professors of their faculty. The senatus and the board of assessors are convoked by the rector; the former is composed of the professors, under the presidency of the rector, and the latter of the rector, secretary, and the deans of faculty.

Each student pays annually for enrolment 15 francs, and then takes out a ticket for the branches of the course in which he intends to take his examinations. For philosophy and literature, and for law, the annual ticket costs 250 francs, and 200 francs for the other faculties. The instructions are given in the French language. Subsidies are accorded by Government to the universities for the libraries, botanical gardens, cabinets, &c.; but the towns of Liége and Ghent are bound to maintain the buildings. The sum granted by the state to the two universities in 1873 was 937,919 francs.

Attached to the university of Ghent is a school for civil engineers. The preparatory course extends over two years, and comprehends the mathematical, physical, and natural sciences necessary to the subsequent courses. The special course is divided into two sections, the one for engineers of roads and bridges, and the other for architectural engineers. This course continues for two or three years. The third course, which lasts for three years, is for industrial engineers or persons engaged in arts or manufactures. They are instructed in the application of the various sciences to the arts and manufactures, particularly to the mechanical arts.

Similar to the above is the mining school attached to the university of Liége. The first course is preparatory to the other two. The special course includes all the branches necessary to a mining engineer. The third course is for those desirous of obtaining a knowledge of mining, min-

erals, &c., more particularly as connected with the arts and manufactures. This last course extends over three years.

The free university of Brussels has faculties of philosophy and literature, of science, of law, and of medicine, courses in which are given by ordinary and extraordinary professors and *agregés*. Each student pays annually 15 francs for enrolment, and a fee of 200 or 250 francs for the courses in any of the faculties. The fee for single classes is generally 50 francs. An annual subsidy of 10,000 francs is allocated to the university by the provincial council of Brabant, and the permanent deputation has the right of annually presenting ten youths of the province for gratuitous instruction. A subsidy of 50,000 francs is also allocated annually by the communal council of Brussels. The university is governed by an administrative council, composed partly of permanent members and partly of members chosen annually by the professors of the four faculties and the former students of the university. This council is presided over by the burgomaster of Brussels, who has a casting vote in its proceedings.
